When an acute inflammation of any part of the body develops, the tissues involved become more inelastic than in the normal state. This we find to be the case in the wall of the duct of Bartholin. The duct if probed is found to be capable of less distention than when not inflamed. Now with the subsidence of the acute inflammation the plastic material, deposited in the walls of the duct, is more or less absorbed. If all inflammation subsides after persisting for only a short time, after an interval more or less variable in each individual, all the inflammatory material is ultimately absorbed, speaking from a practical standpoint, so that the duct is comparatively normal. Should the acute inflammation be followed by a chronic inflammatory process, only partial absorption of the inflammatory material in the walls of the duct occurs, and the remainder, as the result of persistent irritation and increased blood supply is augmented, and ultimately organized into firm connective tissue.

The inflammation has produced an inelastic and less distensible duct. Its lumen is further diminished by the contraction of the connective tissue, and by the encroachment upon the lumen of the canal of the connective tissue and the inflammatory tissue, which together in some cases form more or less of a distinct mass.

A chronic inflammation of the duct may have persisted for a considerable time without the formation of a distinct stricture at any point or points in the duct, but in the great majority of instances when we have slit the orifice of the duct, we are able to demonstrate a contraction somewhere along the course of the duct.

The course and importance of stricture of the duct of Bartholin and stricture of the urethra

must not be confounded. In urethral stricture we have a strong stream of irritating urine being forced past the stricture every few hours. The urinary stream in the urethra keeps up a constant irritation, and there is in a great many of the cases an extravasation through minute points in the urethral wall. These extravasations play no small part in increasing the pathological process.

If the stricture in the duct of Bartholin causes no appreciable damming back of the secretions of the gland or of the solutions used in irrigating the duct, such stricture is not likely to interfere with the success of the treatment. We must remember that it is most difficult to say that the stricture is not interfering with the passage of secretions, and as they are likely to become inspissated so as to plug the canal at this point, it is well whenever possible to overcome the stricture.

This dilatation of the stricture or strictures can be accomplished with probes of various sizes. Before using probes which pass only with resistance through the stricture, a four per cent. solution of cocaine should be injected into the duct. This permits us to probe more freely and with less discomfort to the patient.

In these cases the gland will almost invariably be palpable and the probes are directed from the external orifice of the duct directly toward the gland. No considerable amount of force should be used in these cases, as we may in probing the lacrymal passages, for here we have no bony canal surrounding the duct, and force will almost invariably result in the formation of a false passage. A false passage with the instruments at present at our disposal means that the stricture cannot be dilated successfully unless we wait until the false passage has healed, as the probes will invariably follow it.

The probes used by Theobald in dilating the lacrymal passages may be used, or graduated sizes of probes may be secured from the instrument dealer for the purpose. The tip of the probe should taper. We should continue the dilatation until a size is reached about an eighth of an inch in diameter. Sometimes a size one sixteenth of an inch in diameter cannot be exceeded. If such proves to be the case, the irrigations should be continued after this size has been reached, as has been previously described. After each probing the duct should be washed out with an antiseptic solution. The probing can usually be repeated every second day, but if much irritation is excited the interval should be lengthened.

Where the gland is not palpable, and the infection seems to be in the duct alone, it may be well to exercise considerable care in using irrigations of the duct, in order that an irritation and inflammation of a healthy gland be not excited. Milder solutions, such as the boric acid solution, should be tried first and they should be injected gently so as to avoid irritation of a gland which may be entirely healthy. If the agents fail which are unirritating, we should then try the effects of astringent and antiseptic solutions.

In probing the duct, we sometimes mistake the opening of one of the follicles found in the vestibule for the opening of Bartholin's duct. Five or six of these follicles are found on each side, and have been called "the glandulæ vestibulæ minores." If a very fine probe fails to pass more than one fourth of an inch, and there is no evidence of a retention cyst in the labia, we may safely assume that the probe is not introduced into the duct of Bartholin, but into one of these follicles. When the gland is distinctly enlarged and easily palpable, we can massage the gland gently before probing and before the injection of our antiseptic and astringent solutions. This massage should not be violent and painful and should only be used in the absence of an acute inflammation of the gland.

The use of the silver nitrate solution, or some of the other salts of silver, or astringent or irritating solutions of any kind, will keep up a discharge of stringy, not entirely colorless mucus from the walls of the duct or gland. After these irritating agents have been used for two or three weeks we should again revert to the boric acid solution. If after two or three weeks we find that the discharge persists, the patient is not cured, we must either return to the stronger solutions or take the more radical step of excising the affected gland.

(To be continued.)

The New Army Hospital.—Secretary Taft has approved the recommendation of Surgeon General O'Reilly for the erection of a new general army hospital on the Cameron tract on the west side of Brightwood Avenue, Washington, D. C., nearly opposite the Battle National Cemetery. Congress fixed the limit of cost of this hospital, including site, at \$300,000, and appropriated \$100,000, which was made immediately available, for the purchase of the site. The property acquired for the purpose contains about forty-three acres and cost about \$98,000, leaving \$2,000 of the appropriation to be devoted to other expenses in connection with the new building.

ATONY OF THE RECTUM AND ANAL SPHINCTERS: ITS ÆTIOLGY, PATHOLOGY, DIAGNOSIS, AND TREATMENT.

By WILLIAM BODENHAMER, A. M., M. D.,

NEW ROCHELLE, N. Y.

(Concluded from page 699.)

TREATMENT OF RECTAL ATONY.

In the treatment of defective muscular power of the rectum, it is of importance not only to be able to recognize the true nature of the malady, but, above all, to know also the most rational and effectual measures for its relief. The first consideration in the treatment of this affection is to enjoin a strict observance of regular habits respecting or regarding a daily evacuation of the rectum, and this desirable object in mild cases may be aided and often attained by simple means, such as the injection of from half to a pint of cold water of the ordinary temperature, into the rectum at the regular time of going to stool every day. This constitutes a most valuable remedy in atony of the rectum. Cold, being tonic, stimulant, and astringent, acts some what similarly to nux vomica by exciting the sensibility and contractility of the organ, but it should be discontinued as soon as the object of its use has been attained.

In the more obstinate cases, however, the chief remedies should be nux vomica alone or combined with some other drug, together with the employment of rectal injections composed of powerful astringents and tonic substances, with the intention of inducing contraction, corrugation, and condensation of the relaxed and weak muscular fibres of the rectum, by which they become shorter and firmer, and thus aid in diminishing the morbid organ to its normal dimensions and tone. The exhibition of proper aperients as adjuvants is indicated in some of these cases, and cannot be dispensed with, especially when atony of the colon exists with that of the rectum. But drastic purgatives should not be used in such cases. The smallest dose of an aperient should be given, so as to gently rouse the normal peristaltic action, and its use continued only until a habit of daily evacuation is induced. The object is by no means to excite watery stools, but to induce, as much as possible, an imitation of the normal action of the bowels; indeed, the best and only method of maintaining a regular action of the bowels, after the habit has been reestablished, is to compel them, if possible, to perform their own legitimate work, by withholding aperients, as well as all other artificial means generally used for this purpose. With regard to the ingredients composing the astringent and tonic injections to be used in the treatment of atony of the rectum, such sub-

stances abound, and may be varied indefinitely by the practitioner. These injections should not exceed in measure more than five or six ounces, and should not be administered until the rectum has been previously emptied of its fecal contents by a proper enema or an aperient. The astringent injection should be given once daily at least and retained for a few minutes, if possible, but if it cannot, and is passed at once, it will nevertheless do good. In obstinate cases it may be of advantage to add from half to a grain of nux vomica to each injection. The writer has used with good results in some of these cases, the decoction of galls, as well as the strong decoction of white oak bark and alum. He also used the following:

R Tannic acid.....30 grains;
Red wine.....4 ounces.

M. For an injection.

M. Bretonneau, in order to correct the morbid condition of the rectal pouch in these cases, which he called *rectal constipation*, and which he often found to be complicated with anal fissure, used with signal success, according to the testimony of his eminent pupil, M. Trousseau, the following injection, which not only restored the organ to its normal action, but also cured the anal fissure when both affections coexisted:

R Extract of rhatany.....2 drachms;
Alcohol.....5 drachms;
Distilled water.....5 drachms.

M. For an enema.

The writer has employed the injection of Bretonneau with success in a number of cases, and among them several in children, in which about one fourth of the quantity was injected.

In some of these cases the following pill, or a somewhat similar one, may be used with good results, especially if atony of the cæcum exists with that of the rectum, so as to excite the peristaltic action and soften, if possible, the hard fecal matter in the former, as it cannot in its entirety, be so easily reached by injections. These pills produce an easy evacuation. One pill should be taken daily at dinner or at bedtime:

R Extract of aloes.....30 grains;
Extract of nux vomica.....20 grains;
Extract of hyoscyamus.....15 grains;
Ferric sulphate.....10 grains;
Oil of cloves.....5 drops.

M. For 30 pills.

The extract of nux vomica may also be given alone with advantage, once daily, as a pill of from one half to one grain. The inspissated ox gall is also very valuable.

The writer will here give an interesting case of atony of the cæcum, coexisting with that of the rectum, in which these organs were found impacted with large collections of indurated fecal

matter, and which seemed to indicate some serious chronic disease in the right ilioinguinal region.

Mr. J. R., of New York, of a bilious and nervous temperament, consulted the writer in 1890. He said he was suffering from an almost constant dull ache in the right groin, which he was told indicated appendicitis, and that he discharged much turbid and offensive urine, which he feared denoted Bright's disease of the kidneys; and said he: "Doctor, with appendicitis upon the one hand and Bright's disease upon the other, I feel and fear that I am between the devil and the deep sea." He also said that he suffered much from obstinate constipation of the bowels, frequently having no evacuation for three or four days, and being a strong believer in homœopathy, he had declined to take purgative medicine for their relief. It was soon made evident, however, that all the afflictions of Mr. R. were the result of atony of the cæcum and rectum, together with the injurious effects of the long retention and distention of the impacted fæces in these parts of the large intestines. Careful palpation of the right ilioinguinal region, directly over the cæcum, disclosed a decided fullness and hardness or firmness with some unevenness of surface; upon firm pressure there was, however, but little soreness complained of. Nothing abnormal could be detected directly in that now much dreaded and fearful locality, the *appendix cæci*. The ensemble seemed, therefore, to indicate the commencement of some serious chronic affection, especially of the cæcum; and while reflecting upon the obstinate confinement of the patient's bowels, the idea occurred that it might be atony of the cæcum, as well as of the rectum, caused by cæcal impaction or repletion of fæcal matter; acting upon this impression, the patient was at once directed to take three ounces of castor oil in the morning on an empty stomach, and, should the oil fail to act in three or four hours, to repeat the dose, and in the meantime to remain in the house and wait for events. The result was that in eight hours after taking the oil his bowels were completely relieved of large quantities of indurated and offensive fæces. This somewhat obscure case was now made clear by the entire absence of the abnormal fullness, hardness, and unevenness of the cæcal region, as well as the dull ache complained of in the same locality. In order to prevent a similar recurrence, and to cure the affection, the aperient pills described above were used by the patient for some time with the most happy results.

MECHANICAL REMOVAL OF IMPACTED FÆCES.

In cases in which the rectum or rectal pouch is firmly distended and blocked by a large, hard fæcal bolus, or by a large, pulposus, and tenacious mass, which neither purgatives nor stimulating injections will have any effect toward softening the former, nor dissolving and removing the latter, the only remedy is the employment of mechanical means. After dilating the anal sphincters well under ether if necessary, the finger, with

the aid of the rectal curette, should be used to break up and remove as much of the impacted mass as possible, and the remaining fragments should then be completely washed out by stimulating injections. Mr. John Woodall, an English surgeon, two centuries ago invented a rectal scoop or curette for removing and cleaning the rectum of hard or soft or tenacious fæces, which he called *spatula mundans*, or *mundator ani*. To all these means in the treatment of atony of the rectum must necessarily be added as auxiliaries, a proper diet, claret, active exercise in the open air, on foot, horseback, or bicycle.

ATONY OF THE ANAL SPHINCTERS.

The loss of tone of the sphincters of the anus, like that of the rectum or rectal pouch, and from somewhat similar causes, sometimes occurs and consists of the loss of power to some extent of their muscular fibres. In such cases, although the sphincters lose a large portion of their tonicity, yet their functional power is not altogether destroyed, as it is in paralysis, the result of paraplegia, in which both their grasping and retentive functions are entirely lost, so that the dejections, if fluid, will, on reaching the sphincter, escape involuntarily. The anal sphincters are much less frequently the seat of atony than the rectum, but the affection in both may and does occasionally exist. When the sphincters are affected, the disease is more readily detected, being external; but when the rectum is the seat of the affection, it is much more liable to be overlooked, being internal.

Atony of the sphinctores ani frequently occurs in old age, and in such cases it is commonly called palsy, or local paralysis. It is a very troublesome and distressing malady, and is often attended by prolapsus recti and eversion of the anus, and sometimes it entirely prevents the aged patient from taking exercise on foot. In such cases, during the treatment the patient should evacuate his bowels just at bedtime, for if they are emptied in the morning the patient either moves about on his feet or remains in the sitting posture, by either of which irritation is kept up all day; whereas, when the evacuation takes place at bedtime, the patient remains in the recumbent posture for many hours, and is enabled in the morning to exercise without the parts protruding for hours. This, to repeat, is one of the worst forms of atony of the anal sphincters, if it may in reality be so called, being so closely allied as it were to partial paralysis that it is difficult to distinguish between it and such an affection. This form, however, in these cases is generally without any marked disease in the nervous cen-

tres affecting other functions also. Atony of the anal sphincters is often met with in some hysterical women, and also among hypochondriacs, and it occurs sometimes in infancy and childhood.

ÆTIOLOGY.

Among the causes of this affection may be mentioned exhaustion from protracted ill health; sedentary habits; immoderate use of alcohol and tobacco; excessive or repeated dilatation of the anus, produced by the straining efforts at evacuation in chronic dysentery; divulsion of the anal sphincters, either for therapeutic or diagnostic purposes. The affection is sometimes produced by a descent or a prolapsus of the rectum, or by hæmorrhoidal or other tumors of the same, which by their continued pressure within and their frequent passage out and in through the anal orifice, impair the contractility of the anal sphincters. It may be observed, however, that in such cases, as a general rule, the removal of the cause will restore the sphincters to their normal tone. Among the most fertile causes of anal atony, according to some authors, may be mentioned pæderasty. By the action of the external sphincter, the skin of the anus is disposed into radiated plaits, with intervening furrows, which extend some little distance into the anal canal, as well as out on the external surface. In the worst cases of atony of the sphincters, these folds almost or entirely disappear or become effaced; the margin of the relaxed anal orifice will be found loose and salient, so that the finger or bougie can be passed through the anal orifice and into the rectal pouch without meeting resistance. When the atony is the result of the vicious practice, the anus is much excavated, as it were, and presents the aspect or appearance of a funnel. In all cases of anal atony there is a slight escape or oozing of fecal matter for a short time after each evacuation, so that it is impossible to observe cleanliness.

TREATMENT OF ATONY OF THE SPHINCTERS.

In the treatment of the ordinary cases of atony of the anal sphincters, the cold water ascending douche is a most valuable remedy in restoring their lost tone. It should be applied to the anus forcibly for four or five minutes directly after each evacuation of the bowels, and once or twice besides, during the day. The following ointment or lotion may be used with advantage in such cases:

B. Sulphate of strychnine.....	10 grains;
Rosewater ointment.....	1 ounce.
M. For an ointment.	
B. Extract of nux vomica.....	8 grains;
Alcohol.....	2 ounces;
Ammonia water.....	1 drachm.
M. For a lotion.	

The writer will conclude by asking pardon for the length of his paper, which doubtless appears too prolix; and it may also seem that his descriptions, physiological, critical, operative, etc., are unnecessarily minute in their details. But the writer would remark here, that it is often the neglect of minuteness and the eagerness or fondness for generalization which involve a subject in obscurity. So long, however, as we adhere closely to facts we cannot be too microscopical, for facts or truths, however, simple, are just as essential to refute false opinions as they are to establish true principles.

Ireland Honors Professor Osler.—Dr. William Osler, Regius Professor of Medicine at Oxford University, has been elected an Honorary Fellow of the Royal College of Physicians of Ireland.

ERYTHEMA AND URTICARIA, WITH A
CONDITION RESEMBLING ANGIO-
NEUROTIC ŒDEMA, CAUSED
ONLY BY EXPOSURE TO
THE SUN'S RAYS.

By S. B. WARD, M. D.,

ALBANY.

Miss H., an American by birth, 47 years of age, native of the United States and residing in Albany, consulted me in October, 1904, on account of a very annoying eruption which appeared every time that she was exposed to the sun's rays.

In the *American Journal of the Medical Sciences*, for 1895, in Jacobi's *Festschrift*, and in the *American Journal of the Medical Sciences*, for January, 1904, Dr. Osler has brought together twenty-nine cases which he entitles On the Visceral Manifestations of the Erythema Group of Skin Diseases. The cases are in some respects very different, but all have in common the character of a skin eruption. In the course of his article, Dr. Osler points out that there appear to be three causes for the cases which he reports: first, a variety of poisons; bacterial, protozoal, vegetable, and metabolic; and in the second place he says that "the chronic forms of urticaria probably illustrate a morbid and persistent sensitiveness of the cutaneous vessels to poisons of either intestinal or tissue origin; and, thirdly, the importance of the local status is shown in that remarkable form of urticaria which comes on after the exposure to cold. So long as the face is at a temperature of above 60° F., the patient is all right; exposure at 40° is felt at once by an outbreak of urticaria."

The case which I am about to report gives no evidence of any serious intestinal trouble and no nephritis. The peculiarity of it is that since June, 1903, the eruption has appeared almost every time that her skin is exposed to the direct rays of the sun.

Previous History.—She had scarlet fever at three or four years of age; she has never had acute articular rheumatism, but has had several attacks of lumbago and rheumatism of other muscles. She has had many sorrows and anxieties; has always been "nervous," though apparently very calm. The menopause came on in 1900 and is only just now completed. She has long been conscious of irregularity and intermissions in the heart beat; never has become unconscious, but has faint feelings, without dizziness; has no serious indigestion, but there is occasional development of gas in the digestive tract and she has noticed that at those times her heart is more troublesome. She is stout and very strong, robust looking. She has moderate hypertrophy of the heart, with no murmur whatever. There is an occasional double beat, followed by an intermission, of which the patient is herself conscious.

On June 1, 1903, while working in the garden, there appeared on both arms and the back of the

neck markedly elevated white patches and streaks accompanied by very severe itching and burning. The next appearance was on the twenty-second day of the same month, when the eruption was confined mostly to the forehead. In August of the same year, while rowing an Adirondack boat, it appeared again, and this time on the ankles also, which were accidentally exposed by the skirt being pulled up a little. In the autumn of 1903 the itching began to come almost every time that she went out of doors. About one day in twenty during the past year she has been able to go out of doors without the eruption appearing; the nineteen other days it is certain to come. At times it appears also if clouds conceal the sun and the wind is blowing. It appears only on the exposed parts of the body and those covered by only one thickness of clothing; two thicknesses appear to prevent it. All last summer it would appear on parts protected only by a shirt waist, but a light jacket over the shirt waist would prevent it. A thick veil prevents its appearance on the face, and gloves protect the hands. Walking in the street, she saves herself a great deal by always walking on the shady side. If she remains out of doors more than about an hour, the eruption will gradually disappear and not return again during that exposure. On returning to the house after exposure, the eruption all disappears in a period varying from ten minutes to an hour, depending on the length and degree of the exposure.

On November 18, 1904, in order that we might have a good opportunity to examine the eruption, in the presence of Dr. H. C. Gordinier, of Troy, and myself, she voluntarily, after removing her dress waist and leaving the shoulders, chest, and arms exposed about as they would be in evening dress, sat near a south window, through which the sun was streaming in. Prior to the exposure the temperature under her tongue was 98.6°, pulse 88, respiration 16, and temperature of the surface of the arm 87.0°. The whole left arm and a portion of the front of the chest were then exposed to the direct rays of the sun for a period of five minutes. She then went into a front room where there was a good light, but no sun, and the following conditions were noted: temperature under the tongue was 98.6°, pulse 88, respirations 17; but the temperature of the skin of the exposed arm was raised to 96.8°, nearly 10°. The unexposed portions of the skin had undergone no changes whatever. The exposed portions were of a uniform brilliant scarlet color as if the subject of scarlet fever. The skin was swollen to such an extent that there was some impediment to flexion at the elbow joint. The hairs all stood up straight in marked contrast to the other arm, and the sensation of burning was complained of as intense. The condition was manifestly one of erythema. On parts of the arm, and especially on the front of the chest, there were present also about a dozen white, round wheals, like those of urticaria, varying in size from a large pin's head to a silver dime, accompanied by marked itching. These conditions of redness and wheals extended in a less degree downwards below the line of actual exposure, under one layer

of thin linen. Fifteen minutes later, the redness of the arm and burning sensation had markedly diminished, but the swelling was about the same, and the depressed orifice of every sweat duct was perfectly visible. On the front of the chest the redness had disappeared, the wheals had run together, and one large white patch, irregular in shape, some five inches long and two inches wide, showed the pores most plainly. The face, neck, and hands were of an almost uniform red color, somewhat blotchy, save that the neck showed a band of normal skin about two inches wide which had been protected by the shadow of the head; in other words, the parts of the skin usually exposed did not show the changes nearly as plainly as those that were usually covered. Tactile sensation and the perception of heat and cold were perfect. The conjunctiva of the left eye was injected, the small vessels becoming visible. After the lapse of an hour the skin everywhere resumed its normal appearance, except that on the front of the arm the capillaries remained dilated, but the sensations of burning and itching were all gone.

The blood count made at about this time showed 3,975,000 reds and 5,400 whites. The reds were somewhat crenated; hæmoglobin, 90 per cent.; color index, 1.1 per cent. Janeway's sphygmomanometer showed a systolic blood pressure of 160 mm.

The urinary examination showed sp. gr. 1017; acid; no albumin; a few leucocytes; much ropy mucus, and some cylindroids.

On January 18, 1905, the bare arm was exposed for ten minutes to the x rays at the Albany Hospital, under the supervision of Dr. E. A. Bartlett, who has charge of the apparatus belonging to that institution. The tube was a new one and the machine was in every way working perfectly. Absolutely no effect whatever was produced.

January 23rd, was the first perfectly clear, bright day that we had had for some time and Miss H. was exposed for an unusually long period. For the first time her lips became so swollen as to be very uncomfortable (angeioneurotic oedema) and the swelling did not disappear for some hours after returning to the house.

That this eruption is not due to heat alone is proved by the fact that the patient can sit in front of a hot open wood fire by the hour without the least inconvenience.

On January 28, 1905, the patient was good enough to allow me to try the effect of yellow and red glass, such as photographers use to cut off the actinic rays. The left arm was bared. The upper portion was exposed to the direct rays of the sun, shining in through a southern window at 2 p. m.; a band three inches wide was protected by filtering the rays through yellow glass; another three inches by red glass; and a third three inches by both red and yellow, and the arm below these three bands was exposed as it was above them. The exposure was stopped at the end of five minutes, and the arm examined in bright diffused daylight. The exposed skin presented precisely the appearances above described

of erythema, urticaria, and cedema, with intense burning and itching. The band shaded by the yellow glass alone showed a moderate degree of redness without burning or itching. The other two bands showed no change whatever. This would appear to show that this curious disturbance is caused by the actinic rays.

That it is due to an unusual form of vasomotor disturbance appears clear. With each exposure, if it is short, we have an erythema; if more prolonged, urticarial wheals appear; and if still more prolonged an angeioneurotic oedema.

This case and the one quoted by Dr. Osler, in which case urticaria appeared every time that the skin was exposed to a temperature of 40° F., remind me of certain other cases in which there is no eruption, but in which the skin remains remarkably sensitive to changes of temperature after having been once frozen. In the winter of 1880, a girl here in Albany had her cheeks frost bitten. For three or four years after that, it was impossible for her to go out of doors in winter without having her cheeks frozen again unless they were protected by a heavy veil. Thirteen years later, in the autumn of 1893, I was riding on horseback with her one afternoon when the thermometer was at about 35° F. We were riding in a wind which was not very strong, and a little squall of snow struck us. Within two minutes she said that her cheeks were becoming frozen. It did not seem to me to be possible; but examination showed that both cheeks were cold, perfectly white, and beginning to be stiff. Turning homewards, with our backs to the wind, the condition passed off in about ten minutes and the cheeks were flaming red. It would seem as if this must have been a case in which the vasomotor constrictor nerves had been rendered unusually sensitive by the first exposure and remained so for many years. They appear to have recovered now, for within the past two years she has been able to stand any ordinary exposure as well as most persons.

In conclusion, it would appear that in rare instances the vasomotor nerves may be so influenced by the actinic rays of the sun, or by moderate cold, as to be afterwards readily thrown into a condition of spasm or paralysis.

281 STATE STREET.

Bequest for a St. Paul Hospital.—The will of the late Edward Giboney has been filed for probate in the office of the clerk of the probate court. The will provides a bequest of \$1,000 to go to Mother Bernardine, of St. Joseph's Hospital, the money to be used in the building of a chapel at the hospital. The balance of the \$5,000 estate is to be divided between the natural heirs.

A CONTRIBUTION TO THE ALCOHOL
QUESTION.*By S. P. BEEBE, PH. D.,
NEW YORK.

The very large use of alcoholic beverages has a tremendous influence, physical, economical, and moral upon society, and this has led to a prolonged discussion as to the physiological effect of alcohol and its therapeutic value. It is of vast importance to the State that the truth in regard to its physiological effect shall be known and taught; not only because of the very large number of persons who knowingly drink moderately, and the smaller number who drink excessively, but also because of the widespread use of alcoholic preparations, such as patent medicines, by persons who presumably are not in vigorous health. Leach, chemist to the Massachusetts State Board of Health, analyzed many of these preparations advertised as entirely harmless, recommended for inebriates, containing no alcohol, etc., and found alcohol in quantities varying from 7 per cent. to 47 per cent. Again, Harrington's analyses of certain proprietary foods for the sick, by which he found a quantity of alcohol varying from a minimum of 10.6 to a maximum of 23 per cent. in foods which are prepared expressly for invalids or persons weakened by disease, the quantity to be taken in twenty-four hours in some cases equaling six ounces of whiskey, affords striking evidence of the mischief which may be wrought by unwittingly prescribing this substance.

It is the writer's purpose to give in this paper a brief review of the present status of the discussion in regard to alcohol together with the results of a series of experiments devised to afford further light on its physiological action. It may as well be stated at the outset that this discussion is chiefly concerned with the effects of the so called moderate use of alcohol. Excessive drinking is admitted to be harmful not only by physiologists, but by all sensible persons. The moderate drinker, however, enjoys a sense of security which has been fostered by medical and lay opinion for generations, and there are a great many physicians at the present time who believe and advise their patients that moderate drinking *per se* results in no bodily harm. It is of interest to note that the maximum quantity of alcohol which may be classed as a moderate quantity, has steadily diminished during the last fifty years. At the present time 70 cubic centimetres of alcohol in twenty-four hours, corresponding to about six ounces of whiskey, is considered by

most physiologists to be near the upper limits for the moderate drinker.

Many experiments have been made to determine the fate of alcohol in the body. It was believed up to a comparatively recent time that alcohol was not oxidized in the body, but was excreted unchanged by the lungs, skin, and kidneys. This view was held because no specific oxidation products could be found in the excretions. The same objections apply to sugar, which is undoubtedly oxidized in the body. The recent experiments by Atwater and Benedict with the respiration calorimeter have shown that when the daily dose of alcohol does not exceed 72.5 grammes not more than 2 per cent. leaves the body unchanged, the 98 per cent. being oxidized into carbon dioxide and water. Such being the case the potential energy of the alcohol must be available for use in the body for supplying heat, doing work, or in sparing body tissue. We can scarcely conceive of the simple molecule of alcohol being used in a synthetical process for building up body tissue so that whatever food value it has depends upon the energy liberated during its oxidation. The careful respiration experiments of Zuntz and Geppert have shown that the amount of energy used in its absorption is less than that yielded by its oxidation, leaving a net per cent. for body uses as great as that yielded by other forms of food.

The very careful experiments of the last few years by men who have approached the subject from opposite opinions have led to the following concordant results:

First, alcohol may take the place of some fat or carbohydrate in the food.

Second, when taken to replace isodynamically (i. e., a quantity of alcohol having the same potential energy as the food replaced) a given amount of fat or carbohydrate in a body unaccustomed to its use, it causes for a few days, three to six, an increased excretion of nitrogen. This may be due to what Neumann calls its action as a protoplasmic poison. During these few days the body gradually acquires a tolerance for this poison, as it does for a great many other toxic substances, and the energy from its oxidation is then available for bodily needs to the same extent as the food it has replaced. [As a good example of such a toleration being acquired we may cite the instance in one of Neumann's experiments where a perfectly healthy man took each morning for a period of sixteen days 100 cubic centimetres of alcohol diluted with 300 cubic centimetres of water. This caused during the first few days a period of marked intoxication, but by the eighth day such an effect was no longer pro-

* Read before the Section in Medicine, Academy of Medicine.

duced, and from the twelfth to the sixteenth day the experimental subject was only mildly exhilarated and took with some degree of pleasure the portion which was at first quite distasteful.]

Third, alcohol is an extraordinary food to be used only in certain conditions when its ease of oxidation may be of great benefit; but on account of its peculiar toxic effects it should not be taken except when needed. This last statement is worthy of some emphasis, because it is a point upon which all physiologists who have studied the matter agree and also because it is the one point of most caustic criticism by certain of the laity. The term food is in a sense a technical one for the physiologist, and the conclusion that alcohol may be under certain conditions a food substance, does not argue that it should be used widely and indiscriminately. A society of marine engineers might willingly grant that the furniture of a ship, together with its decks and stanchions, were fuel substances, yet no sane captain would use them for such purposes except in the direst need.

The foregoing conclusions have been derived from a very large number of feeding experiments in which the income and outgo of matter and energy were carefully determined. In such experiments the most important single factor is the accurate determination of the nitrogen balance, for by so doing we know whether body tissue has been built up or broken down during a given period. If we find an increased nitrogen excretion as a result of substituting alcohol for its energy equivalent in fat or carbohydrate in an animal in nitrogenous equilibrium, we know that body tissue has been broken down, and that the alcohol has not completely replaced the food for which it was substituted. All of the conclusions from experiments regarding the food value of alcohol depend upon the determination of the total nitrogen excreted in the urine. Such an estimation can be made at the present time by methods that are beyond reproach, yet the determination does not, in the opinion of the writer, tell the whole story of the effect of alcohol on the proteid metabolism in the body, for it gives no clue to the distribution of this nitrogen among the several normal constituents of the urine.

The nitrogen excretion of the urine is divided among several compounds; three of the most important being given in the following table. In health:

85-90 per cent. of the total nitrogen appears as urea.
2.5-5 per cent. of the total nitrogen appears as ammonia.
3-5 per cent. of the total nitrogen appears as uric acid.

Small quantities of a great many other nitrogenous substances are found even in healthy urine. In certain diseases of the liver, acute yellow atrophy,

or carcinoma, the same quantity of nitrogen may be excreted as in health, but a portion of it will be in the form of the amino acids, leucin, and tyrosin, compounds never found in healthy urine, and the detection of these may give proof that the liver is involved. This impairment in function may show itself in an abnormal distribution of the nitrogen among the several physiological constituents. Thus, in puerperal eclampsia there is a diminution in the urea and a corresponding increase in the ammonia nitrogen, both ammonia and urea being normal constituents, and the pathological condition is expressed by their being present in a different ratio than in health. May it not be that alcohol shows its toxic effect by impairing the metabolic functions of certain organs not to a sufficient degree to change the total nitrogen, but marked enough to show itself in the forms by which this total amount is excreted?

The writer has recently completed a series of experiments designed to throw some light upon this phase of the question. The subjects for the experiments were young men in good health unaccustomed to the use of alcohol in any form. The diet was carefully regulated to prevent error from that source, for we know now that the character of the diet has a vast influence not only upon the amount of nitrogen excreted, but also upon the form in which it appears. Neglect of care in this regard vitiates many of the older experiments. The habits of the subjects were uniform throughout, no unusual work or strain of any sort interfering with the normal routine. The quantity of alcohol taken was in no case excessive, and in nearly every instance it was within the limits of moderate drinking.

EXPERIMENT I.

In any such experiment there are three periods: The fore period which serves to establish the normal condition of metabolism, the alcohol period during which a known quantity of alcohol is added to the diet and the effect on the excretions noted, the after period during which no alcohol is taken, the object being to control the fore period and to determine how long the effect of the alcohol lasted. In this experiment 70 cubic centimetres of absolute alcohol suitably diluted with water were used during the alcohol period.

RESULTS OF THE EXPERIMENT.

	Daily averages.		
	Total Nitrogen.	Ammonia.	Uric acid.
Fore period (7 days).....	13.25	.640	.635
Alcohol period (6 days)....	13.46	.678	.755
After period (4 days).....	13.65	.542	.615

The results show that during the alcohol period there is a different distribution of the nitrogen than normally as evidenced by the increase in ammonia and uric acid.

EXPERIMENT II.

The next experiment was carried out in the same manner, the only change being that 150 c.c. of whiskey, containing 45 per cent. alcohol, was substituted for dilute absolute alcohol. The diet was uniform throughout, but was not the same as used in the previous case, less purin constituents being present in the diet.

RESULTS.

	Nitrogen. Per cent.	Ammonia. Per cent.	Uric acid. Per cent.	Urea. Per cent.
Fore period (7 days) . .	15.61	.741	.554	89.6
Alcohol period (7 days) .	15.73	.873	.604	87.8
After period (5 days) .	16.53	.717	.572	90.8

The distribution of the nitrogen was changed by the alcohol as evidenced by the increase in ammonia and uric acid and the decrease in urea. The significance of these changes will be discussed later.

There has always been a strong belief that the injurious effect of alcoholic beverages was not so much to be ascribed to the alcohol therein contained as to other substances; the organic acids, extractive substances, etc., found in wines, for example. For this reason experiments were made in which nearly the same quantity of alcohol as used in the previous experiments, 70 c.c., was taken in the form of ale and port wine.

EXPERIMENTS III AND IV.

The average figures for two experiments are given here. We used 1050 c.c. of ale containing 8.44 per cent. by volume of alcohol during the alcohol period. In this and the following experiments uric acid was the only constituent of the urine isolated and determined. This substance is one of the most conspicuous and important of the nitrogenous excretion products, and its elaboration has been the subject of a vast deal of study.

RESULTS.

	Nitrogen.	Uric acid.
Fore period	13.09	.460
Alcohol period	13.52	.628
After period	13.15	.480

It will readily be noticed that the increase of uric acid is proportionally much greater in this case than when a purer form of alcohol is used.

EXPERIMENTS V, VI, AND VII.

Probably port wine has the reputation of being the worst form in which alcohol can be taken. Three experiments were made in which 500 c.c. of port wine containing 15.5 per cent. by volume of alcohol were added to the test diet during the alcohol period.

RESULTS.

	Nitrogen.	Uric acid.
Fore period	14.47	.559
Alcohol period	14.68	.722
After period	15.86	.582

There was a marked increase in the excretion of uric acid, but no more noticeable than with the ale.

These figures are the average of three experiments. Single days during the wine experiments

show a much larger increase in uric acid than was obtained by any other substance.

The results thus far given show that alcohol causes a disturbance of those processes which make up metabolism, and this disturbance is evidenced by changes in the distribution of the nitrogen among the several physiological constituents of the urine. It is obvious that if the question of the food value of alcohol was to be decided merely by the income and outgo of energy, or by its efficiency as a sparer of proteid, these experiments would afford little ground for conclusions. These experiments were planned to afford some clue to the toxic effect of alcohol, and in order to determine more accurately the time relations of the phenomena already observed, a series of experiments were made during which the urine was collected hourly during twelve to fourteen hours out of the twenty-four, the balance for the day being one lot, so that the total output for the twenty-four hours was obtained. In these experiments the subject had on the day previous a light supper containing no purin food, and no breakfast on the experimental day, so that the hourly output of uric acid fell to a nearly constant level by 10 a. m. of the experimental day. At twelve or one o'clock on this day a test meal was eaten; on the control days without, and on the alcohol days with the addition of known quantities of alcohol in a variety of forms, in most cases 25 to 30 c.c. of alcohol being taken after the meal. Such an experiment required two days to complete, one day being for control. A number of different subjects served in these trials, and with one exception the same result was found in all. The alcohol caused an increase in the excretion of uric acid; the point of greatest increase being during the fifth hour following the meal. This coincides with the point of highest, normal postprandial increase. The total excretion for the twenty-four hours of the alcohol day was larger than the control day, showing that the increase following the meal on the alcohol day was not due to a mere hastening of the normal output for a few hours to be followed later by a drop below the normal.

The matter of idiosyncrasy enters here as it does in most questions of metabolism. Some healthy persons have an unusually high output of uric acid on a diet containing very little purin food. Others are found who can scarcely be made to gain weight regardless of the character of the diet. In these experiments one subject was found who gave no increased excretion of uric acid, even after considerable quantities of

alcohol had been taken. This subject had the local reputation of being able to take without showing its effect a quantity of alcohol that would intoxicate most persons. I am unable to give any satisfactory reason why this subject should differ so markedly from the others. It seems to be a matter of personal idiosyncrasy.

In one of these hourly period experiments after the subject had fasted for nearly twenty-four hours and the hourly output of uric acid had attained a uniform condition, 50 c.c. of absolute alcohol diluted to 200 c.c. were taken without the usual accompanying test meal. The diuretic effect of the alcohol was marked; the hourly volume of urine increasing from a normal of 30 c.c. to 465 c.c. the first hour and 565 c.c. the second hour after the mixture was taken. This quantity of alcohol was sufficient under the circumstances to produce the characteristic narcotic effect, but there was no increase in uric acid output, which held a nearly uniform level throughout until the close of the experiment. Such a result indicates that an altered metabolism of the purin constituents of the food is responsible for the increase. It agrees well with one of the metabolism experiments (whiskey experiment) in which a small quantity of purin material was taken in the food and the percentage increase in the output of uric acid was small.

This experiment affords evidence also that urates are not swept out of the body fluids by diuresis. The volume of urine excreted during the first two hours following the administration of the alcohol, 1030 c.c., was as much as the total twenty-four hours' output for the subject under normal conditions, yet the uric acid excreted during these conditions, 56 milligrammes, was not quite as much as had been excreted during the two hours previous to taking the alcohol when the volume of urine was only one sixth as large.

The three excretion products considered in these experiments, urea, ammonia, and uric acid, are the most important end products arising from the proteid metabolism in the body. With all the experimental work which has been done upon the relationship which these substances bear to one another and to the metabolic processes by which they are elaborated, we still lack knowledge. The relation which uric acid bears to the complex compounds found in the cell nuclei, its origin from these compounds during the processes of metabolism and its partial destruction by oxidation in the body tissues, are matters established with a high degree of certainty.

The recent work which has been done on the physiology of this substance has emphasized the

importance of other organs than the liver in its preparation, but it seems probable that the liver is an agent of the greatest importance in dealing with the exogenous portion, a conclusion which harmonizes very well with the results which have been obtained in this work.

The final steps in the formation of urea are still obscure, but there is certainly good experimental evidence to show that its immediate precursors are ammonium compounds, and that the hepatic cells are the active agents in its preparation from these compounds. In pathological conditions affecting these cells a much greater proportion of the total nitrogen is likely to appear as ammonia.

It seems to the writer that the experimental results may best be explained by supposing that the alcohol has by its toxic action on the liver cells incapacitated them to some extent. The rapidity of its absorption into the portal circulation exposes the liver to a higher degree of concentration of the alcohol than other tissues of the body, excepting the stomach mucosa. A portion of the alcohol is probably oxidized immediately on reaching the liver, but there must be an appreciable time previous to its oxidation, during which it may exhibit its toxic action.

Certain facts indicate that the oxidative functions of the liver have suffered as a result of the alcohol. For instance, alcohol taken without food causes no increase in the excretion of uric acid and purin bases. Taken with food it causes an increase in the excretion of these substances, which with constant quantities of alcohol in the same subject seems to be roughly proportional to the amount of purin material taken in the food. In such conditions the percentage increase in the excretion of purin bases is the same as for the uric acid, and the point of highest increase coincides with the point of normal maximum output following a meal, viz., five hours. The exogenous purin material has not been so completely oxidized as normally. In those experiments where the ammonia was estimated it invariably showed an increase during the alcohol period, and since the diet was constant this also indicates liver incapacity.

The liver stands as a guard to prevent the entrance into the general circulation of various toxic substances arising from intestinal putrefaction or fermentation, or indeed from the ordinary processes of proteid metabolism. Some of this protective action we know depends upon the oxidation of the toxic substance and if alcohol impairs the oxidative powers in one direction, it is probable that it does in others as well. These

results, it must be remembered, have been obtained with moderate quantities of alcohol and no digestive disturbance was noted, but it is well known that larger quantities and the long continued use of moderate quantities do cause such disturbances. In such cases the trouble caused by the increased quantity of toxic material is aggravated by diminished ability to dispose of it.

Although it must be granted that alcohol yields its energy by oxidation in the body and may so far resemble the non-nitrogenous foods as to spare proteid under certain conditions, yet, in the opinion of the writer, these experiments demonstrate that it cannot properly be classed with fat and carbohydrate. Furthermore, I believe it is physiologically both unwise and incorrect to advise that the continued use of moderate quantities of alcohol is harmless. I have elsewhere expressed the opinion that alcohol, like salt water in a steam boiler, should be used only in emergencies, and recent criticisms have confirmed my belief in the fitness of the analogy.

414 EAST TWENTY-SIXTH STREET.

PROPHYLAXIS IN PREGNANCY AND LABOR.

By T. AVERY ROGERS, M. D.,

PLATTSBURGH, N. Y.

Many vicissitudes have occurred in the practice of medicine and surgery in past centuries. Persecution and even death have followed the searcher for medical knowledge. Comparatively few names of medical men have been handed down to our day from early times or the middle ages. The names of these few Immortals of medicine are preserved rather for greatness as philosophers and men, than on account of their greatness in the art of medicine. In fact, the science of medicine and surgery may be said to have had its birth in the eighteenth century. Education then became more general. Superstition was growing less. Sciences grew on a firm basis of reason and research. In medicine empiricism gave place to rationalism. Therapeutics received great assistance from chemistry. Human physiology and biology advanced hand in hand. Jenner at the end of the eighteenth century observed certain facts and followed them to their logical conclusions, applying in practice the great discovery of immunization as a preventive of disease. Anesthesia, asepsis, and serum therapy were among the great discoveries of the nineteenth century.

Surgery has made wonderful progress since Lister placed asepsis on a definite basis. Internal medicine has advanced rapidly. Diagnosis

has become easier and more certain, thanks to more perfect understanding of pathology, and the development of the many instrumental aids. The causes of disease have been investigated and become better known. These advances in the science and art of medicine have given supreme importance to the field of preventive medicine, which before had been of slight consequence. In obstetrics the great importance of prophylaxis must appeal to all who at any time practise it.

We all realize that puerperal infection can be prevented very much more easily than it can be cured. So it is in many other complications of the pregnant and puerperal conditions. Thousands of lives are yearly sacrificed because the obstetrician, either through criminal carelessness, thoughtlessness, or neglect, fails to comply with the simple rules of cleanliness.

From the beginning of pregnancy the patient should be under the observation of her physician. The urine should be examined monthly so that renal insufficiency if present may be early recognized and treatment instituted. The hygiene of the patient's surroundings is of the greatest importance. Fresh air both day and night with exercise in the open air is beneficial. Frequent warm bathing is necessary to maintain a healthy condition of the skin. Plain, nourishing diet is called for, and the occasional use of laxatives. During the last few weeks of pregnancy the breasts should be examined and retraction of the nipples or tenderness of the skin relieved by appropriate measures. An alcoholic wash of tannic acid is good to toughen the nipples. Such simple measures will conduce to the comfort of the mother.

Puerperal eclampsia is one of the most serious complications of pregnancy. Its cause has been a matter of some dispute. In the *Archiv für Gynäkologie*, Vol. LXXII, 1904, Zweifel gives his opinion of the cause of eclampsia, and its treatment in the wards of the Leipsic clinic. He believes its symptoms are due to a poison, probably an acid, circulating in the patient's blood and that the condition of the urine is due to an inefficient oxidation of albuminoid material in the system. He finds that the urea grows less and the albumin in the urine increases in an unfavorable case. Where the albumin decreases and the urea increases the case becomes more favorable. He believes the general practitioner should, in the presence of an eclamptic seizure, rupture the membranes at once and deliver as soon as possible. Dr. R. W. Lobenstine, of the Sloane Maternity Hospital, New York, in a study of fourteen cases reaches certain conclusions. These

are that in most cases of eclampsia an increase in the number of leucocytes is present and that this is favorable to recovery, providing the leucocytosis increases in as great a ratio as the toxicity. If the toxicity overcomes the leucocytosis the course of the disease is very unfavorable.

Sometimes a patient comes to us a few weeks or months before the expected confinement complaining of swelling of her feet or hands or puffiness of her eyelids or face. The first warning may be found in a low specific gravity of the urine or small quantity, with perhaps the presence of albumin. If albumin is found it is a most important danger signal and demands that energetic treatment be at once instituted. Examine the urine microscopically for the presence of casts which will indicate the condition of the kidneys. The diet of the patient in this condition of renal insufficiency should receive careful attention. Meat and eggs should be eaten sparingly if at all. Water should be drunk freely. If toward the end of pregnancy a milk diet should be established. Saline laxatives should be used, also hot baths that the system may be relieved of excrementitious matter, the products of metabolism, and the skin maintained in a healthy condition. Extra work must be removed from the kidneys as much as possible and the renal circulation stimulated.

Mrs. M. P., aged 24 years, in the eighth month of pregnancy, recently came to me with the following history: Four years before she had been attacked at the ninth month with puerperal eclampsia and for forty-eight hours had been unconscious and suffered at intervals of from ten minutes to half an hour from the most severe convulsions. In spite of energetic treatment her life was despaired of, but she finally recovered after intravenous saline infusions had apparently assisted nature in her fight against disease. When I saw her she had not profited much from her previous experience, and had not consulted any physician until she had progressed to a condition

of extreme renal insufficiency. She said she passed only four ounces of urine a day. It had a specific gravity of 1.004 and was loaded with albumin and granular casts. It became almost solid when boiled. Edema of the face, body, and extremities was extreme. She had great shortness of breath. She could not sleep well and had severe headaches. As only four weeks of her pregnancy remained prompt treatment was demanded to avert a recurrence of the previous disaster, eclampsia. She was placed on a milk diet. Daily hot baths were ordered with saline or other mild laxatives every day. She was urged to drink large quantities of water. A mixture of acetate of potassium 10 grains, and infusion of digitalis 2 drachms to the dose was given three times a day. The oedema gradually decreased. The urine increased in amount, as well as in specific gravity. In about three weeks the urine had a specific gravity of 1.020 and albumin was entirely absent. The patient in due time was delivered of a dead fœtus and made an uneventful recovery.

The frequency of eclampsia is given by the authorities as one case in 500 labors approximately. For some reason or other my own city of Plattsburgh and three surrounding country villages, representing in all a population of about eighteen thousand, have had, especially within the past four months, an extraordinary number of these cases. From September 15, 1904, to January 15, 1905, the births in this territory have been not over seventy-five. The physicians in the same area have reported eleven cases of puerperal eclampsia, two of which have proved fatal.

The detailed report of these eleven cases is herewith given. I should like to ask why this tremendous increase in the frequency of this disease in this vicinity, where for years eclampsia has been of quite common occurrence, judging from the records of the physicians. Is this disease possibly due to an infection? Do certain climatic conditions influence it? Is it not possible that the absence of frequent bathing among

Details of Eleven Cases of Eclampsia.

country people in cold weather has some influence in decreasing the excreting function of the skin and so throwing undue work on the kidneys and flooding the system with products which must be eliminated in large quantities in pregnancy to avoid toxæmia? The prevalence of this disease in this small section of country affords a fruitful field for an investigation into the predisposing causes so that its nature may be better understood and prophylactic measures applied in a greater degree than can be done at present. The people in this vicinity have not been sufficiently educated to the necessity of urinary examinations in pregnancy and other medical oversight. A change in this respect might decrease in a great measure the frequency of eclampsia.

It is stated that in Vienna eclampsia is unusually rare on account of the large quantity of tartrates of sodium and potassium which are present in the light wines generally drunk there. It is thought that these may combine with the bases in the food and prevent the formation of the poisonous acid in the blood.

Another serious condition of pregnancy where prophylaxis is of the utmost importance is in gonorrhœa of the pregnant woman. A neglect of proper precautions results in many cases in a tedious illness or rapid death of the mother, and often in blindness, which is worse than death, to the child. When this condition is discovered the patient should at once receive careful attention. Alkaline treatment will place the urine in good condition and local treatment to the seat of the disease in the vulva, vagina, urethra, or cervix will secure a healthy condition of the mucous membrane and destroy the gonococci lurking there. Daily hot antiseptic douches of mercury bichloride or carbolic acid solution will assist; also local applications of a one per cent. solution of silver nitrate, or of a two per cent. solution of silver albuminate. The frequent placing of a boroglyceride tampon or suppository is also beneficial.

A few months ago a young married man consulted me for treatment of an attack of gonorrhœa which he had contracted in forbidden paths. He also informed me that at about the time he first noticed the discharge he had intercourse with his wife, who was six months' pregnant. I informed him of the seriousness of the case and he had me institute treatment of his wife at once. She had already developed urethritis and vaginitis, which yielded nicely in the course of a few weeks' treatment, such as I have outlined. She was kept under observation until her confinement when she was delivered of a healthy child. On

birth the infant's eyes were treated after Credé's method, except that a one per cent. solution of silver nitrate was substituted for a two per cent. Many believe that this strength is equally efficient. A wash of boric acid was given the nurse to instill three times daily. No inflammation of the eyes resulted.

It is a safe precaution to use as a routine practice the instillation of a one per cent. silver nitrate solution after each delivery, as this results often in much benefit and can do no harm.

It is my habit to have a small tray ready in the lying-in room. In this is boiled water, some tape, and a pair of scissors to sever the umbilical cord. In the water has been dissolved boric acid. As the contents have been boiled the tape and scissors can be used for the cord when the warm boric acid solution remains for swabbing out the conjunctival sacs.

Gonorrhœal infection of the mother is no less dreadful in its results after delivery than it is in the case of the child in the absence of prophylactic measures. There exists a large raw surface in the uterus, besides excoriations of the vagina and perinæum. The gonococci thus find a ready entrance to the lymphatics. Some of the results are endometritis, salpingitis, peritonitis, and gonorrhœal arthritis. The victim stands a very good chance of becoming an invalid and undergoing tremendous suffering for lack of preventive treatment at the time it would be effectual.

Bacteria present in the secretions of the vagina have been found to be harmless in the absence of an infective disease, such as gonorrhœa. In these normal cases plain and antiseptic douches before labor are not advocated, but rather contraindicated, as they remove the protecting and lubricating mucous secretions normally found. The result is that excoriations of the mucous membrane are more liable to occur and autoinfection can more readily take place, as well as infection from unclean hands and instruments.

In conditions where a purulent discharge bathes the cervix and vaginal mucous membrane, whether it be gonorrhœal or not, the douche should be used frequently. Suspicious discharges should be examined microscopically after making a cover glass stain, and the presence or absence of gonococci established.

When entering the room of the woman in labor the physician should realize the tremendous responsibility which rests upon him. Two lives are intrusted to his keeping. The prospective mother lying in pain and helplessness trusts herself to him. The fate of her child also is in his

hands. How often this trust is basely betrayed! Certainly not with malicious intent. But none the less deadly is the criminal carelessness of many who attend a lying-in woman, and without any care, sometimes without even a hasty washing of the hands, go about their important work. The careful attention to the rudimentary rules of surgical cleanliness would save many lives.

If a nurse is in attendance she should scrub the patient's thighs, vulva, and anal region with hot water and soap, keeping up the mechanical cleansing for several minutes. Then the parts should be rinsed off with boiled water and afterwards with a one to one thousand solution of mercury bichloride. The preparation of the bed should be carefully supervised to see that all sheets and dressings are clean and freshly laundered. We are all familiar with the vicious habit in some families of placing an old piece of dirty quilt or carpet on the bed to come in contact with the mother and newly born child.

Puerperal infection, or child bed fever as it was called, was for two thousand years supposed to be due to suppression of the lochia. Later it was believed that the circulation of the milk in the blood was the cause.

In 1843 Dr. Oliver Wendell Holmes, that brilliant littérateur and distinguished physician, wrote a very powerful essay on Puerperal Fever as a Private Pestilence. He could claim the proud position of being one of the earliest physicians to recognize the true cause as an infection, and of pointing out the way to avoid this disease. Dr. Holmes had little scientific investigation on which to base his work, and yet he anticipated by many years the views of the profession. He struggled against many difficulties in his study of this subject and his position is very aptly expressed in a poetical way in the *Poet at the Breakfast Table*:

My life shall be a challenge, not a truce!
This is my homage to the mightier powers,
To ask my boldest questions, undismayed
By muttered threats that some hysteric sense
Of wrong or insult will convulse the throne
Where wisdom reigns supreme; and if I err,
They all must err who have to feel their way
As bats that fly at noon; for what are we
But creatures of the night, dragged forth by day
Who needs must stumble, and with stammering steps
Spell out their paths in syllables of pain?

Truly the path in the investigation of the cause of puerperal fever has been spelled out in syllables of pain for many thousands of poor suffering women.

In 1847, Semmelweis, of Vienna, after a large experience in the lying-in hospitals of that city,

stated that puerperal patients were chiefly attacked with puerperal fever when they had been examined by physicians who were fresh from contact with the poisons engendered by cadaveric decay. Ordinary washing of the hands afterward in plain water did not prevent the disease, but if, after washing the hands in soap and water, they were washed in a solution of chloride of lime the cases of puerperal fever were either absent or very rare. Here we find the first use of antiseptics in obstetrics. In 1850 James Y. Simpson published a paper on *The Analogy Between Puerperal and Surgical Fever*.

Dr. Rutson Mauray, after an investigation in New York city, found that one tenth of all the deaths in women during the child bearing period originated from diseases of childbirth. One half of these were due to puerperal sepsis.

Max Boehr states that one thirtieth of all married women of Prussia die in childbirth. The Puerperal Fever Commission of the Berlin Society of Obstetrics and Gynecology state that one tenth to one fifteenth of deaths of women from fifteen to forty-five years of age is due to puerperal infection. Women dying from this cause are taken away during the most useful period of their lives, and frequently leave children as well as a husband to mourn their loss.

All authorities now agree that the cause of this disease, in practically all cases, is surgical uncleanness. Probably infection from the hands of the physician is the most common cause. Other frequent causes are unclean instruments and dressings as well as infection from the patient's own body. Before making an examination of the patient the obstetrician should thoroughly scrub his hands with a hand brush and hot water and soap. This scrubbing should continue for three or four minutes, as the mechanical cleansing of the hands cannot be equaled by chemical disinfection, such as washing in bichloride solution. Particular attention should be given to the free borders of the nails. Soap and hot water wash away all oily and fatty material from the skin and dispose of bacteria which may be hidden away on the epithelial surface. After a thorough scrubbing of the hands, wrists, and arms they should be rinsed in pure boiled water, then in one to two thousand mercury bichloride solution or some equally good antiseptic. If the physician prefers, rubber gloves properly sterilized may be used on the hands. No precaution should be omitted in preparation of the field of operation, sterilization of hands, instruments, and dressings, as the outcome of these cases depends so largely on this preparedness.

The forceps should be used as a prophylactic measure in cases of unreasonable delay of labor; otherwise sloughing of the tissues may result.

In doing what he can to prevent laceration of the perinæum the physician can do much to lessen the after-effects which often send these patients to the gynecologist. Delivery of the patient on the side is probably best. Place a pillow between the knees. In this position the field of operation is under the eye of the surgeon. The head is controlled by one hand, the perinæum by the other. If any laceration of the perinæum occurs it should be carefully sewn up at once. Care should be taken not to overlook lacerations. Be sure the placenta is complete when delivered. If not, secure the remaining portion.

After the operation of delivery is finished carefully wash all the genital region with warm boiled water and afterward with a solution of mercury bichloride before placing a sterilized napkin in position.

This paper is presented not because it contains anything new, but because it will do us, as general practitioners, good to dwell on this subject of prophylaxis in pregnancy and labor. If it is the means of causing some one to pause and think, and so results in additional carefulness, some lives may be saved and the object of this paper will be accomplished.

Health in Connecticut During February, 1905.
—The following cases of infectious diseases have been reported to the Connecticut State Board of Health for the month of February: Measles, 180; scarlet fever, 120; diphtheria, 152; cerebrospinal meningitis, 14; whooping cough, 29; typhoid fever, 15; consumption, 42. The following is a list of towns whose health officers report that they have not been notified of any infectious diseases:

Andover, Ashford, Barkhamsted, Bethlehem, Bolton, Bridgewater, Brookfield, Brooklyn, Burlington, Canaan, Canterbury, Canton, Chaplin, Chatham, Cheshire, Clinton, Colchester (town and borough), Colebrook, Columbia, Cromwell, Danbury (city), Danbury (town), Danielson (borough), Durham, Eastford, East Haven, East Lyme, Easton, East Windsor, Enfield, Fairfield, Franklin, Griswold, Guilford, Hampton, Hebron, Huntington, Jewett City (borough), Killingworth, Lebanon, Ledyard, Lisbon, Litchfield (town and borough), Madison, Marlborough, Middlebury, Milford, Monroe, Montville, Morris, New Canaan (town and borough), New Hartford, Newington, Norfolk, North Branford, North Canaan, Orange, Oxford, Plainfield, Plainville, Pomfret, Portland, Prospect, Redding, Roxbury, Salem, Salisbury, Saybrook, Scotland, Shelton (borough), Sherman, Somers, Southbury, Stafford Springs (borough), Stamford, Sterling, Stonington, Suffield, Thomaston, Thompson, Union, Voluntown, Warren, Waterford, Watertown, Wethersfield, Wilton, Winchester, Windham, Windsor, Winsted (borough), Wolcott, Woodbridge, Woodbury, Woodstock.—Total, 95.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXVII.—How do you manage the alcohol habit? (Answers due not later than April 15, 1905.)

XXXVIII.—How would you prevent disease of the vermiform appendix? (Answers due not later than May 15, 1905.)

XXXIX.—How do you treat erysipelas of the face? (Answers due not later than June 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the NEW YORK MEDICAL JOURNAL AND PHILADELPHIA MEDICAL JOURNAL (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXVI has been awarded to Dr. Samuel Stalberg, of Philadelphia, whose article appeared on page 699.

PRIZE QUESTION NO. XXXVI.

THE DIET IN TYPHOID FEVER.

(Concluded from page 702.)

Dr. J. Preston Miller, of Washington, writes:

In the dietetics of typhoid fever three stages of the disease deserve consideration and different treatment in its thermic curves of abrupt acclivity, in early septic action to the summit of an undulating, prolonged plateau to a less abrupt defervescence declivity leading down to the level of the original plane, beyond which we often find a tail long strung out with many ups and downs. Each of the three directions of this line has significance as to kinds of diet. The age of the patient comes in for separate consideration as to character and amount of diet, and is quite as important as the stage of the disease. Temperament should be noticed, for the plump and plethoric should not be fed the same as the lean and skinny.

In the first decade of life the disease is infrequent and mild; under five years it is rare; and under two, good clinicians have failed to find it and believed it does not exist; but in severe epidemics it may be found at any age. Children

with typhoid have constipation in about two thirds of all cases, while in the adult this ratio is reversed and diarrhoea exists in about two thirds. Water, so important in typhoid, must be given warm or hot to the very young, but may be given ice cold to the adult. Milk is borne better by children and is more essential to them; starchy food we know a child under eight months cannot digest.

The child at the breast should have one grain of sodium bicarbonate and two grains of pancreatin given with each nursing if the stools are full of curds. If the curds remain large, ten drops of essence of pepsin may be given, with or without this powder, and hot water between nursings, with a bit of common salt in the water. If constipated, chicken tea may replace the water, and if curds then still remain I take the child from the mother's breast and give it peptonized milk, regulating the percentage of cream to suit the bowel conditions. A child of five will take chicken tea in addition to peptonized milk, and I give cold water at three years, later increasing the ratio to other food each year up to puberty. Kumyss or Matzoon can be given at any age that the child will take it. At six and eight years children will take chicken tea in preference to all meat broths. At eight years and later, when I give chicken tea it is prepared by breaking the bones by pounding with a hammer to expose the marrow, after the meat has been cut clean from the bone, the chicken having been cleft in halves from neck to tail. The meat chopped fine is added to the pounded bones of one half the chicken. This is put into a vessel with a tightly fitting lid containing three pints of cold water, brought gradually to a gentle boil, and kept constantly hot on the stove and fed as needed, after straining. It must be well salted. While this is a favorite food with children, it is from four to six times as rich in food products as ordinary chicken tea and is that much more valuable for a patient at any age.

The beginning of the second decade is the same as the last two years of the first. But when within one year of puberty and about five years after its beginning we are in that period of life to which typhoid is most fatal; the mushroomlike growth necessary to the rounding out of limbs and filling out the adult form of the body brings about a glandular development, especially of the lymphatics, which renders the system peculiarly vulnerable to sepsis. Peyer's patches, all the lymphatic glands, the mesenteric glands, and the lymphatics everywhere along the line of intestines aid the toxins of typhoid in their initial field. In the septic stage, especially in the plump youth,

metabolic disturbance is so profound that rapid tissue waste seeking sewerage through the lymphatics so thickens the fluid that this alone would render its flow sluggish, but the enlarged glands further obstruct this circulation; the thinner part of the fluid squeezes through the obstruction, the thicker remaining to distend vessels and plague the tissues, the stasis thus lending itself to a more perfect culture medium for the toxic process. We can produce further havoc here by the ingestion of proteids, carbohydrates, etc., rendering this septic fluid yet more mucilaginous and difficult of flow. If we recall the function of the lymphatics, that it is to remove effete matter from the tissues and also to take up superabundance of nutritive fluids not immediately appropriated to tissue building, holding the same in reserve, it will enable us to see wisdom in the epistaxis, or diarrhoea, or both, so frequent in the plump youth in the initial stage. Nature here understands her business and gives us anorexia. In no other fever is this so constant a symptom in the early stage. Rich foods are not needed in the first few days, and cold water is as much needed as it is craved. It may be objected that water is not a food, and therefore I deem it proper to give my reasons for using it almost to the exclusion of other foods if called to a typhoid patient in the stage of thermic acclivity. In the condition of lymphatics above described, water is not only food, it is diluent, eliminant, and antiseptic. Water, in small quantities, has definite effects on the cardiovascular system; cold water diminishes the pulse rate and increases the blood pressure, while hot water raises the pulse rate and lowers the blood pressure, the effect ceasing in about twenty-five minutes. Moreover, we know that in other conditions, such as the removal of calculi, patients have been put to bed and given absolutely nothing but water, a goblet every hour, for ten days without complaint of hunger or other inconvenience.

To plethoric patients I have given two ounces of cold water every twenty or thirty minutes for two or three days, replacing this with albumin water during eight hours of the night, giving an ounce to the hour, with the result that the dazed eye became clear, muttering ceased, and the stupor disappeared. To albumin water I add lemon juice or orange juice pressed from the fresh fruit to obviate the objection urged that it increases the difficulty of keeping the mouth clean. If called early, while the temperature is going upward rapidly, giving water freely, and avoiding proteids, carbohydrates, etc., in any considerable quantity, is the most important by far in the dietary at that stage, especially in young, plethoric patients.

All food in typhoid fever must be fluid for the first few weeks of the disease, and until the temperature has touched normal. The quantity for adults, with variations for reason, should be about eighty ounces in twenty-four hours. Albumin water, in the strength of white of fresh egg one part, water two parts, salt or fruit juice added, should be the only additional food during the period of acclivity in the thermic curve. On the fourth day of the septic stage I give peptonized milk if I ordered the dieting the previous days. If I am called at the acme of fever, when untreated milk, egg nog, carbohydrates, etc., have been given and of course passed through the stomach only partly digested, fermented particles and curds now producing intestinal havoc, tympanites, pyrexia, etc., I do not give milk, even if peptonized. If this occurs after the middle of the second week, there is danger of intestinal hæmorrhage, and if another week later it would greatly endanger the gravest accident of typhoid fever—perforation. If there are grave nervous symptoms, I give liquid food that will remain liquid throughout the gastrointestinal canal, matzoon or whey. The latter in albumin water is a good vehicle for brandy or whiskey, and may be given freely. When these grave nervous symptoms disappear, the stools are of good consistence, and the abdomen is soft, I give peptonized milk.

Milk is theoretically the paragon of food in typhoid cases at any age, containing the ideal combination of proteids, fats, carbohydrates, and salts in liquid form. But we may well bear in mind that milk is solidified before it can be digested. Moreover, there are many persons who cannot digest milk even in health or who cannot take it ten days without serious biliousness. Such persons will assimilate milk less well in the febrile state and are apt to have increased sepsis, meteorism, and the complications of swollen gums, thrombophlebitis, furunculosis, neuritis, etc. Milk in the natural state will produce curds in the stools, which are dangerous to swollen and ulcerated Peyer's patches, and particles of curds become buried in the folds of the intestines, affording a nidus for germs. But the scorbutic condition can be averted by the use of orange juice and lemon juice; thrombophlebitis by the copious use of clear cold water; neuritis by assisting digestion, and from personal experience I know how quickly curds disappear when milk is not given in any form until it is peptonized. *I permit no milk to be given, except peptonized, in typhoid cases at any age of the patient or stage of the disease, including that given in cocoa, coffee, tea, and other drinks. Matzoon, kumyss, and whey, are not included in this.*

Thus prepared, I give milk after the acclivity and during the prolonged undulating high plane—the plateau—of the fever chart, so long as there is no hæmorrhage of bowels, no curds, and tympanites is not extreme. I permit four, and insist on not less than three, ounces every two hours for sixteen hours and water two to four times between each portion of milk. In the eight hours of night sleep after ten p. m. I give albumin water, and when the heart's action is good and strong I add water to the albumin water, or give it separately at the same awakening, and permit the patient to sleep two or three hours between drinks. In asthenic patients I give water or food every hour, including brandy at alternate doses. Where there are serious nervous disturbances I increase the quantity of brandy and lengthen the intervals night and day, and I replace milk with whey. When intestinal hæmorrhage occurs, I permit no food from which débris could possibly pass through the stomach down into the bowels and excite peristaltic action or irritate the ulcerated mucous surface. I personally examine the stools not later than the middle of the second week for clots of blood even if hæmorrhage is not reported. If blood is found in any form, I give fresh beef juice. The fresh juice is best prepared by taking one third of a pound of round steak, nearly two inches thick, with the surface slightly broiled, simply to give it flavor, and pressing out the juice with a meat press or lemon squeezer into a small cup set in hot water. Flavor abundantly with salt, slightly with pepper, and feed it to the patient from a heated cup. It must not be hot enough to thicken the albumin in the meat juice or cold enough to become flat in taste. If it is permitted to congeal, from cold, the patient will not take it. From one and a half to two ounces of juice should be given, and this should be repeated three times a day, also about two pints of water in small quantities. This food should be continued six to seven days. Then barley water, containing carbohydrates, now much needed, may be given, and acidulated albumin water in lieu of beef juice, and when there is diarrhœa with no great amount of tympanites I prefer these to ordinary water in any stage after the acclivity.

In the third or fourth week, when defervescence begins, any of the foods mentioned may be given that patient may prefer when symptoms already indicated do not forbid. Artificial waters, forbidden in the early stage because of the excess of carbon dioxide, are now permissible and grateful to the patient, also an excellent vehicle for brandy, peptonized milk, and some of the fluid meats. Matzoon is especially valuable now if there is diarrhœa. As we get well down the line

of declivity, unless there is much tympany, I begin the use of mucilaginous foods, oatmeal *strained*, arrowroot, tapioca, etc. As soon as the normal plane is reached I give semi-solids, and the first of these will be a fresh egg boiled one minute, or poached equally soft, on dry toast or sparingly buttered if the butter is fresh. This done in early morning, if well borne is repeated at five p. m., and again the next morning, and followed at noon with scraped beef. *From the time the first egg on toast is given every meal as outlined above is immediately followed with a full dose of pepsin.*

There is a class of cases, fewer before maturity, called relapsing, deserving of special mention in the dietary. In these the temperature, after becoming normal or nearly so, will run up again, not usually very high, but persists in remaining uncomfortably above the normal, running a more or less erratic course. This is the tail to the deferrescent thermic line before referred to. In some of these lingering cases, much to be dreaded, the patients are profoundly asthenic, the temperature running low, 100° to 101° F., and loss of weight may exceed a pound a day, emaciation becoming extreme. In either of these classes I pay less attention to the temperature chart than to the gastrointestinal tract. I begin by suspecting curds of milk, and if they are found, even in small particles, I forbid milk absolutely in every form. In tympanites carbohydrates are often the cause. A dry tongue is a call for acids, fruit juice, and sodium chloride. The asthenic, when their condition is not due to diarrhea or indigestion, will do well on stimulants, black coffee, champagne, or very old port, if not too sweet. If the tongue is fairly clean, tympanites absent or slight, I should soon give junket and presently add to the list baked custard followed with pepsin and orange juice over milk sugar. If bowel distention follows, beef juice should be given for twenty-four hours, then dry toast and soft egg followed by pepsin, scraped beef or toast, and other food as before outlined with this class of food. Any patient with low, lingering fever after twenty-eight days, and sometimes after twenty-four days of the disease, is given such semisolid food as I have described when the tongue is moist and fairly clean, the abdomen soft, the stools nearly normal in smoothness, giving also mutton or beef broth, but chicken broth only when the stools are inclined to hardness. I should give gelatin food in the opposite condition—wine jelly, blanc mange, farina, boiled rice with beef juice, baked custard, junket, etc., giving these as an addition to the list when toast and soft egg are first given.

In the third decade typhoid, though less fatal than in the second, is yet very severe, each decade growing lighter until nearly sixty years is reached, when the disease becomes grave. Men especially fare badly after sixty with this disease. Alcohol, rarely given in the first decade and yet sparingly in the second, is gradually increased until about sixty years of age, when I give it more frequently. As to the form in which I administer it; brandy (French or California) or rye whiskey not less than five and preferably ten years old is given in the early stage. I prefer champagne or very old port, not very sweet, during deferrescence.

Dr. G. N. Murphy, of Paducah, Ky., writes:

As soon as I see a case of typhoid fever, I select a liquid diet that is easy to digest, that will leave the smallest amount of solid matter to form fæces. The selection is always made with due regard to any whims or idiosyncrasies of the patient as far as is consistent. Sweet milk with one fourth part of limewater, is the diet of choice if there is no valid objection against its use. This is given every four hours, and from three to six ounces are allowed at each feeding. The stools are carefully examined each day for milk curd, and if it is detected in any considerable quantity, the milk is predigested by peptonizing, and to prevent the patient from tiring of this restricted diet a change is frequently made to whey and buttermilk. Some patients reject a milk diet of any kind at the beginning, while others take it kindly at first but rebel against it later. In such cases a change is made to animal broths and extracts. Whiskey and brandy are also valuable adjuncts to the supportive treatment of typhoid fever, and in asthenic cases, where the vitality of the patient is at a low ebb, as is shown by a high temperature, rapid, weak pulse, low muttering delirium, etc., I administer these stimulants boldly, giving from six to twelve ounces during twenty-four hours to an adult and a proportionate quantity to children, according to age. Ice water, plain or as lemonade, is allowed from the beginning to the termination of the disease as frequently and in as liberal quantity as the patient desires. After convalescence is established I still advise the use of a liquid diet for a period of two weeks to prevent the possibility of solid particles of undigested food or hardened fæces doing violence to some delicate ulcerated surface of unhealed bowel.

In a general practice of fifteen years I have treated many cases of typhoid fever, and in the main have adhered to this dietary without cause to regret my course.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 704.)

Fercao is an iron-cacao dietetic preparation, which the makers state is prepared from pure cacao and iron saccharate.

Fermangol is an iron manganate preparation, which, according to the maker, contains 0.5 per cent. iron and 0.1 per cent. manganese, with glycerophosphoric acid, sugar, aromatics, etc.

Ferrocotin is the name given to a peptonized guaiacol-iron-albuminate combined with thymol in syrup, which is recommended for use in the treatment of scrofula, incipient tuberculosis, bronchial catarrh, etc.

Fibrolysin is a chemical combination of one molecule of thiosinamine and a half molecule of sodium salicylate. It forms a white, crystalline powder, which is readily soluble in cold and warm water. The solution is affected by light and air, and must be kept in small amber colored containers. It is administered hypodermically in all cases in which thiosinamine is used.

Fluinol, known previously as fluorinol, is an alcoholic fluid extract of fir and pine needles to which volatile oils have been added. It is recommended as an addition to baths, gargles, and sprays.

Formosapol is a saponified cresol compound, with a composition similar to lysoform.

Galbanic Acid, a substance extracted from Galbanum by Hirschsohn, has been studied by von Kuelenstierna (*Archiv für Pharmazie*, 1904, page 536). It crystallizes from dilute alcohol in magnificent long colorless needles, devoid of odor and taste, and melting at 155 to 156 degrees. Alcoholic solutions are very slightly acid to litmus paper.

Gelasepsin is a 1 to 2 per cent. sterilized solution of gelatin prepared with physiological salt solution.

Glidin, also known as Dr. Klopfer's wheat albumin, is a compound of albumin, salts, and lecithin, forming a fine yellowish powder free from odor or taste. It contains no nucleins, and the production of uric acid in the system is accordingly lessened. It swells in contact with water, and is recommended for the baking of bread intended for sufferers from diabetes and kidney diseases.

Goudrogenin is a dry preparation of pine tree tar, which appears on the market in the form of brown scales, which are readily soluble in water. The solution is said to possess all the properties of tar water and to possess strong antiseptic properties.

Graminin is a dry form of hay fever serum, which is intended for use as a snuff in the treatment of hay fever.

Griserin is loretin combined with sodium carbonate 4.25 per cent. or sodium bicarbonate 6.75 per cent.

Guaiacacodyl is another name for guaiacol cacodylate.

Guaiacolin is one of the lengthening list of sulphoguaiacol syrups.

Guaialin is a benzoic acid methylene diguaiacol ester, forming an amorphous, greenish gray powder, which is used in the same indications as guaiacol.

Guaiaresin is a compound of guaiacol and arsenous oxide.

Guaiaresin syrup contains in each 10 gm. 0.005 gm. of arsenous oxide and 0.2 gm. of guaiacol in combination with calcium chlorohydrophosphate and cinnamic acid.

Guatannin (guaiacoltannocinnamate) is a product of a Berlin chemical laboratory, the uses of which will be obvious from its chemical name.

Gymnostachyum febrifugum is the name of a root that is used medicinally in India, according to David Hooper. The root is boiled and given to women with garlic or pepper after their confinement. It is also used in cases of fever and bilious complaints. The rhizomes are brown in color, and from 1¼ to 2 inches long and ⅜ inch in diameter. They have a bitter, woody taste. A cross section shows a brown, almost reddish, outer skin, a thick, dark rind and a light colored wood, with hollow centre. The active principles are contained in the bark. The bitter principle is of an acid resinous nature, and is soluble in alcohol, ether, and water; its solution is colored yellow by alkalis. Cholesterin was present, but no alkaloids were found in the bark.

Herniarin, an Active Principle of Herniara Glabra, has been obtained in a pure form by Grein (*Pharmazeutische Zeitung*, 1904, page 258). Herniarin is easily soluble in absolute alcohol, and not at all soluble in ether. When triturated with sulphuric acid the crystals turn yellow, later pink, and finally dark red. On boiling with water the product is split into glucose and herniatic acid. This acid is regarded by Grein as the active principle of the herb *Herniara glabra*, which is used in the treatment of stone in the kidney, Bright's disease, etc., chiefly as a diuretic.

A Modification of Todd's Mixture for the Treatment of Grippe.—The following, according to *Répertoire de pharmacie*, for March 10, 1905, is a very agreeable modification of Todd's mixture, a preparation esteemed in France for the treatment of grippe:

R	Tincture of canella.....	5 parts;
	Infusion of Ceylon tea.....	75 parts;
	Syrup of lemon.....	75 parts;
	Jamaica rum.....	40 parts.

M.

This mixture is used not only in cases where it is desired to secure a tonic effect, but it is said to act on the kidneys in cases of grippe and lithiasis. The tea is an excellent diuretic, producing increased cardiovascular activity. On account of the theine and the theophylline it contains, it is an excellent stimulant in the cardiac adynamia so frequently observed in cases of exhaustion after the fiftieth year. The syrup of lemon is an excellent corrigent, being agreeable to the taste, and acts at the same time as an antiseptic and a diuretic.

SLEEP AS AFFECTING RESPONSIBILITY.

It is a matter of common knowledge that both natural sleep, with its occasionally attendant somnambulism, and the allied conditions produced by hypnotism or the action of some drug do at times so impair the interpretation of one's sensory or illusory impressions as to lead to the most regrettable acts. The subject is of such interest in its bearing upon the question of responsibility that it has over and over again been dealt with by writers on forensic medicine. It has recently been considered anew in a Paris thesis by V. J. Leconte, a summary of which we find in the *Revue française de médecine et de chirurgie* for March 27th.

During the process of going to sleep, says M. Leconte, and during the gradual waking the senses of sight and hearing often give rise to illusions, and he gives a number of examples of their having led to tragic acts. A man in the process of waking, cited by Hofbauer, thought he saw a motionless spectre in his room, and struck at it with a weapon; the victim's groans roused him to full consciousness, and he found that he had killed his wife. In like manner a man sleeping in a room with others fancied he saw a wolf, and killed one of his companions, and a soldier, roused suddenly by something that he took for an alarm, wounded several of his comrades.

It is not always an immediate act that is the fruit of an illusory sensation perceived during sleep. A healthy man, it is true, puts away from him the remembrance of a dream, but he who is morbid and perhaps already on the verge of insanity cherishes it and broods over it till he comes to put faith in it as a truthful memory, and at some future time takes tragic revenge for a purely imaginary injury. There have indeed been occasions when a sane man could not with safety recount certain of his dreams, as when Cæsar had a man executed for having dreamed that he had murdered him (Cæsar), holding that the dream revealed the man's real intention.

We cannot of course justly hold a man morally responsible for an unlawful act committed under the influence of impaired or perverted consciousness, but necessarily it is not always easy to establish the fact of the impairment or perversion, and, as M. Leconte points out, we must hold a known somnambulist responsible if he fails to take measures to guard against the possible consequences of his peculiarity.

TYPHOID PERITONITIS WITHOUT PERFORATION.

There are on record a number of cases in which signs of general peritonitis have been observed in the course of typhoid fever, coming on suddenly and naturally leading to a diagnosis of intestinal perforation, but in which, on operative intervention or post mortem examination, no perforation was found. Such an instance is reported by Courtois-Suffit and Beaufumé in the *Bulletins et mémoires de la Société médicale des hôpitaux de Paris* for March 23rd. Though the onset of peritonitis in this case was fulminant, occurring on the twenty-first day of the fever, the lesions found indicated that the peritoneal inflammation must have existed for a considerable time and pursued a latent course. The fatal termination took place within twenty-four hours of the outburst of the symptoms attributed to perforation, but not until after laparotomy had been performed. Neither during the operation nor at the examination after death did the most minute exploration disclose either intestinal perforation or the fact that from any organ there had escaped material capable of

setting up peritonitis. A noteworthy feature of the case was the entire absence of tympanitis.

The authors, discussing the pathogeny of these cases, are inclined to treat Dieulafoy's theory of independent typhoid infection of the peritonæum as only an hypothesis resting on nothing more substantial than analogy. They suggest that in their own case the peritoneal inflammation was more probably propagated from the intestine by contiguity, since it was decidedly most marked in the peritoneal coat of those portions of the intestine that showed the most pronounced lesions of Peyer's patches; and contiguity does indeed seem sufficient to account for the peritonitis.

"SPERMATORRHŒA."

Strictly speaking, this bugbear of the victims of the advertising quacks who treat "diseases of men" has no existence. That is to say, there is no morbid condition that is correctly denoted by the word "spermatorrhœa," for the term would be applicable only to an almost constant flow of semen from the urethra, and there is no such condition, as is ably pointed out by Dr. Rochet in *Lyon médical* for March 5th. It is altogether probable that the quacks endeavor, and with too much success, to impress their victims with the idea that any involuntary discharge of semen is significant of a disease that they choose to term "spermatorrhœa" or "seminal weakness," whereas we all know that the occasional lascivious dream that culminates in an ejaculation of semen is strictly physiological. It is true that a man who has had gonorrhœa, and supposes himself cured, may lose a drop or two of glairy fluid from the urethra after micturition. It is also true that a like fluid, so far as gross characteristics are concerned, may be pressed out from the prostate during defæcation and escape from the meatus urinarius. But in neither case is it seminal fluid that is lost. Semen never dribbles; it is forced out by ejaculation.

But there is such a thing as the irritable urethra, among the symptoms of which may be undue frequency of involuntary emissions, ejaculations on slight material or emotional excitement of the genitals, and premature discharge of the seminal fluid during coitus. For lack of a better and well known name, we may conveniently speak of this

condition as "spermatorrhœa." M. Rochet properly insists that it is not a pathological entity, but may be dependent on various local diseased conditions or on any one of a number of morbid states of the nervous system. It may often be cured, but only by doing away with the particular cause on which it depends. Its treatment, therefore, requires all the resources of the skilled physician, and it is not to be overcome by any nostrum.

THE TRAUMATIC NEUROSES IN AND OUT OF COURT.

Were it not for the damage suits associated with the traumatic neuroses, the latter would not receive the consideration that they now do as a unique form of clinical phenomena. Every effort to establish cerebrospinal concussion as a distinct and separate disease entity has signally failed, and the attempt to do so is now practically limited to the environments of the court room. Here it will probably continue to be made so long as the pathology of these troubles remains a matter of hypothesis and logical deduction; for in a debatable field two opposing interests are struggling for supremacy and personal gain. The object of one side is to magnify and sharply differentiate the results of railway and other accidents; that of the other side is to belittle and deny the existence of those alleged results. As a matter of fact, these accidents have not been found to produce any form of functional or organic disease that the science of medicine has not long been familiar with. These accidents do provoke vascular and sclerotic changes of all kinds and functional disturbances of various degrees, but the pathology of these troubles and their symptomatology, when sufficiently marked to be detected, are in no sense different from the pathology and symptomatology of the same troubles when provoked by other than traumatic causes.

The traumatic psychoneuroses are to-day recognized to be nothing but hysteria, neurasthenia, and hysteroneurasthenia. Outside of the court room one hears now very little discussion of these traumatic neuroses, and in the textbooks there is absolutely no need of a special chapter upon them except for the discussion of their medicolegal aspect. Aside from the clash of personal interests involved in their consideration in the court room, there are

two influential factors that tend to keep up this medicolegal debate in regard to the traumatic neuroses. One is the court's insistence upon exact physical evidence; the other is the natural preconception, previous training, and dominant conservatism of the legal mind. Under these circumstances, mere opinion, especially when it is new and based upon hypothetical deductions, however expert it may be, is placed at a great disadvantage and usually at its lowest value. This is unfortunate, but under the present system will probably continue to be irremediable.

If every bit of scientific evidence could be made to correspond with the exactness and physical demonstration that ordinary evidence is made to exhibit, scientific expert testimony would not be held in the insignificant light that it too often is now; but one wonders what would become of the law of gravitation, the undulatory theory of light, the atomic theory, the nebular hypothesis, and other great and accepted scientific generalizations in view of such a demand for exact physical evidence. All human knowledge is relative. From the exact facts of mathematics all the way down to the silliest bit of gossip, the evidence rests upon the integrity and reliability of the five senses. Every tyro in physiology, however, knows what that means. And yet, strange to say, the court denominates some of the evidence afforded by these unstable and unreliable senses as exact and other evidence afforded by them as inexact. Five witnesses to a murder are credited with giving exact information; the testimony of five experts in astronomy who declare for the existence of the law of gravitation is looked upon as not sufficiently exact for the ends of justice. The whole scientific world may be united in their opinion of the nature of hysteria, but their testimony in court does not have the weight that the testimony of perhaps an excited and ignorant witness of a burglary has. This is extraordinary, but is probably necessary and inevitable in a system based upon trial by jury. A jury can understand what it is to view a burglary or a murder, even though the witness may have been most excited and his senses most unreliable, but it cannot understand why an hysteric may be blind, anæsthetic, and paralyzed, and yet recover in the twinkling of an eye. On account of his own ignorance and mental incapacity,

the average jurymen projects his shortcomings over on to the witness and regards the lay witness as the possessor of exact knowledge and the scientific expert as the holder of inexact knowledge. Scientific facts directly demonstrable through the five senses do not usually appeal so strongly to the average jurymen as do the demonstrations of the ordinary, commonplace doings of mankind. How much less, then, do the proofs and demonstrations that are based upon logical deductions, hypotheses, and mere opinions appeal to him!

In every case of a person seeking damages for injury the first thing that has to be determined in court is the presence or absence of malingering. The detection of this is sometimes a most difficult matter. The medical expert can often assist in unmasking the clinical simulations, but the detection of simulation is in general a police rather than a medical problem.

Malingering having been excluded from consideration in the case, the nature of the plaintiff's trouble, its ætiology, and its prognosis become purely a matter for the science of medicine to determine. These having been established, it falls to the court, again, to decide the amount of damages such medical testimony should bring to the plaintiff. Thus it is seen that in connection with the traumatic neuroses there are always two distinct and sharply defined lines of investigation—the civil questions of fraud and damages on the one hand and the medical questions of the nature of the plaintiff's trouble on the other. If the court would forbid the mixing up of these two well defined lines of testimony by the opposing counsel, much of the confusion and wrangling over the traumatic neuroses would be abolished.

It goes without saying that an expert commission of medical men is the most proficient to decide the medical character of the case, and that the average jury as now constituted is the least proficient. So true is this, though it is not often so frankly admitted, that the counsel usually employ their best efforts to avoid the full force of such expert opinion by all sorts of forensic tricks and subterfuges in order to keep the final decision of the question wholly in the hands of the uninformed jury. The lawyers put upon the stand nominal and unreliable experts who are expected to take a partisan view;

they pick all kinds of irrelevant flaws in the opposing expert testimony; they struggle to confuse and embarrass the jury in every possible way upon the abstruse scientific questions. One side is not less guilty than the other in this respect, for they both resort to the same tactics when they fear they are losing ground in the eyes of the jury. Even in cases where there is an honest attempt to get at the truth, the moment the balance of favor leans to one side or the other, the losing side instinctively resorts to the usual forensic tactics. In a word, the system is vicious, because it subjects scientific facts and generalizations to debate between two unscientifically prepared opponents, the merits of the debate to be ultimately decided by a still less scientifically prepared body of laymen. The whole trial thus becomes largely, from the medical point of view, a duel of wits before a most unsophisticated body of intelligences. So remote is such a course from the true scientific method of investigation that it is no wonder the system is the source of laughter and disgust to the scientific world. While expert testimony under the present system receives but scant honor in court, the scientific world balances the loss by the amusement which so childish, antiquated, and absurdly unscientific a method of getting at truth affords it.

The legal training is toward conservatism, the scientific toward radicalism. The former is such as to incline its recipient to exaggerate the value of precedent, retrospection, and authority; the latter is such as almost to force one to doubt mere precedent and authority and to look forward constantly to newer ideas and more recent discoveries. Here lurks the secret of the frequent clashes honestly provoked in the court room between the counsel and expert witnesses. Again, the untrained jurymen, both by instinct and to a certain extent by the instruction of the court, is led to look askance upon all evidence that he himself cannot comprehend or perceive directly through his five senses.

Upon all these accounts, it is amazing that expert testimony holds its own as well as it does in our law courts. It speaks volumes for the intrinsic value of such testimony. Until scientific data, directly or indirectly demonstrable and accepted as such the world over, are recognized in our law courts in the way that they are outside of the courts, and are presented and passed upon there

by those whose knowledge and special training render them the most capable of presenting and passing upon them—in a word, until the court room ceases to be an arena of debate and play of wits or a school of instruction upon great and abstruse scientific questions in the presence of and for the final decision of an ignorant and wholly unprepared and confused panel of jurymen, I see no likelihood of improvement in the management of expert testimony or of a cessation of the undignified and useless disputes that now so often rage around the traumatic psychoneuroses.

A traumatic neurosis in court is something more than a traumatic neurosis out of court, not, however, by reason of its medical characteristics. It is hysteria or neurasthenia merely with a damage suit attached to it and all that the latter involves in the way of legal bias, partisan debate, and the instruction of an unscientific body of laymen. It is the latter elements, the legal complications, that are responsible for the unseemly displays that sometimes attend the discussion of these troubles. The dignity of medicine and the positiveness of its knowledge are not disturbed by the legal battles which a vicious system in our law courts allows. The disgrace of expert testimony as it is now engaged rests entirely upon the legal fraternity and their antiquated methods. The nature of the traumatic neuroses has long been explained by the science of medicine. L. HARRISON METTLER.

THE PHYSICIAN IN RECENT FICTION.

What has become of the doctor in this year's fiction? A year ago scarcely a week passed that we did not feel called upon to draw attention to some clever tale either written by a physician or in which a physician was either the hero or the *deus ex machina*. Lawyers and burglars seem to hold the centre of the stage at present; perhaps the doctor is waiting in the wings, preparing for a triumphant reentrance. We are ready to applaud vigorously.

THE X RAY IN THE TREATMENT OF PYORRHOEA ALVEOLARIS.

Our dental friends seem to have met with some success in treating pyorrhœa alveolaris, a very serious affection, by means of the Röntgen ray. The most recent communication on the subject that has come to our notice is by Dr. Elizabeth C. Fields, of Lincoln, Nebraska, published in the

Dental Digest for February. Dr. Fields remarks that her attention was called to the matter by an article by a Dr. Price, published in some dental journal. She reports a case of apparent cure of the disease by means of the rays. She expresses some doubt as to the permanence of the cure, but adds: "Still, there is much to commend this method if it is even as satisfactory as the old, for it is absolutely painless and much easier than the mechanical."

THE EPIDEMIC OF CEREBROSPINAL MENINGITIS.

There are indications that the prevalence of epidemic cerebrospinal meningitis in New York is on the decline, and the indications may properly be interpreted at quite their apparent worth in view of the undoubted tendency to look upon various cases of brief and fatal illness in children as examples of the disease in question without a very searching inquiry into their real nature.

THE LONG ISLAND COLLEGE HOSPITAL.

We are glad to see that this school, one that for many years has stood high in the esteem of the profession, is taking pains to make Spanish-speaking students welcome. It has issued a circular printed in the Spanish language, and we do not doubt that many students from the West Indies and South America will be attracted to the Brooklyn school.

News Items

Society Meetings for the Coming Week:

MONDAY, April 17th.—New York Academy of Medicine (Section in Ophthalmology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, April 18th.—New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, April 19th.—New York Society of Dermatology and Genitourinary Surgery (private); New York Academy of Medicine (Section in Genitourinary Diseases); Woman's Medical Association (New York Academy of Medicine); Medicolegal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, April 20th.—New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, April 21st.—New York Academy of Medicine (Section in Orthopaedic Surgery); New York East Side Physicians' Association; Manhattan Medical and Surgical Society (private); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

SATURDAY, April 22nd.—New York Medical and Surgical Society (private); Harvard Medical Society, New York (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending April 8, 1905:

	April 8.		April 1.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	422	13	470	21
Diphtheria and croup	339	27	317	31
Scarlet fever	250	7	224	20
Smallpox	4	..	1	..
Chickenpox	94	..	149	..
Tuberculosis	441	201	413	172
Typhoid fever	26	13	45	6
Cerebrospinal meningitis	191	110	189	131
	1,776	371	1,808	381

Work of the Health Department.—Six million pounds' weight of adulterated and harmful foods was destroyed by the Health Department of New York during the last twelve months.

Vacancy in St. Chrysostom's Dispensary.—The position of physician in charge is vacant in this dispensary, situated at Thirty-ninth Street and Seventh Avenue. Applicants should apply in person or by letter to the Reverend Thomas H. Sill, vicar of St. Chrysostom's Chapel, Thirty-ninth Street and Seventh Avenue.

For a Postgraduate Course in Anatomy.—The trustees of the New York Postgraduate Medical School and Hospital have rented the house at No. 303 East Twenty-first Street, one block from the main building, and will fit it up for instruction in practical anatomy, a contribution for this purpose of \$1,500 a year for two years having been obtained by a member of the faculty.

New York State Medical Association.—The New York county branch of this association will hold its annual meeting on Monday, April 17, 1905, at 8 p. m. An election of officers will be held and the following programme discussed:

Presentation of Clinical Cases or Reports, Pathological Specimens, New Instruments, etc.; papers: Galvanism as a Curative Agent in Nervous Diseases; the Importance of Equipment and Technics, by Dr. W. B. Pritchard; discussion by Dr. George W. Jacoby, Dr. J. J. MacPhee, Dr. W. J. Morton, and Dr. Milton Franklin; Clinical Features and Treatment of Epidemic Cerebrospinal Meningitis, by Dr. Francis Huber; discussion by Dr. Marris Manges, Dr. Harlow Brooks, Dr. Christopher Colles, Dr. Thomas W. Darlington, and Dr. Herman M. Biggs. William Ridgely Stone, M. D., secretary.

American Gastroenterological Association.—The eighth annual meeting of this association will be held at the Academy of Medicine, New York, Monday and Tuesday, April 24 and 25, 1905, when the following papers will be presented:

The president's address, by Dr. S. J. Meltzer, of New York; Recent Advances in the Knowledge of the Movements and Innervation of the Alimentary Canal, by Dr. Walter B. Cannon, of Boston, Mass.; Recent Advances in the Knowledge of the Chemical Processes of Digestion, by Dr. Lafayette B. Mendel, of New Haven, Conn.; Are the Milk Coagulating and the Proteolytic Effects of the Gastric Juice Due to One and the Same or to Two Different Enzymes? by Dr. John C. Hemmeyer, of Baltimore, Md.; The F. A. Hoffmann-Ostwald Method of Determining the Free Hydrochloric Acid of Gastric Juice by Dissociation of Methyl Acetate, by Dr. John C. Hemmeyer, of Baltimore, Md.; On the Determination of the Free Hydrochloric Acid in Gastric Contents by the Physical Method of Hoffmann, with Report of an Unusual Case, by Dr. John P. Sawyer, of Cleveland, Ohio; The Immediate Effect of Biliary Retention on the

Gastric Secretion, by Dr. Julius Friedenwald, of Baltimore, Md.; Neuere Untersuchungen über die Titration der Magensäfte und über die Fermente des Magens, Speziell über das fettspalende Ferment, by Dr. F. Volhard, of Giessen, Germany; Diverticulum of the Esophagus, with Report of Cases, by Dr. William Gerry Morgan, of Washington, D. C.; Further Remarks on Ischochymia and Its Treatment, by Dr. Max Einhorn, of New York; Sarcoma of the Stomach, with the Report of Two Cases, by Dr. Morris Manges, of New York; Two Cases of Epilepsy, Resulting from Gastro-intestinal Disturbance, by Dr. Frank H. Murdoch, of Pittsburgh, Pa.; On the Relations of Some of the Metabolic Diseases to Intestinal Disorders, by Dr. T. B. Fletcher, of Baltimore, Md.; Diagnosis of Gastric Area with Special Reference to Transposition of Viscera, Sling-Stomach and Hour Glass Stomach, with Case Reports, by Dr. A. L. Benedict, of Buffalo, N. Y.; Comparison of the Methods of Lavage with the Siphon Tube and Kuttner Bulbs, by Dr. John P. Sawyer, of Cleveland, Ohio; Occult Blood in Fæces, by Dr. J. Dutton Steele, of Philadelphia, Pa.; A Case of Gastrocolic Fistula, by Dr. J. Kaufmann, of New York; Ætiology and Serum Treatment of Dysentery: (a) by Dr. Simon Flexner, of New York; (b) by Dr. William H. Park, of New York; discussion by Dr. John Henry Huddleston, of New York, and Dr. I. Adler, of New York; Clinical Features and Medical Treatment of the Benign Stenoses of the Pylorus, by Dr. Henry L. Elsner, of Syracuse, N. Y.; Surgical Treatment of the Benign Stenoses of the Pylorus, by Dr. George Emerson Brewer, of New York; discussion by Dr. S. W. Lambert, Dr. Howard Lilienthal, Dr. Edward Quintard, Dr. Joseph A. Blake, and Dr. J. Kaufmann, of New York; On Onomatologia Gastrologica, by Dr. A. Rose, of New York.

PHILADELPHIA.

Personal.—Dr. David L. Edsall has been appointed assistant professor of medicine in the medical department of the University of Pennsylvania.

Wills Hospital observed April 3rd as donation day. The hospital was founded in 1832 for the treatment of the various diseases of the eye. During the past year 13,000 patients were treated in its various clinics.

Bazaar by Methodist Hospital Nurses.—The graduate nurses of the Methodist Episcopal Hospital will hold a bazaar on April 18th and 19th in order to complete the fund of \$10,000 necessary to endow a private room in the hospital. Many novel features have been promised.

The University of Pennsylvania Representatives on the American National Committee of the Fifteenth International Medical Congress who have been appointed by the trustees are Dr. John H. Musser, Dr. Charles H. Frazier, Dr. B. Alexander Randall, Dr. William G. Spiller, and Dr. Horatio C. Wood.

Philadelphia Polyclinic.—During March the following work was done at the Polyclinic Hospital: Patients admitted to house, 109; patients discharged, 89; new patients treated in dispensary, 1,866; total visits to dispensary, 8,964; accident ward, 672. The week ending April 8th was a special week devoted to diseases of the eye. The various lectures and demonstrations were well attended.

College of Physicians.—At the meeting of the College of Physicians held Wednesday, April 5th, Dr. S. Weir Mitchell, Dr. W. W. Keen, and Dr. John S. Billings gave medical reminiscences of the civil war. A portrait of Dr. Horatio C. Wood was presented to the college. The honorary li-

brarian announced the addition of seventy-four volumes to the library during March. Mrs. Harrison Allen, through Dr. Keen, presented the Mutter Museum with a number of surgical instruments which belonged to the late Dr. Harrison Allen. At the conclusion of the meeting an informal reception was held and a light supper was served at the University Club.

Scientific Society Meetings for the Week Ending April 22, 1905.—Monday, April 17th, Medical Jurisprudence Society; Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, April 18th, Section on Ophthalmology, College of Physicians; Dermatological Society; Academy of Natural Sciences. Wednesday, April 19th, Philadelphia County Medical Society (business meeting for members only); Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants of Wills Hospital. Friday, April 21st, University of Pennsylvania Medical Society; American Philosophical Society.

Charitable Bequests.—In adjudicating the estate of James Carlisle, who died on July 17, 1902, Judge Ashman awarded the following amounts: Presbyterian Home for Aged Couples, \$500; Home for Incurables, \$500.

By the will of James Dundas Lippincott, who died recently, the property 1340 Lombard Street is bequeathed to the Visiting Nurses' Society of Philadelphia, to be known as the Alice Lippincott Memorial. The Home for Indigent Widows and Single Women of Philadelphia receives \$5,000.

The Children's Hospital of Philadelphia receives \$5,000 as a memorial to Agnes Dundas Lippincott, mother of the testator. The Episcopal Hospital and Colony Farm receives \$5,000. The Academy of Natural Sciences of Philadelphia receives \$5,000.

Medical Society Programmes.—The following was the programme of the Pathological Society of Philadelphia at its meeting held March 9th:

Dr. A. J. Smith and Dr. B. S. Veeder exhibited specimens of Solenophorus Megacephalus; Dr. H. R. Alburger, Secondary Sarcoma of the Liver, Hypertrophy and Atrophy of the Kidney, Amyloid Disease Due to Pott's Disease; Dr. H. Fox, The Nature of Paratyphoid Fever and Its Closely Allied Infections; Dr. D. Riesman will present a specimen of Ulcerative Endocarditis.

The following was the programme of the Philadelphia Pædiatric Society at its meeting held March 14th:

Dr. Eleanor C. Jones showed a Family of Five Children with Multiple Exostoses; Dr. D. J. Milton Miller, a Case of Chondrodystrophy Fetalis; Dr. Charles W. Burr, a Case of Stuporous Insanity at Puberty; papers: Dr. J. P. Crozer Griffith reported a Fatal Case of Chorea; Dr. R. Max Goeppe, a Case of Necrotic Stomatitis Following Pneumonia and Measles.

The following was the programme of the section in otology and laryngology, College of Physicians, at its meeting, March 15th:

Dr. George M. Marshall, a Case of Clonic Spasm of Laryngeal and Pharyngeal Muscles, following Cranial Injury; Dr. B. Franklin Royer, The Complications and Sequelæ Met with in Laryngeal Diphtheria.

The Health of the City.—During the week ending April 1, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Malarial fever.....	1	0
Typhoid fever.....	231	32
Scarlet fever.....	42	2
Chickenpox.....	50	0
Smallpox.....	1	0
Diphtheria.....	52	3
Cerebrospinal meningitis.....	5	4
Measles.....	50	1
Whooping cough.....	13	1
Tuberculosis of the lungs.....	62	58
Pneumonia.....	74	70
Erysipelas.....	12	3

The total mortality was 545, in an estimated population of 1,438,318, corresponding to an annual death rate of 19.70 per 1,000 population. The total infant mortality was 130; 102 under one year and 28 between one and two years. There were 41 still births; 24 males and 17 females. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 10; puerperal fever, 1; dysentery, 1; diarrhoea and enteritis under two years, 23. The temperatures reported by the United States Weather Bureau have been high; on March 29th the maximum temperature was 79°. The number of cases of typhoid fever reported, 231, was 75 less than the number reported during the previous week. The distribution of the cases is the same as heretofore described in these columns.

Proposed Legislation Concerning Milk Dealers.—A delegation of thirty members of the Philadelphia Milk Exchange went to Harrisburg on March 7th and appeared before the committees of public health and sanitation of the house and senate with the following requests: (1) That the food adulteration bill be amended to exempt milk and cream; (2) that a bill prepared by the exchange making special provisions against the adulteration of milk be enacted into a law; and (3) that the bill giving the Bureau of Health of Philadelphia arbitrary power over the milk dealers and compelling them to take out licenses subject to the rules of that bureau be defeated. The president of the Philadelphia Milk Exchange pointed out that his organization represents the handlers of the milk product of 8,000 farms, and that they are already under the jurisdiction of the Bureau of Health of Philadelphia, the Dairy and Food Commissioner, and the State Live Stock Sanitary Commission and subject to twenty-six State laws and six city ordinances. He feels as though his organization is already surrounded by enough restrictions. The bill which is now before the Legislature which will make the milk dealers take out licenses is objected to because it will impose an additional tax on the milk dealer who already pays a personal property tax, a property tax (if he has any property), and a mercantile tax. Its worst feature, however, is the arbitrary power it gives to the health authorities. It was pointed out during the session of the committees that only 8 per cent. of the samples of milk taken throughout the State were not absolutely pure, and that in the city of Philadelphia only 1 per cent. was not up to the standard. The

new bill which the milk exchange proposes to offer prohibits all forms of adulterants and all chemical preservatives; but provides that no person shall be liable to penalties if it can be shown that he could not, with reasonable diligence, have ascertained that the milk or cream was adulterated, impure, unwholesome, or preserved. It further provides that when a sample of milk or cream is taken for analysis one half shall be returned to the dealer with notice that the other half is to be analyzed.

GENERAL.

Change of Address.—Dr. W. W. Nelson, to Fairmount, Va.

The Kansas City Hospital Training School for Nurses has recently graduated the following young women: Mrs. Elizabeth Wayne Canfield, Miss Mary Pearl Hetrick, Miss Elva Maybeth Patton, Miss Nellie Holmes, Miss Lulu Hunt, Miss Emma Delia Fandell, Miss Josephine Reidy.

The Medical Association of the District of Columbia held its semiannual meeting April 4th at 8 p. m. Officers were elected for the ensuing year as follows: President, Dr. Clifton Mayfield; vice-presidents, Dr. D. Olin Leech, Dr. G. Brown Miller; secretary, Dr. D. W. Prentiss; treasurer, Dr. Frank Leech.

Johns Hopkins University.—Dr. William S. Thayer, who was elected to the chair of clinical medicine in the Johns Hopkins Medical School on April 3rd, has returned to Baltimore from Richmond. He will assume his new duties at the opening of the next scholastic year. With Dr. Llewellys Franklin Barker he divides the duties of the position held by Dr. William Osler.

Beaufort County, S. C., Medical Association.—This association was organized on March 29th with the following officers: President, Dr. H. M. Stuart, Sr.; vice-president, Dr. J. B. Thompson; chairman of county board, Dr. C. M. Guffin; secretary and treasurer and delegate to the State Association, Dr. M. G. Elliott; censors, Dr. M. B. Cope and Dr. W. R. Ewe.

The Banquet to Dr. Osler.—Dr. Joseph Ransohoff, Dr. C. A. L. Reed, and Dr. Fred Forchheimer, of Cincinnati, have taken great interest in the arrangements for the banquet to be given Dr. William Osler, of Johns Hopkins University of Baltimore, on his departure from America. Within the last few days correspondence has been had with many of the leading physicians in the country, who have responded enthusiastically to do honor to their colleague. The banquet will be held in the Waldorf-Astoria Hotel, in New York city, on May 2nd, as stated in a recent issue of this Journal.

Medical College of South Carolina.—The following graduates received their diplomas on April 5th:

Edwin Marshall Allen, of Florence; Charles Pinckney Bull, Jr., of Charleston; Zophar M. Bardin, of Charleston; Robert Black, of Bamberg; Edward M. Boykin, of Camden; E. M. Carson, of Sumter; James E. Daniel, of Charleston; J. D. Eady, of Johnsonville; O. D. Hammond, of Blackville;

Eugene L. Jagar, of Charleston; J. Martin Klink, of Charleston; Allen J. Jervey, of Charleston; Oscar LaBorde, of Columbia; R. E. Mathias, of Irme; McMillian K. Mazyck, of Charleston; J. C. Moore, of Lake City; Samuel A. Morrall, of Edgefield; W. Cyril O'Driscoll, of Charleston; E. W. Simons, of Summerville; A. C. Smith, of Glenn Springs; J. Lewis Smith, of Williston; Charles A. Speissegger, of Charleston; Elias Doar Tupper, of Summerville; John F. Wilson, of Dovesville; J. LaBruce Ward, of Georgetown; William Anderson Woodruff, of Pacolet; and H. H. Workman, of Woodruff.

Medical Graduates of Queen's Medical College, Kingston, Canada.—The following received their diplomas from this institution on April 4th:

H. J. Bennett, of Gananoque; Joseph Chant, of Chantry; J. H. Code, of Kingston; E. C. Consitt, of Perth; J. A. Corrigan, of Kingston; W. H. Dudley, of Pembroke; J. G. Dwyer, of Kingston; J. Y. Ferguson, of Renfrew; E. A. Gaudet, of Moncton, N. B.; A. W. Girvin, of Stella; M. E. Grimshaw, of Wolfe Island; R. W. Halladay, of Elgin; J. T. Hogan, of Perth; J. M. Hourigan, of Smith's Falls; A. H. Hunt, of Bridgetown, Barbadoes; M. Leses, of Kingston; M. Locke, of Brinston's Corners; T. D. MacGillivray, of Kingston; D. L. MacKinnon, of Lake Ainslie, N. S.; A. D. MacMillan, of Finch, Ont.; A. E. Mahood, of Kingston; P. A. McIntosh, of Dundela; C. R. Moxley, of Kingston; G. R. Randall, of Seely's Bay; M. E. Reynolds, of Athens; R. G. Reid, of Kingston; J. J. Robb, of Battersea; W. M. Robb, of Lunenburg; B. A. Smith, of Hartington; W. A. Smith, of Kingston; J. F. Sparks, of Kingston; A. C. Spooner, of Latimer; E. W. Sproule, of Harrowsmith; R. W. Tennant, of Belleville; John Turnbull, of Lowville; C. M. Wagar, of Enterprise; F. R. W. Warren, of Balderston; J. W. Warren, of Harper; H. J. Williamson, of Kingston.

American Medicopsychological Association.—

The sixty-first annual meeting of this association will be held at San Antonio, Texas, April 18, 19, 20, and 21, 1905. The following papers will be read:

The Unity of the Manifestations of Insanity, by Dr. H. A. Tomlinson, of St. Peter, Minn.; Perils of Psychiatry, by Dr. W. A. Gordon, of Winnebago, Wis.; Neuropsychic Asthenia and Its Psychiatric Aspects, by Dr. Charles H. Hughes, of St. Louis, Mo.; The Prevention of Insanity in Its Incubation by the General Practitioner, by Dr. J. T. W. Rowe, of Ward's Island, N. Y.; Final Report Upon the Relation of Insanity to Cardiac Diseases, by Dr. Arthur McGugan, of Denver, Colo.; Expert Testimony on the Doctor in Court, by Dr. D. R. Wallace, of Waco, Texas; Korsakoff's Psychosis, by Dr. A. W. Hurd, of Buffalo, N. Y.; The Therapeutic and Medicolegal Features of Drug Addictions, by Dr. George P. Sprague, of Lexington, Ky.; Melancholia, the Psychical Expression of Organic Fear, by Dr. J. W. Wherry, of Clarinda, Ia.; Psychoses of Anæmia, by Dr. Frank P. Norbury, of Jacksonville, Ill.; Mysophobia, with Report of Case, by Dr. John Punton, of Kansas City, Mo.; Cholemia; Its Relations to Insanity, by Dr. R. J. Preston, of Marion, Va.; A Case of Huntington's Chorea, by Dr. Harry W. Miller, of Taunton, Mass.; Nature of Practice in Neurology, by Dr. Arthur McGugan, of Denver, Col.; The Liver and Its Relations to Mental and Nervous Diseases, by Dr. Charles G. Hill, of Baltimore, Md.; As to Surgery for the Relief of the Insane Condition, by Dr. M. E. Witte, of Clarinda, Ia.; Observations on Some Recent Surgical Cases in the Manhattan State Hospital, East, by Dr. John R. Knapp, of Ward's Island, N. Y.; A Preliminary Report of the Gynecological Surgery in the Manhattan State Hospital, West, by Dr. LeRoy Broun, of New York city; Some Observations on the Relations of the Gastrointestinal Tract to Nervous and Mental Diseases, by Dr. Robert C. Kemp, of New York city; Tuberculosis Among the Insane, by Dr. C. Floyd Haviland, of Ward's Island, N. Y.; Masked Epilepsy, by Dr. Gershon H. Hill, of Des Moines, Ia.; Epilepsy as a Symptom, by Dr. Everett Flood, of Palmer, Mass.; Clinical Notes on Dementia Paralytica, by Dr. E. C. Dent, of Ward's Island, N. Y.

A Judicial Decision Interesting to Surgeons.—Hospital surgeons attending "emergency" cases

cannot subsequently recover payment from the patients is the substance of Judge Sutherland's decision of the case of Dr. N. M. Collins against John Meyer. Albert Meyer was injured in a factory accident and taken to the Homeopathic Hospital, of Rochester, N. Y. His father, the defendant, said he agreed with the hospital for care of the boy, not with Dr. Collins personally. The Municipal Court found against the physician, and the County Court has sustained that view of the general proposition involved. The learned judge said *inter alia*:

There is a statute which is quite suggestive, being chapter 893, L. 1896. It reads as follows:

"In any city . . . of this State wherein exists or is hereafter created an ambulance service, supported wholly or partly at public expense, or which is wholly or partly under the care, management, or control of public authority, no person in charge of the ambulance, hospital, or house or place of reception for the sick or injured shall refuse, in answer to a call or demand for the ambulance and which call has been answered by the attendants of the ambulance, to take such person or persons for whom the call may be made, to the hospital or place of reception for the sick or injured from which the ambulance came, for examination or treatment by the house authorities of the said hospital or place of reception for the sick or injured. Any person or persons neglecting or refusing to comply with the provisions of this act shall be guilty of a misdemeanor. This act shall apply to the drivers of or physician or physicians in charge of such ambulance."

Considering this act and the purpose for which the ambulance service is instituted in the city of Rochester, it seems that when an emergency case is brought to a hospital in an ambulance through a public call, the hospital is expected to furnish for such patient its house or staff physicians' immediate care, of a surgical or medical nature, which is at once necessary, until arrangements can be made for the further care of the case; and unless there is a promise to pay or some special arrangement, the first treatment in such emergency cases by the house physician or member of the staff whose duty as such it is to attend thereon, does not entitle him to claim compensation as he would in an ordinary case.

In this case the conversation between the superintendent of the hospital and the defendant, to the effect that the expense would be \$7.00 a week, is consistent with the contention that inasmuch as this was an emergency case, taken to this hospital because the accident occurred within that hospital district, it was not expected that the services of the physician in reducing the fracture were to be paid for by the boy's father.

Growth of Manitoba Medical College.—The needs of the Canadian Northwest and the growth of the population there are shown in the fact that the first Manitoba Medical College erected is no longer able to accommodate the yearly increasing student classes who assemble within its portals, nor is its equipment adequate properly to teach modern discoveries in surgery, and therefore the Manitoba college has found it imperative to build a new and larger college, in order not only to provide more room, but in order that the students may have the fullest advantage of the latest and best means for acquiring knowledge. The plans have now been completed, and the contract for the erection of the building will be let forthwith. The site of this college is on Emily Street, convenient to the General Hospital. Its structure will be three stories high above the basement

walls, and built of solid brick and stone. In the basement there will be a lounging room for the students, preserving room, toilet room, etc., the remaining space being used for ventilation apparatus, boiler and fuel rooms, and janitor's apartments. On the ground floor there is an office for the secretary, a room for the faculty, library, museum, spare room, storeroom, and toilet room. The first floor is divided into two lecture rooms, one having a seating capacity for 90 and the other for 130 students. On the second floor there is a dissecting room and prosecuting room. The floors throughout are of concrete on expanded metal, while the walls, staircase, and elevator walls are of red pressed brick. The stair frame is of iron with slate treads. The building will be heated with steam. The size of the structure is 60 by 100 feet.

Health in Michigan During March, 1905.—Reports to the State Board of Health, by representative physicians in active general practice, in different parts of the State, show the diseases which caused the most sickness in Michigan, during the month of March (five weeks ending April 1st), 1905, to have been as follows:

Diseases arranged in order of greatest prevalence in this month:	Mar., 1905.	Number of reports received for this month		Per cent of reports stating presence of disease.	Average for March, all 10 years, 1895-04.	Averages for March, 1895-04.
		296	296			
Rheumatism	68	67	69	62	62	62

At the State Capitol for the month of March 1905, compared with the average for March in the ten years, 1895-1904, bi-daily observations show the prevailing direction of the wind to have been northeast and southeast, instead of northwest, the velocity 1.5 miles per hour less, the average temperature 4.62 degrees higher, the average daily range of temperature 2.48 degrees greater, the precipitation .16 of an inch less, the average daily range of atmospheric pressure .063 of an inch less, the absolute and relative humidity more, the day and night ozone less, and the depth of water in the observation well 12 inches less (the well was dry). For the month of March, 1905, compared with the average for March in the ten years, 1895-1904, smallpox was more than usually prevalent; and pleuritis, pneumonia, erysipelas, intermittent fever, inflammation of bowels, measles, remittent fever, diphtheria, inflammation of brain, and meningitis was less than usually prevalent.

THE MOST DANGEROUS COMMUNICABLE DISEASES.

Including reports by regular observers and others, meningitis was reported present in Michigan during the month of March, 1905, at 13 places; whooping cough, at 18 places;

diphtheria, at 59 places; measles, at 79 places; typhoid fever, at 95 places; smallpox, at 101 places; scarlet fever, at 133 places; pneumonia, at 144 places; and consumption, at 221 places. Reports from all sources show meningitis reported present at 6 places more; whooping cough, at 2 places more; diphtheria, at 5 places less; measles, at 11 places more; typhoid fever, at 2 places more; smallpox, at 5 places less; scarlet fever, at 28 places more; pneumonia, at 2 places more; and consumption, at 30 places less, in the month of March, 1905, than in the preceding month. Frank W. Shumway, secretary.

Statement of Mortality in Chicago for the Week Ending April 8, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	April 8, 1905.	April 1, 1905.	April 9, 1904.
Total deaths, all causes	512	577	562
Annual death rate per 1,000	15.40	15.11	15.21
By sexes—			
Males	304	323	319
Females	208	254	243
By ages—			
Under 1 year	104	134	97
Between 1 and 5 years	57	54	31
Over 60 years	90	122	130
Important causes of death—			
Acute intestinal diseases	22	30	30
Apoplexy	15	17	16
Bright's disease	44	56	42
Bronchitis	14	21	21

Suicide	9	11	6
Typhoid fever	4	6	5
Violence (other than suicide)	27	25	27
Whooping cough	14	10	6
All other causes	113	98	120

Measles and whooping cough are the two diseases giving the health department most concern at present. Notwithstanding the frequent warnings of the *Bulletin* they have been allowed to spread through sheer carelessness of parents and others until they are now well nigh epidemic. As recently pointed out these two scourges of childhood are as important to the student of preventive medicine as scarlet fever, or diphtheria, or even smallpox. Their prevention presents peculiar difficulties. For instance, the indifference of the public, shared by the profession, the failure of many patients to see a physician, their contagiousness at a time when they cannot be recognized, and the variable length of time that they remain virulent. They are officially classed as dangerous to the public health, but are dealt with more leniently than some of the communicable diseases, because of the prevalent apathy toward their spread. There is not sufficient unanimity among doctors as to the necessity of preventing these diseases. The schools offer the best opportunity for their spread. There should be a change of sentiment among parents and teachers in regard to colds. In catarrhal diseases of all kinds affecting the upper air tracts the child should be excluded from the school. The early communicability of measles and whooping cough must never be overlooked. Health officials and physicians must work together to isolate these diseases until the symptoms of the sequelæ and complications as well as of the primary disease are well passed.

PRESSE MEDICALE.

March 4, 1905.

1. Scopolamine as a General Anæsthetic in Surgery,
By F. TERRIER and A. DESJARDINS.
2. Mechanism of Epiphyseal Detachment, By A. BROCA.

1. **Scopolamine as a General Anæsthetic.**—Terrier and Desjardins give as the advantages of this method of inducing general anæsthesia absence of operative apprehension and of the excitation which precedes muscular relaxation, absolute loss of consciousness and of memory, a prolonged sleep (eight or ten hours), absence of vomiting, nausea, or malaise, quietude of the patient, who sleeps the following night without the aid of morphine, non-production of albuminuria, that it can be used in cases of tuberculosis, heart disease, and cachexia, and that the anæsthesia persists for a long time after the patients have awakened from the sleep. The disadvantages given are the uncertainty of its action, one patient going to sleep quietly and completely, another with difficulty and incompletely so that a certain quantity of chloroform needs to be given in addition. Second, a vasodilatation which renders very careful hæmostasis necessary. Third, a contraction of the abdominal walls which contraindicates the use of this method in abdominal operations. As the use of scopolamine for general anæsthesia has been denounced by some as dangerous to life, these authors analyze twelve fatal cases in which this drug was employed, reported by different surgeons, and try to show that death was due in each to other causes and not to the anæsthetic.

2. **Epiphyseal Detachment.**—Broca presents an interesting study of the mechanics of this traumatic lesion so often met with during the period of growth of the long bones. The article is illustrated by forty-five plates, to which reference is so constantly made that an abstract is difficult. In general, it may be said that two mechanisms are possible; the epiphysis may be detached by a directly applied violence, or by ligamentous traction.

March 8, 1905.

1. The Rôle of the Œsophagosally Reflex in Deglutition,
By Professor H. ROGER.
2. Iliac and Pelvic Glandular Phlegmon Following Lymphangitis of the Lower Extremity,
By M. SAVARIAUD.
3. History of a Palpebral Epithelioma,
By A. TROUSSEAU.

1. **Œsophagosally Reflex.**—From experiments on a dog Roger learned that excitation of the œsophagus stimulates the functional activity of the salivary and buccal glands. The abundant secretion thus produced stimulates the pharynx which calls into play œsophageal contractions.

2. **Iliac and Pelvic Glandular Phlegmon.**—Savariaud reports three cases of this nature, and draws the following conclusions:

1. An abscess of the iliac fossa or of the pelvis

frequently follows lymphangitis of the lower extremity.

II. Suppuration of the external or internal iliac glands is always preceded by inflammation and suppuration of the inguinal glands, which form the first focus of lymphangitic infection.

III. The seat of the retroperitoneal collection is sometimes in the iliac fossa above the crural arch, sometimes in the prevesical space behind the rectus. The development of the abscess is accompanied by frequency of micturition from irritation and compression of the bladder.

3. **Palpebral Epithelioma.**—Trousseau presents the history of a case of epithelioma of the lid. It was removed, recurred, was treated with the x ray without benefit, and finally an extensive operation was performed to remove all the diseased tissue. The author feels confident in the belief that this last operation will prove curative.

March 11, 1905.

Confined Air and Tuberculosis,

By RAOUL BRUNON.

Confined Air and Tuberculosis.—Brunon protests against the fear of air, aerophobia, which he says has possessed all the French people. He cites cases to show the effect of living in a closed room and then in the open air, and pleads for a more common habit of keeping the windows of the sleeping room open at night.

March 15, 1905.

The Struggle Against Ankylostomiasis in Germany,

By EDOUARD FUSTER.

Ankylostomiasis.—Fuster presents a table which shows that between the years 1896 and 1902 the proportion of this disease had increased among the miners of Rhenish Westphalia from 6.4 per mille to 52.9 per mille. This rapid increase attracted attention and caused the institution of measures intended to combat the disease. These measures may be divided into two classes, those devoted to rendering the mine hygienic and those directed to the health and habits of the personnel. The hygienic measures in the mines consisted in the establishment of dressing rooms, lavatories, and impermeable, covered, and movable closets, the exclusive use of which was rigidly enforced, and in the use of disinfectants. The measures directed to the personnel consisted in the examination of all workmen for the parasites and the refusal to allow them to work unless they had certificates stating that they were free from the disease. In one mine twenty per cent. of the workmen were found to be infected. The enforcement of these rules was carried out against great opposition and with much difficulty. The daily press raised a continuous howl of protest both against the medical treatment and the loss of wages which was occasioned. The workmen objected to paying the cost of the certificate of examination, an expense which was borne by some of the mines, but not by the majority. Most serious perhaps was the fact that among the workmen the treatment itself of this disease is considered a calamity. Legends are current which have convinced them of the evils which await the unfortunate one who enters the hospital to take "the great, black pills"

of extract of filix mas. But in spite of all these difficulties which have been encountered the system has been persisted in, and in the autumn of 1904 had resulted in a great diminution of the disease.

SEMAINE MEDICALE.

March 8, 1905.

1. Cure of Myxœdema by Thyroid Grafting,
By Professor H. CRISTIANI.
2. Provisory and Preventive Hæmostasis in Scapulohumeral and Coxofemoral Disarticulations and in Amputations of the Upper Limbs, By E. ESTOR.

1. **Cure of Myxœdema by Thyroid Grafting.**—Cristiani reports the case of a woman, 23 years old, on whom thyroidectomy had been performed and who was suffering from severe symptoms of myxœdema. Treatment by ingestion of the liquid extract of the thyroid gland was first instituted and a considerable amelioration of the symptoms obtained, but it was impossible by this means to cause the entire myxœdematous tumefaction to disappear. Finally tissue taken from a healthy thyroid was introduced subcutaneously through four incisions, three grafts being placed in one incision, four in all the others. The result was excellent.

2. **Hæmostasis in Disarticulations and Amputations.**—Estor describes in a well illustrated article the apparatus he employs to prevent hæmorrhage when performing the operations named in the title.

ZENTRALBLATT FUER CHIRURGIE.

February 18, 1905.

1. The Technics of Plaster of Paris Jackets,
By MAX HAUDEK.
 2. Intestinal Obstruction as a Late Result of Appendicitis,
By V. SUBBOTITSCH.
2. **Intestinal Obstruction.**—Subbotitsch reports the case of a young man of twenty years of age who suffered from intestinal obstruction ten years after an attack of appendicitis. It was caused by a strangulation of a coil of small intestine by a band arising in the region of the appendix and extending to the root of the mesentery of the small intestine.

February 18, 1905.

1. Voluntary Production of Brachy- and Dolichocephaly of the Fœtal Head,
By G. WALCHER.
 2. The Bacillus Aerogenes Capsulatus in Puerperal Fever,
By H. M. LITTLE.
1. **Brachycephaly and Dolichocephaly.**—Walcher has made the interesting observation that one can influence the shape of the newly born child by maintaining certain positions. The infants which lie constantly on the occiput, become brachycephalic, those which lie on the side, dolichocephalic. Walcher says that this observation has a decided influence not only upon obstetric practice, but upon anthropological facts as well.
2. **Bacillus Aerogenes Capsulatus.**—Little has found this bacillus in ten cases of puerperal fever, nine times in pus from the uterus, once in a mammary abscess. In two cases it appeared alone, in eight associated with other bacteria (streptococci, staphylococci, gonococci). Little

observes a striking similarity between the gas bacillus and Pasteur's "septic vibrio." He also regards the gas bacillus as identical with the bacillus perfringens described by French authors.

ZENTRALBLATT FUER INNERE MEDIZIN

February 11, 1905.

1. Dyspnœa in Pneumothorax,
By L. HOFBAUER.
1. **Dyspnœa in Pneumothorax.**—Hofbauer says that in uncomplicated pneumothorax a pure expiratory dyspnœa is observed. In two fresh cases he has noted that while inspiration is entirely normal, the expiration is longer than normal, the chest is flattened and the auxiliary muscles of expiration are called into use. After the pneumothorax has lasted for some time inspiration becomes longer and more difficult, probably due to secondary changes in the lungs. At this stage the expiratory dyspnœa is not so apt to be called to the attention. Sauerbruch explains the dyspnœa of this condition by insufficient oxidation and consequent overloading of the blood with carbonic dioxide gas. The dyspnœa attendant upon mitral stenosis may be differentiated from that of pneumothorax by the fact that the expiration in the former is longer, but not so frequent, in the latter it is shorter and quicker.

February 18, 1905.

1. Lævulosuria and Diabetes Mellitus,
By G. GRAUL.
1. **Lævulosuria and Diabetes Mellitus.**—Graul says that there is an alimentary lævulosuria corresponding to alimentary glycosuria. If 100 grammes of grape sugar are taken on an empty stomach, they are not entirely converted in the intestinal tract. The condition is seen most frequently in those suffering from hepatic disease. The author narrates a case of a man with diabetes mellitus who also presented a lævulosuria, and in whom the liver was palpably enlarged and hard. When this patient took wine freely, lævulose could be found in the urine. This the author ascribes to disturbed function of the liver.

BERLINER KLINISCHE WOCHENSCHRIFT.

February 20, 1905.

1. A Case of Paralysis from Fright, By E. VON LEYDEN.
 2. Clinical Use of Streptococcus Serum, By F. MEYER.
 3. Dialyzed Diphtheria Toxines, By P. H. ROEMER.
 4. A New Case of Intrauterine Skeletonization,
By A. HIRSCHBERG.
 5. A Case of Congenital Pulmonary Stenosis, with Remarks on the Diagnosis of an Open Botallo's Duct,
By G. ARNHEIM.
 6. The Disinfecting Power of "Grisein,"
By E. FRIEDBERGER and W. OETTINGER.
 7. Local Anæsthetics and Analgetics, By G. FINDER.
 8. Treatment of Trachoma with Radium, By H. COHN.
2. **Clinical Use of Streptococcus Serum.**—Meyer used a serum derived from human infections prophylactically to avert erysipelas and scarlatina, and curatively in cases of sepsis. Improvement was noted in cases of angina with severe local and general symptoms and septic cases of diphtheria improved after simultaneous injections of diphtheria antitoxine. Severe cases of erysipelas likewise improved. Scarlet fever

was favorably influenced by the serum in so far as the fever and the general symptoms were concerned. In cases of puerperal sepsis it was of greatest use in puerperal endometritis. The use of the serum is contraindicated in cases in which vital organs are affected, such as ulcerative endocarditis, mixed tuberculous infections, and acute articular rheumatism.

4. Intrauterine Skeletonization.—Hirschberg reports such a case in a multipara. A four months' fetus became skeletonized, the bones being removed piecemeal from the uterus. The author regards the process as one of maceration rather than one due to putrefaction.

6. Griserin.—Friedberger and Oettinger have made numerous experiments to determine the internal disinfecting power of griserin. The experiments were made with special reference to tuberculosis and the drug was given in large doses. As far as the disease was concerned, all the results were negative, so that the claims for it as a powerful and harmless internal disinfectant—at least, so far as tuberculosis is concerned—must be disregarded.

7. Local Anæsthetics.—Finder recommends for submucous nasal anæsthesia, two c.c. of a one half per cent. solution of cocaine, to which four drops of adrenalin are added. In cases in which the contractile power of cocaine is not desired, he has found yohimbin (a one per cent. solution) useful. The treatment of ozæna seems to be enhanced by interstitial paraffin injections. The author remarks that patients with ozæna seem to be subject to tuberculosis.

February 27, 1905.

1. Isoform and Its Action in the Organism,

By F. ROCHMANN.

2. The Nature of the Hay Fever Poison and Its Specific Antitoxine,

By C. PRAUSNITZ.

3. Neumann's Orcin Reaction for the Determination of Sugar in the Urine,

By G. MANN.

4. Bismuth Poisoning,

By W. MAHNE.

5. Permanent Results After Bloodless Reduction of Congenital Dislocation of the Hip,

By G. JOACHIMSTHAL.

6. Recent Work on the Bacteria of the Tubercle Bacillus Group,

By KUTSCHER.

1. Isoform.—Rochmann describes isoform as a colorless, crystalline substance, not poisonous, and can be taken in doses of from two to four grammes daily. It is said to have an antiseptic action in the intestines, but too great stress is not to be laid upon this. It is, however, an excellent antiseptic for surgical purposes.

2. Hay Fever.—Prausnitz says that Dunbar's work has proven beyond doubt that hay fever is due to the pollen of graminaceæ, which float in the air in enormous quantities during the hay fever season. The toxine is probably of proteid character. It is likely that the antitoxine of Dunbar acts by causing an actual diminution of the toxins. The practical results of the use of the serum are excellent.

3. The Orcin Reaction.—Mann has used Neumann's test in many different sugar solutions. In the urine of diabetics he obtained a more decided reaction for dextrose than by Trommer's or Nylander's tests. It gives a reaction for levulose as well. There is one disadvantage in that albuminous urines do not always give a reliable test for dextrose. Urates and phosphates, however, do not seem to disturb the test.

4. Bismuth Poisoning.—Mahne reports the case of a delicate woman who was treated with a ten per cent. bismuth salve for a burn. After a few weeks she began to show signs of bismuth poisoning and a nephritis. The case ended fatally. At the autopsy, the mucous membrane of the entire colon was found to be stained black. The cause of the poisoning in this case is ascribed by the author to the extensive areas on the body to which the salve was applied.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE

February 19, 1905.

1. The Electroactivity of the Human Body,

By G. GARIBALDI and F. MARIANI.

2. Atheroma from Adrenalin and Atheroma in General,

By NICOLÒ MARINI.

3. Some Notes on the Gastroenteric Infections in Nurslings,

By VIRGLIO MAGGIONI.

4. The Ætiology of Little's Disease,

By GIUSEPPE CAJOZZO.

7. A Case of Internal Metrorrhagia,

By GIOVANNI GENNARI.

8. Albargin,

By FRANCESCO GIRARDI.

1. Electric Resistance of the Human Body.—Garibaldi and Mariani found that the resistance of the human body to electric currents passing from one hand to the other was between twenty and twenty-five ohms. The hands were immersed in salt solution at a temperature which was constantly 25° C., and the same surface of skin was always immersed. A very sensitive galvanometer was used to measure the current, and the tension used was about 2.20 volts. The resistance did not differ much when the patient's foot was immersed, instead of the opposite hand. In febrile patients the resistance diminished somewhat, but this was not constant. The resistance differed to the extent of eight or ten thousand ohms in different individuals. It differed to the extent of about ten per cent., according to the temperature of the surface exposed, and varied from seventeen thousand ohms in children to twenty-seven thousand in adults. From day to day it differed to the extent of twelve or fifteen per cent. in the same person. These variations are such that the measurement of the resistance of the body to electricity cannot, in the author's opinion, be made use of in pathology.

2. Adrenalin and Atheroma.—Recent studies on adrenalin have shown that eight doses injected into rabbits give rise at times to dilatation of the left ventricle, and to atheromatous patches in the aorta. Twenty doses produce a hypertrophy of

the ventricle and diffuse atheroma of the whole thoracic aorta, and ultimately aortic aneurysm (Josué). Marini does not believe that this atheroma is caused by the local irritant action of adrenalin on the wall of the artery. This is impossible, as the drug passes through the whole of the circulation without elsewhere irritating. It may be that the mere increase of tension which adrenalin produces gives rise to atheroma. Martin offers the theory that atheroma results from a sclerosis of the vasa vasorum feeding the arterial walls. The author inclines to the belief that hypertension is the cause of the malnutrition, and of the consequent atheroma in the arteries, both in adrenalin atheroma and in "clinical atheroma." In the latter the hypertension is due to toxic substances in the blood.

RIFORMA MEDICA.

February 25, 1905.

1. A Case of Diplococcic Septicæmia, By E. TEDESCHI.
2. A Case of Congenital Anomaly of the Heart (*To be continued*), By F. SICURIANI.
3. A Case of Hemiplegia in Pneumonia (*Concluded*), By CARLO FEDELI.
4. Surgical Intervention for Cirrhosis with Ascites (*III. Conclusion*), By ORESTE CIGNOZZI.
5. The Biology of Certain Anaerobes, and an Easy Method of Growing Them in Cultures (*III. Conclusion*), By GIULIO TAROZZI.

1. **Pneumococæmia.**—Tedeschi, of Genoa, adds a case to the collection of reports of generalized pneumococcus infection which appeared since Bozzolo first spoke of "pneumonia without any pneumonia." The patient was a girl aged nineteen years, who was first seized with what appeared to be an attack of acute articular rheumatism, except that salicylates did not affect the symptoms. Afterward the patient developed effusions and other inflammatory signs in the various large serous sacs, including the pleura and the peritonæum. The intraserous effusions were serofibrinous in character, and were rapidly absorbed. A noteworthy feature was the mildness of the general symptoms, and the absence of local symptoms and the normal or almost normal temperature. Pneumococci were found in the blood, the serous cavities, and the pharynx. The organs which are known to be especially predisposed to pneumococcus infection—i. e., the lungs, escaped in this case. The author thinks that the pharynx was the original port of entry, and that the rheumatic symptoms were also due to the pneumococcus which was found in the blood.

4. **Surgical Treatment of Ascites.**—Cignozzi concludes that surgical intervention is justified, and is apt to give good results in cases of ascites due to portal stenosis induced through various mechanical causes, such as pressure of enlarged glands, of cicatrices, of periphlebitis, endophlebitis, etc. On the other hand, in cirrhosis due to alcoholism, etc., in which the lesions are of the atrophic type, the type of Laennec, etc., there is less chance of a good result by artificial anastomosis of veins, and the mortality of the operation is far greater. In such cases the operation should be performed early, if at all, i. e., when the liver is still functionally active.

Severe hæmatemesis and enterorrhagia demand surgical interference. More encouraging results may be attained in hypertrophic cirrhosis, because the ascites in this form is apt to be mechanical in origin. Good results are obtainable with surgical treatment in cardiac cirrhoses, as well as in the infectious forms (Budd's and Banti's types), but in the latter the laparotomy assists the omental fixation in producing the desired effects. In acquired and congenital hepatic syphilis, the deviation of the portal blood by means of surgery can give good results, if the age of the patient, his general condition and his freedom from other lesions permit. In malarial cirrhoses, due to splenic hypertrophy, surgical treatment gives good results, especially when combined with splenectomy.

There is no such thing as "curing" a cirrhosis by means of surgical operations for the ascites. The results of the operation include a disappearance of the ascites which sometimes does not return. In some cases it also produces an improvement in the hepatic function. The operation also checks hæmorrhages from the stomach and intestines and generally improves the condition of the heart, the kidneys, and the blood of the patient.

5. **Anaerobes in the Intestines.**—TaroZZi cultivated certain germs, found in the intestines of man and of some animals, which have not been hitherto grown on the ordinary media. These germs are characterized chiefly by the formation of a terminal spore, making them look like drumsticks. The expedient which the author used to make them grow on ordinary media consisted in adding to these media sterile pieces of animal tissue, preferably from the parenchyma of the internal organs. Similar germs may be cultivated from putrefying tissues in the human cadaver. Other pathogenic germs, such as the bacillus of tetanus, the bacillus of symptomatic anthrax, etc., which hitherto have been considered anaerobic in the strict sense can be cultivated in the same manner.

1. On a Case of Resection of the Liver for a Tumor, By R. CALIRNI.
2. On the Influence of Natural Hypotonic Solutions of Sodium Chloride on the Secretion of the Stomach, By P. CASCIANI.
3. On the Action of Strychnine as a Cardiac Stimulant, By CARLO GENNARI.
4. The Transmission of Murmurs, and Relative Diagnostic Criteria, By GIUSEPPE CATTANI.
5. A Case of Congenital Anomaly of the Heart (*Concluded*), By F. SICURIANI.

1. **Resection of the Liver.**—Calirni reports a case of resection of the liver in a woman aged 36 years for a large malignant tumor of the right side of the organ. The symptoms were acute in character, and in all respects resembled those of a septic cholecystitis. This diagnosis having been made, the abdomen was opened with the intention of opening and draining the gall bladder; but, instead, a tumor composed of solid masses of easily bleeding tissue was found. The tumor was of the size of the head of a fœtus, and was continuous with the liver, without any pedicle. The gall bladder lay on one side of it, and was per-

fectly normal in appearance. The gall bladder was removed after preliminary ligature of its neck, which was fixed to the abdominal wall by means of a suture. The tumor was then surrounded with a rubber tube drawn tightly around its base, and removed with a scalpel. A stump as thick as a man's arm was left in the hepatic tissue, and this was surrounded with iodoform gauze, which was left between the hepatic stump and the margins of the incision. After a careful toilet of the peritoneal cavity, the lower part of the abdomen was closed. The stump gradually shrunk away and the rubber tube was removed after fifteen days. The gauze was gradually withdrawn and the stump allowed to granulate. The biliary fistula remained open for some time, but finally healed, and the patient was discharged cured. Histologically, the tumor proved to be a carcinoma derived from aberrant suprarenal glandular tissue.

2. Influence of Sodium Chloride Solutions on Gastric Secretion.—Casciani experimented on dogs with gastric fistulæ, according to Pawlow's method, with a view of determining the influence of mineral waters containing varying percentages of sodium chloride upon the gastric secretion. He found that hypotonic sodium chloride waters increase the secretion of hydrochloric acid, and of the gastric juice. Hypotonic mineral waters containing calcium bicarbonate, on the other hand, have no appreciable effect on the gastric secretion, or the excretion of hydrochloric acid in the stomach. The first class of waters mentioned are, therefore, indicated in diseases with diminished gastric secretion, while the last named class are suitable for cases with an increased secretion of hydrochloric acid, merely as mild stimulants to the stomach. One of the author's students, Coleschi, experimented clinically in patients with the same results as were obtained on dogs. The results obtained by Coleschi showed that hypotonic sodium chloride waters were more efficient as regards the increase of gastric secretion than hypertonic waters of the same class. Therefore, waters containing sodium chloride and hypotonic to the blood serum of normal man are especially adapted to the treatment of gastric diseases associated with a lack of gastric secretion or of hydrochloric acid secretion.

3. Strychnine as a Heart Stimulant.—Gennari concludes from a study of this question that strychnine is not a direct heart stimulant, and is contraindicated in erethistic and non-compensated cases. In these conditions strychnine either does not act at all or else, developing its cumulative action, makes the erethistic condition worse and increases the subjective discomfort of the patient. The action of strychnine upon the nervous system is to produce a vasoconstriction with an increase in the blood pressure, and therefore the drug is indicated in the adynamic and depressive forms in which the tone of the blood vessels is impaired. In debilitated or neurasthenic individuals it produces a noteworthy improvement in the general condition and increases the appetite and the strength of the patient.

4. Transmission of Murmurs as a Diagnostic Criterion.—Cattani has made a study of transmissions of murmurs, and declares that this element in a murmur is the most important of its diagnostic features. He found that both pericardial and cardiac sounds could be heard in many cases at a great distance from the heart, as, for instance, over the forehead, the arms, the abdomen, the iliac bones, the ankles even. Pericardial murmurs are transmitted along the bones, while aortic murmurs are transmitted along the blood vessels. He found also that the great difference between endocardial and exocardial murmurs becomes evident when we auscultate behind, over the vertebral column, at the level of the heart. He regards, in fact, the retrocardium as of the same importance as the præcordium in the diagnosis of cardiac lesions. The transmission of murmurs is modified also by the character, amount and location of pericardial exudates, as well as the presence or absence of hypertrophy in the heart muscle. Hypertrophy of the heart facilitates the transmission of murmurs. Pericardial murmurs (friction sounds) are distinguished by their superficial character, their diffuse transmission, and their variability with the position of the patient. When the pericardial exudate lodges chiefly anteriorly, the transmission takes place through the sternum and cartilages. When, on the other hand, the exudate is situated posteriorly, the sound is transmitted through the spinal column. Non-pericardial murmurs are transmitted also to the retrocardial region. Mitral murmurs may be heard posteriorly at the angle of the left scapula or in an oblique line from the spine towards that angle. Aortic murmurs on the other hand are heard in the suprascapular fossa, between the spine and the oblique line of the scapula.

ROUSSKY VRATCH.

February 10, 1905

1. On the Surgical Treatment of Affections of the Biliary Passages (*Concluded*), By M. M. KOUZNETSOFF.
2. On the Secretory Function of the Parotid Gland in Man (*To be continued*), By E. A. ZHERBOVSKI.
3. On the Pathology of the Kidneys (Preliminary Communication), By A. N. GECHTMANN.
4. The Treatment of Morphine Habitués, Alcoholics, and Smokers by Means of Hypnotic Suggestion (*Concluded*), By M. I. BEREZINSKI.

1. Surgical Treatment of Biliary Affections.—Kouznetsoff pleads for a more prompt surgical treatment of affections of the biliary passages and for a wider recognition of the value of surgery in these conditions on the part of the general practitioner. In most cases of simple gallstone disease or cholecystitis the establishment of a gall bladder fistula and drainage of the gall bladder, after the removal of the stones, effect a cure of the catarrhal condition, and rid the patient of his painful condition. Cases of chronic stenosis of the common duct due to the presence of stones, complicated with chronic jaundice and cholangitis, demand cholecystectomy or else choledochotomy with drainage of the common or the hepatic duct. Cholecystectomy is the most radical operation and offers the surest guarantee against a

recurrence of gallstone disease. The writer recommends the incision of Kehr as the most practical mode of reaching these structures and believes that the removal of the gall bladder, accompanied by ligation of the gall bladder artery and a separate ligation of the cystic duct, is a perfectly rational procedure. He obtained good results with tamponage after removal of the gall bladder by Kehr's method, and recommends the more extensive use of bacteriological methods in detecting the causes of gallstone disease during operations.

3. Studies in Renal Pathology.—Hechtmann's preliminary paper deals with researches, undertaken with a view of determining the very important question as to how much renal tissue can be removed in an animal without causing death. A second part of the work is devoted to the investigation of nitrogenous metabolism in dogs, together with clinical observations in the same animals after various operations on the kidneys. Sixteen experiments were performed in all, of which five related to the amount of renal tissue which could be removed without killing animals. The whole kidney or various portions of the organ were removed in different dogs. In the second series of eleven experiments, various operations were performed; for example, the removal of one half the medullary layer in one kidney and of the whole cortical substance in the other kidney. The results obtained were briefly as follows: The removal of three quarters of the total renal tissue available is not fatal, but so soon as this limit is overstepped the animal dies. The removed renal tissue is partly regenerated, partly compensated by hypertrophy, and partly becomes degenerated. After removing the greater part of the medullary substance, the clinical picture becomes one of interstitial nephritis, three to five months after the operation, and sooner or later some of the dogs develop uræmic symptoms. The nitrogenous metabolism always suffers after these operations, and the nitrogen of urea diminishes after the procedure to the extent of from eight to ten per cent.

4. Hypnotism as a Cure for Morphine Users, Drunkards, Etc.—Berezniitsky strongly advocates the employment of hypnotism in the treatment of drunkenness, the morphine and tobacco habits. The author argues that there are no drugs which can be hoped to cure these habits, and that modern medicine has found the most efficient means of combating them by means of mental suggestion. In connection with alcoholism and the combat against it in various countries, he mentions the prohibition laws existing in some of our States, but adds that such laws would be impossible in European countries. The governments of the American States which prohibit the sale of liquor, rightly calculate that the loss in revenue which is entailed by such laws is compensated to the State by the increased healthfulness of the population. On the other hand, the government monopoly of the liquor traffic as it exists in some countries (e. g., Russia), not only does not diminish the evil, but prevents its proper control. He advocates the establishment of outdoor services

where alcoholics can be treated hypnotically and of sanatoria, etc., where the worst cases can be confined for a time also under hypnotic treatment. As regards the treatment of the tobacco habit he advises that tobacco be prohibited entirely as soon as treatment is begun. No bad effects result from such a sudden removal of this drug as are noted in the case of opium. Hypnotism easily cures the tobacco habit, but the cures are not often permanent, as smokers resume the habit more easily than other drug habitués. They do not regard this habit as seriously as do morphine eaters. The results of treatment with hypnotism in alcoholics have been variously stated at from twenty to eighty per cent. of cures. The author thinks that thirty per cent. is the correct estimate and that the high figures given by some observers are due to enthusiasm over a new method of treatment. But even thirty per cent. of cures is a satisfactory result in alcoholism, a condition which so stubbornly resists treatment by other means.

By W. E. MUSGRAVE.
8. Dissemination of Streptococci Through Invisible Sputum in Relation to Scarlet Fever and Sepsis,
By ALICE HAMILTON.
9. Immunity. Chapter XI.

1. Hepatic Insufficiency.—Edgar places himself in that small class of obstetricians who believe that all the pathology of pregnancy and of the puerperium, apart from that due to malformations and traumatism, has its origin in hepatic insufficiency. The autotoxic state due to this insufficiency calls into being such affections as hyperemesis, acute atrophy of the liver, eclampsia, polyneuritis, etc. It is also probably responsible for such affections as gastric disorders, headaches, pruritus, chloasma, etc., so commonly seen in pregnancy. From this the author concludes: (1) The preventive treatment of much of the morbidity and mortality of pregnancy and of the puerperium depends on the early recognition of the autotoxæmia of pregnancy, as it shows itself in the clinical picture of hepatic insufficiency. (2) No one who has had an extensive obstetric experience can fail to observe that a large number of pregnancies are really pathological in their nature. That a specific toxæmia of pregnancy exists will probably soon be admitted on all sides.

It is, of course, very easy to attribute to the auto-toxic state certain symptoms of the pregnant woman which proceed from other sources; and it is by no means impossible that pregnancy may predispose to more than one toxic condition. In any case, however, the presence of the hepatic toxæmia must be borne in mind—whether it be the principal state or accessory to other facts. (3) Our present knowledge of the pregnant state demands that women at this time should be constantly under the observation of a competent physician. Pregnancy cannot be treated through the mails or over the telephone. It is not enough that a monthly or bi-monthly examination of the urine be made for symptoms of hepatic or of renal insufficiency, as such urinary analysis often fails completely to indicate the presence of toxæmia. A pregnant woman should be seen frequently by her physician and watched for general symptoms of the overcharging of the blood with toxic material, such as nausea and vomiting, headache, physical and mental lassitude, high arterial tension, alterations in character and disposition. Thus, and thus only, shall the physician do his whole duty by his patient.

7. **Amœbiasis.**—Musgrave's paper is founded on a large personal experience with amœbic dysentery and on 150 autopsies. The paper is very complete and makes many suggestions regarding the treatment and prophylaxis of the disease. Perhaps of special interest are the great variety of pathological conditions due to amœbiasis, which are capable of simulating appendicitis. Surgical intervention in most of these cases is contraindicated, and it is therefore of great importance that the subject should be well understood. In the 150 necropsies there were two cases in which an operation for appendicitis would have prolonged life. One of the these was amœbic appendicitis without extensive ulceration of the cæcum, and the other a pericæcal amœbic abscess.

BOSTON MEDICAL AND SURGICAL JOURNAL.

April 6, 1905.

1. The History of the Boston Society of Psychiatry and Neurology for Twenty-five Years,
By WALTER CHANNING.
2. Surgical Treatment of Nephritis. A Résumé,
By PAUL THORNDIKE.
3. Diet in Nephritis,
By HENRY JACKSON.
4. Some Further Observations on Leucocytotoxines,
By HENRY A. CHRISTIAN AND THOMAS F. LEEN.

2. **Renal Decapsulation.**—Thorndike concludes his résumé of the surgical treatment of nephritis with the following, not very encouraging, deductions: (1) The bulk of available evidence goes to prove that a new capsule is formed within a few weeks after decapsulation, and the establishment of a collateral circulation sufficient in degree to materially affect the renal tissues is not probable; (2) whatever may be the explanation of certain clinical facts adduced to justify decapsulation, they do not seem to offer a very promising foundation on which to base a sanguine hope that renal surgery has much of a future along the lines developed by Edebohl and his followers.

3. **Diet in Nephritis.**—Jackson, for the purpose in hand, divides nephritis into three types: acute, subacute, and chronic. No hard and fast rules can be laid down with regard to diet, yet, in a general way, it may be said: (1) In acute nephritis cut down the proteids and allow a fair amount of carbohydrates. Two or three pints of milk and some bread or cereals will be sufficient. (2) In subacute nephritis most patients need to be properly nourished, as they lead more or less active lives. They must have a fairly abundant proteid diet. The author believes that it is better to give the proteids in the form of eggs and meat than to strain the digestive organs with large quantities of milk. (3) In chronic nephritis the author advises a plain mixed diet.

4. **Leucocytotoxines.**—Christian and Leen report their method of studying leucocytotoxines. If the serum tested was capable of arresting the amœboid movements of leucocytes in five minutes, it was held to be leucocytotoxic. The leucocytotoxic sera were obtained by injecting emulsions of various tissues into animals of a different species. These experiments show the ease with which leucocytotoxines can be produced by the injection of a variety of somatic cells, as those of the spleen, liver, kidney, and cardiac muscle. Leucocytotoxic sera so produced are also hæmolytic and the specificity of such sera is analogous to that of hæmolytic sera. Cultures in bouillon of various bacteria contained no substance which was cytotoxic for the leucocytes of the guinea pig when tested by this method.

MEDICAL NEWS.

April 8, 1905.

1. Further Notes on the Function of the Parathyroid Glands, By W. G. MACCALLUM AND C. F. DAVIDSON.
2. Two Cases of Pernicious Anæmia Due to the Dibothriocephalus Latus, By ALFRED MEYER.
3. A Case of Dibothriocephalus Latus Infection, Causing Pernicious Anæmia; with Complete Recovery, By W. GILMAN THOMPSON.
4. Symptoms and Diagnosis of Cerebrospinal Meningitis, By HENRY L. ELSNER.
5. Eye Symptoms of Cerebrospinal Meningitis, By A. EDWARD DAVIS.

1. **The Parathyroid Glands.**—MacCallum and Davidson record in detail a number of experiments they have conducted upon animals for the purpose of further elucidating the functions of the parathyroid glands. They conclude: "On the whole, although the cases reported by Lusena and others in the literature have shown a milder course after thyreoparathyroidectomy than after parathyroidectomy, we cannot support this as a general rule, for in half of our cases the symptoms were of the maximum severity. Nor can we support Lusena's statement that subsequent thyreoidectomy stops the tetany, for in four out of six of our cases it had absolutely no effect and the dogs proceeded to a more and more violent tetany and died. We therefore regard the tetany not as the result of a disturbance of the thyreoid from the loss of the influence of the parathyroids, but as the direct result of the loss of parathyroid function, especially since it may be directly cured

by injection of parathyroid emulsion in the absence of the thyroid."

2. **Pernicious Anæmia.**—Meyer's patients both recovered. One of the patients was a Finn, the other a Russian Pole. The parasite was recovered from the first case, but not from the second. In both cases the diagnosis was based on an examination of the stools.

3. **Pernicious Anæmia.**—Thompson's case of pernicious anæmia due to the dibothriocephalus latus recovered, although the head of the parasite was never found in the stools. The patient was a Finn. The literature of the disease is rather extensively reviewed.

AMERICAN MEDICINE.

April 8, 1905.

1. The Significance of the Urinary Examination in Women, By GUY L. HUNNER.
2. The Optic and Ocular Factors in the Ætiology of the Scoliosis of School Children, By GEORGE M. GOULD.
3. The Advantages of Tendon Transplantation, By H. AUGUSTUS WILSON.
4. Extrauterine Pregnancy at Full Term; Total Extirpation of Uterus and Placenta by a New Technique: Recovery, By HIRAM N. VINEBERG.
5. Pathological Changes Resulting from Prostatic Enlargement, By CHARLES E. BARNETT.
6. Enterostomy, By J. W. LONG.
7. Two Cases of Landry's Paralysis: One Terminating in Recovery, the Other in Death, By THEODORE DILLER and C. L. BILLARD.

1. **Urine Examinations.**—Hunner pleads for more frequent examinations of the urine in cases of abdominal and pelvic disease. His paper concerns itself more with the importance than with the significance of urinary examinations in women.

3. **Tendon Transplantation.**—Wilson reviews the development of tendon transplantation from the time of Nicoladoni. The method is applicable to those cases in which function is faulty because of ill directed voluntary movements, and it aims to restore the balance of power as far as possible. It is applicable in traumatic loss of function of muscles and tendons; spastic paraplegia, infantile paralysis, and congenital deformities. Some of the earlier failures were due to the fact that too much was expected of the method. The advantages to be obtained from tendon transplantation are often greatly enhanced by producing ankylosis in an appropriate joint. The accepted methods of inserting transplanted tendons are conveniently grouped under four headings: 1. Dividing a tendon of a healthy muscle and suturing its central portion to a paralyzed tendon. 2. Dividing the tendon of a paralyzed muscle and attaching its peripheral portion to a healthy tendon is called ascending transplantation by Vulpius, and by Hoffa the passive method. 3. Splitting the tendon of a healthy muscle and transplanting only a part into the tendon of a paralyzed muscle. Vulpius calls this the descending method and Hoffa calls it the active method. In suturing tendons together the quilt suture of Goldthwait has many advantages. 4. Attaching the tendons of trans-

planted active muscles directly to the periosteum was proposed by Drobnik and advocated by Lange. The last method is greatly to be preferred when possible, as the resulting bond of union secured by this means is much stronger and enduring. When the tendon to be transplanted is too short for periosteal attachment Lange's method of using strands of silk to elongate the tendon may be advantageously employed.

4. **Extrauterine Pregnancy.**—Vineberg removed the placenta in his case of extrauterine pregnancy by the following method: He first ligated the uterine and ovarian vessels on the free side, he then cut the uterus across at the level of the os internum without making any attempt to separate it from the mass to which it was most intimately united, and then ligated the uterine artery on the involved side. In this way he cut off the main blood supply before making the attempt to enucleate the enormous placental mass. As a result of this procedure, he was able to separate the placenta from its extensive attachments with comparatively slight hæmorrhage. Even with this preliminary ligation of the main blood vessels, the loss of blood was sufficient to depress the vital powers of the already exhausted patient to such an extent that intravenous saline infusion had to be resorted to twice during the operation.

5. **Prostatic Hypertrophy.**—Barnett, after reviewing the usual consequences of prostatic hypertrophy, concludes: (1) The general practitioner should be prepared at least to make a rectal examination of the prostate whenever symptoms point to that region, and if hypertrophic changes are found, and after careful treatment if the tumor does not diminish in size, surgical intervention should be advised and insisted upon. (2) If infection has not preceded catheter life, it is sure to follow. (3) Early prostatic operations are not dangerous; late ones are always dangerous, and frequently fatal. The general practitioner has the fate of the prostatic in his hands, either to guide him over his trouble, or to advise him to continue a life of miserable suffering which intensifies itself toward the end. (4) We are examining old rather than young men, for prostatic enlargement, and in so doing, are getting the big rather than the little end of the dilemma.

6. **Enterostomy.**—Long gives the following as the most important measures accomplished by enterostomy: (1) Drainage of gas and fæces from the intestines. (2) In mechanical obstruction, relief of the distention, pain, vomiting, and toxæmia. (3) In septic conditions, depletion of the inflamed bowel and peritonæum; also the intestinal paralysis and sepsis are overcome. (4) Protection to the peritonæum, as in typhoid perforation. (5) Nourishment to the patient by making an artificial mouth. From this he concludes: (1) Enterostomy is always a life saving measure, never an operation of choice. (2) Enterostomy is not indicated when a more ideal surgical procedure is feasible. (3) In the hands of an experienced, carefully trained abdominal surgeon, ca-

pable of dealing with grave emergencies, an enterostomy is rarely resorted to; but the better the surgeon, the more quickly will he adopt any measure that will save his patient. (4) Every abdominal surgeon, according to the abundance of his material, must find cases in which only an enterostomy can with propriety be done. (5) When an enterostomy is indicated, to hesitate is to lose your patient; to operate promptly, dextrously, and with celerity means to tide your patient over the imminent peril and spare him for future consideration. Eight personal cases are reported.

MEDICAL RECORD.

April 8, 1905.

1. The Treatment of Pyelitis, By HOWARD A. KELLY.
2. Ætiology of Enlarged Prostate, By L. BOLTON BANGS.
3. Microscopical Examination of the Fasting Stomach Contents and Its Diagnostic Value, By WILLIAM ACKERMAN and LOUIS M. GOMPERTZ.
4. Acute Cholecystitis in the Puerperium. Report of Two Cases. Cholecystotomy. Recovery, By HIRAM N. VINEBERG.
5. Conservative Treatment of Protracted Cases of Acute Otitis Media Purulenta, with Its Complications, By ALFRED WIENER.
6. A Modification of the Heller Test for Albumin in the Urine, By ABBOTT SMITH PAYN.

1. **Pyelitis.**—Kelly reviews the general subject of pyelitis and illustrates the principal types of the affection by means of short histories of personal cases. He emphasizes the fact that mild types of pyelitis are not infrequent, and that if they are unrecognized or improperly treated they may lead to very serious consequences. The practical deductions to be drawn from the paper are: (1) It is important to take cognizance of a pyelitis of any grade whatever, as it may, at any time, become a menace to the functional value of the kidney, or even to life itself. (2) The severer grades of the affection are often the sequelæ of a milder pyelitis of long standing. (3) The first step in the investigation is to determine the extent of the affection by estimating the amount of pus in the urine and the relative number of organisms. (4) It is important to determine the cause of the infection, which is often of a mechanical nature, and therefore easily relieved. (5) By removing the cause, the disease may either be cured, or be so far benefited that a subsequent complete relief by means of local treatments is easily brought about. (6) The milder forms are best treated by rest, abundant water, and urotropin. (7) If there is not a speedy improvement, the next simplest plan of treatment is the catheterization of the kidney every two to four days for the purpose of evacuation, distention of the pelvis, irrigation, and instillation. Boric acid and nitrate of silver are the best drugs in this connection. (8) Improvement should be measured by the disappearance of pus from the urine and the diminution in the organisms, taking, say, three platinum loops as the measure in conveying the infected urine to the agar. (9) A patient improved, but not cured (complete absence of bacteria), should be watched

in the intervals of treatment, and guarded with especial care in case of any intercurrent disease. Should such a disease supervene, urotropin is a good prophylactic. (10) The severer forms of the disease may be treated by irrigation, which often brings great temporary relief. As a rule, however, the kidney must be opened and drained; if it has been extensively diseased, it should be removed.

2. **Enlarged Prostate.**—Bangs asserts that the theory that inflammation is the cause of enlargement of the prostate is the one to which he gives adherence. Gonorrhœa may be a factor in some cases of enlarged prostate, but in most cases other factors are of more importance. According to the author, masturbation, coitus reservatus, or coitus interruptus, and in general sexual excitation without normal satisfaction, must be regarded as the chief ætiological factors of prostatic hypertrophy. The following prophylactic rules should therefore be observed: (1) Sexual instruction in boyhood; (2) chastity in youth; (3) sexual restraint in early manhood, and (4) physiological sexual relations in the married state.

3. **The Stomach Contents.**—Ackerman and Gompertz assert that with the aid of the microscope alone it is possible to reach a correct diagnosis in the majority of stomach affections. They give in detail their method of conducting an examination and illustrate the microscopical appearance of the chief objects of diagnostic significance which are to be specially noted. They claim that: (1) The presence or absence of hydrochloric acid can be determined by a microscopical examination of the fasting stomach contents. (2) The origin of mucus can be determined only by a microscopical examination. (3) By the microscopical examination, mild cases of pyloric stenosis can be differentiated from simple gastrosuccorhœa. (4) Constant presence of pus, blood; and possibly infusoria in the fasting stomach contents is absolute evidence of extrapyloric carcinoma. (5) Benign obstruction can be diagnosed early by the finding of sarcinæ, yeast cells in chains, or food remnants. (6) The early diagnosis of malignant obstruction of the pylorus can be made by the finding of the Oppler-Boas bacilli.

4. **Cholecystitis.**—Vineberg thinks it is strange that so few cases of acute cholecystitis, as complications of the puerperium, have been placed on record. A careful search of the literature for the past ten years brought to light only four cases. Both the cases reported by the author were seen in consultation, and in both the attending physician had made a diagnosis of puerperal sepsis.

6. Premenstrual Pregnancy in a Girl Aged Thirteen Years, By A. W. ADDINSELL.
7. A Case of Chronic Intestinal Obstruction with Perforation of the Sigmoid Flexure, By G. A. CLARKSON.

2. **Shock and Collapse.**—Mummery, in his second Hunterian lecture, states that the degree of shock produced by an operation is dependent upon the amount of traumatism to the nerve elements of the part operated upon. Traction upon or injury to important nerves, and injury to parts richly supplied with nerve endings, such as crushing of the feet and hands, are very liable to cause shock. Of all injuries, burns and scalds involving a large area are most frequently followed by shock; burns of the second and third degrees more often cause death from shock than those of the third and fourth degrees, because in the latter the nerve endings are destroyed and can no longer send impulses to the nerve centres. The first effect upon the blood pressure by injury is a rise, followed later by a fall if the injury is continued. There may be an initial fall if the injury is severe. In abdominal operations the degree of shock depends upon the area of peritonæum exposed and the duration of the exposure. Any form of manipulation of the peritonæum causes a fall in blood pressure. Turning the intestines out of the abdomen is always followed by a sudden and dangerous fall in blood pressure. In elderly patients a very high initial blood pressure is generally observed, largely accounted for by arteriosclerosis. A relatively slight fall of blood pressure in such patients may cause shock. Shock is the chief risk of severe operations in children, due to the fact that the blood pressure is not sustained nearly so long as in adults. Children have no special liability to shock—the question is one of time. Ether anaesthesia almost always causes a rise in blood pressure, which elevation is usually maintained. Chloroform anaesthesia, on the other hand, is usually accompanied by a fall in blood pressure during the whole period of anaesthesia; it seems as if chloroform has a direct toxic influence upon the vasomotor centres, and that bad effects, due to its use, are due to such influence rather than to toxic effects upon the respiratory or cardiac centres. The author believes that the so called gas-ether-chloroform sequence for long operations is a mistake, and that the chloroform-ether mixture is certainly the best from the point of view of subsequent shock. Symptoms of shock frequently do not show themselves until some time after an operation. The condition of the patient prior to operation is an important factor, persons in relatively vigorous health being less liable to shock. The changes in temperature which occur are probably entirely secondary to the deficient circulation resulting from the fall in blood pressure. All the secretions of the body are arrested or markedly decreased; the intense thirst is due to absence of saliva and to the call of the tissues for fluid. Diabetes may follow shock, no matter how

produced. There is usually no loss of consciousness. The most popular means of treating shock hitherto has been by means of stimulants, but the author is opposed to their use. Strychnine may contribute to the fatal result by stimulating the exhausted vasomotor centres and so preventing their recovery. Digitalis is of but little value in shock. The methods of treatment to be recommended are those which mechanically raise the blood pressure. Position has a marked influence, the best being with the foot of the bed raised and the patient's head lower than his buttocks. Simple manual pressure upon the abdomen will raise the blood pressure in all conditions of shock and collapse, by driving the blood out of the splanchnic area. A tight abdominal binder acts in the same way, and is very simple and effective. The raising of the external air pressure, and so substituting an artificial peripheral resistance for the lost peripheral resistance caused by the exhaustion of the vasomotor centres promises to be the most effectual method of treating shock. Unfortunately it is not, as yet, a practical method.

4. **Pleuritic Effusion.**—West discusses the treatment of serous effusion, empyema, and pneumothorax by paracentesis and incision. In cases of serous effusion where the pleura is full of fluid, and the respiratory movements are abolished, the sooner paracentesis is performed the better. Even a small effusion is better tapped if it has existed for some time and shows no signs of disappearance. The duration of the pleurisy is not shortened by tapping; the temperature remains high and continues raised until the inflammation comes to a standstill. Dyspnoea coming on suddenly is of grave significance and calls for immediate paracentesis, being the result of functional breakdown or incompetence. There are no indications against paracentesis; the temperature is unaffected, and there is practically no risk of the conversion of the effusion from serum to pus. The best method is by siphonage—the aspirator should not be employed, for it may cause the lung to rupture and so produce pneumothorax or pyopneumothorax. A general anaesthetic is unnecessary. Free incision for refractory serous effusion is rarely required. It necessarily leads to empyema, but this is easier to cure than the recurrent serous effusion. Empyema should be treated by free incision. A needle should always be passed first, and when pus has been found, used as a guide for the knife. The best seat of incision is just in front of the postaxillary border and on the transverse level of the nipple. Resection of rib should not be performed as a matter of routine. If free drainage can be obtained without it, it is not necessary. There is no risk in washing out the pleura, and it should be done wherever the pus is curdy, flaky, or offensive. The mode of cure of an empyema cavity is by expansion of the lung and falling in of the side. The tube should not be removed too soon, and the cavity should be examined with a probe every few days. Pyopneumothorax should in all cases be treated like empyema—the side being freely laid open and drained so soon as the presence of pus has been established.

1. **Joint Affections.**—Owen states that the family physician often makes mistakes in not recognizing early and treating promptly diseases of joints. He is too often satisfied with the use of arnica or iodine—two of the greatest impositions in the pharmacopœia. Wasting of the muscles which control the joint is an early and interesting sign of joint disease, but it can be clearly seen only when both sides of the body are seen at the same time. In the case of a fat child the eye alone may fail to make out the wasting; grasping the limb with the fingers will always demonstrate it. The sound side should always be examined first, in order to gain the patient's confidence. If the skin is not hot, if there is no bulging and no tenderness on pressure, then the trouble has quite passed off, and movements may be restored to the joint. But this must be done gradually. Inflammation of the shoulder is more apt to escape being found out than inflammation of other joints. A good evidence is that when the patient raises both arms to the level of the shoulder the angle of the scapula on the bad side begins to move with the humerus long before the other. When the disease is active, it will be well to protect the shoulder by moulding on a leather shield. In affections of the wrist there is always a great temptation to use the hand; in most cases therefore the hand should be fixed in a splint, preferably moulded of undressed leather. It is almost certain that when the joint of a child or young adult is the subject of a quiet lingering inflammation, the cause is a tuberculous affection; this is especially true when there is a history of tuberculosis in the family.

2. **Anthrax.**—Legge, in the third of his Milroy lectures, discusses anthrax in relation to the wool and worsted trades, to hides and skins, and to horsehair. Woollorter's disease, or internal anthrax, is certainly much less prevalent than formerly. This is due to the regulations requiring care in the opening of the bales and removal of the damaged wool or hair, fallen fleeces, etc. Further, none of the dangerous specified wools—alpaca, pelotage, Persian, camel's hair, and mohair—may be opened or sorted, except at a place where a constant draught of air maintained by a fan carries the dust away downwards. Cases are

now more frequent in the rooms where carding and combing processes are carried on. The most dangerous foreign wool at present is Persian, followed next by camel's hair. Steam sterilization, were it possible, would be the best method of disinfection of wool. More careful and thorough washing of the wool would be the next best thing. Of hides and skins, those from China are the most dangerous. It is doubtful if there is any way in which hides to be afterwards tanned could be effectively disinfected. There seems no reason for doubt that anthrax can be conveyed by completely tanned material. As regards horsehair steam disinfection is the only effective means of removing the danger from manipulation of dangerous horsehair; but even here, absolute reliance cannot be placed on the destruction of all anthrax spores. Steam cannot be used for white hair, as it turns it yellow.

3. **Diseases of the Nasopharynx.**—Paget suggests that the inside of the nose and back of the throat, like the teeth, are with succeeding generations and in the general order of things, tending to become ill developed and enfeebled. This is especially true among the poor inhabitants of great cities. And the development of postnasal catarrh, hypertrophic rhinitis, ozæna, and adenoids and polyps, is fostered by this degeneration. Crowded, irregular, and carious teeth; crowded and irregular air passages lined with a mucous membrane which is liable to general atrophy at puberty; crowded stores of lymphoid tissue which is liable to an irregular sort of hypertrophy—surely all three of these conditions may have a common origin in gradual change of type.

4. **Periamygdalar Abscess.**—Thomson states that while the operation for the evacuation of a periamygdalar abscess (quinsy) is simple, safe, and satisfactory, yet many surgeons complain that it is difficult to find the pus, and that the operation is dangerous. The pus never forms in the tonsil itself, but is always in the areolar tissue between the tonsil and the pharyngeal aponeurosis. Frequently it is met with posteriorly in the prolongation of the posterior faucial pillar. But in the majority of the cases—over ninety per cent.—the abscess forms above and in front of the tonsil. The tonsil frequently shows signs of lacunar amygdalitis, and may be raised from its bed. Left alone the abscess generally bursts spontaneously into the mouth, the site of rupture often escaping detection. The site of election for opening the abscess is just external to the intersection of an imaginary horizontal line across the base of the uvula and another vertically along the anterior faucial pillar. The best instrument with which to open the cavity is a pair of Lister's sinus forceps—the blades being readily forced into the cavity, then opened widely and withdrawn—thus producing a vertical opening through which the pus escapes into the mouth. There is no risk of wounding a large vessel, and the patient more readily permits the operation. Pus may frequently be found as early as the third day. The writer has only failed once to open a quinsy by this method.

8. **Anæsthesia and the Kidneys.**—Thompson's

experiments on animals show that when anæsthesia is induced by ether and chloroform, the early effect is usually an increase in the secretion of urine, lasting up to the period of complete insensibility. But during full anæsthesia, however prolonged, the secretion of urine is almost completely arrested. By full anæsthesia is meant a degree just beyond the loss of conjunctival reflex. Upon removal of the anæsthetic the kidneys rapidly recover.

Proceedings of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of March 1, 1905.

The President, Dr. ARTHUR V. MEIGS, in the chair.

The Relief of Uræmic Hemiplegia and Other Uræmic States by Lowering Intracranial Pressure was the subject of a paper by Dr. ROBERT N. WILLSON.

The Famous Controversy Concerning the Internal Use of Cantharides was the title of a paper by Dr. T. L. COLEY.

Gallstone Obstruction of the Bowel; Report of a Case; Removal of the Stone by Operation; Recovery.—Dr. ALFRED C. WOOD reported the case of a woman, aged fifty-eight years, who was admitted to the University Hospital for obstruction of the bowel of five days' duration, with pain in the abdomen and vomiting. This was preceded by diarrhœa, lasting a week. For three months prior to this the patient had alternating periods of constipation and diarrhœa, lasting three or four days. The only other illness having any possible connection with the case occurred eight months before her admission to the hospital. At this time she complained of pain in the chest, the attack being called pleurisy. All purgatives administered by the mouth were promptly vomited, and enemata were ineffectual. An operation was performed for the relief of the obstruction, and a gallstone found, completely filling the lumen of the ileum about six inches from the ileocæcal valve. This was removed by incising the bowel and the wound closed with Lembert sutures. As the stone was faceted at either end, an examination was made to determine if any others remained in the body. When the hand was passed through the abdominal incision to the region of the gall bladder, another calculus could be felt in a mass of adhesions. The first incision was then closed with sutures, and a second made over the region of the gall bladder. In the centre of a mass uniting the pylorus, liver, gall bladder, and ducts another stone was found and removed. This wound was drained with gauze. The patient made a good recovery, being able to leave the hospital six weeks after the operation. The wound had closed one week previously.

Dr. J. ALLISON SCOTT reported the removal of a gallstone two inches long and an inch thick from the duodenum with a suppurative condition for six or eight inches on either side, in the case of a woman over sixty years of age. The bowel was resected and the woman died. He regarded the

intermittent attacks of pain as having important diagnostic significance. He had found in literature reports of two cases of aged women whose gallstones had been made to pass by the administration of half a pound of metallic mercury.

Dr. JOHN B. ROBERTS referred to a case in which he had removed a large intestinal calculus, two inches and a half long, from a woman who had been suffering many years with the symptoms presented in Dr. Wood's case. There were evidences of old adhesions in the region of the liver, and the stone was covered with intestinal concretions. In the case of another patient a stone, an inch and a half long, was passed after an attack of severe pain.

The Gardener's Spade Deformity and the Silver Fork Deformity in Fractures of the Carpal End of the Radius.—Dr. JOHN B. ROBERTS said that these lesions continued to be badly treated by a great number of practitioners, and that it seemed impossible to convince the profession that restitution of the normal concavity of the palmar surface of the lower part of the radius was essential for comfortable convalescence and perfect cure. This must be accomplished, even if great force was required to disentangle the fragments and thrust the lower piece into its normal relation with the upper one.

The so called "silver fork deformity" of the fracture, with displacement of the carpal fragment backward must be absolutely overcome before the fragments could be assumed to have been properly coaptated. Fracture in the same part of the radius with displacement in the opposite direction, namely, forward, was frequently unrecognized, and was therefore imperfectly reduced. In this fracture the general deformity, which Dr. Roberts called the "gardener's spade deformity," was very characteristic. It was very different from the "silver fork deformity," with backward displacement of the carpal piece. The planes of the forearm and hand were related to each other almost exactly as were the planes of the handle and blade of the gardener's spade. In both lesions the styloid process of the radius was apt to be carried upward toward the elbow. As a result, an imaginary line joining the ulnar and radial styloid processes crossed the axis of the forearm at nearly a right angle or with the radial end nearer the elbow than the ulnar end. In the normal arm this interstyloid line was farther from the elbow on the radial than on the ulnar side. The ulnar head was very prominent at the back of the wrist in fracture with forward displacement, but not so in the break with backward displacement. In both forms of injury, however, this ulnar head might be very prominent at the ulnar edge of the wrist, because the shortening of the broken radius might give a displacement of the hand and carpus toward the radial side of the limb. Examination with the x ray Dr. Roberts believed to be of aid in diagnosis, though usually it was not needed. The treatment of both fractures was easy, if the surgeon would only use force enough to disentangle the carpal end and compel it to assume its normal position. A light straight splint on the dorsum of the forearm and hand, or a convex splint on the palmar

surface, was usually the proper retentive dressing after reduction had been thoroughly accomplished.

Dr. ALFRED C. WOOD agreed fully with Dr. Roberts that the fracture under discussion was one of the most badly treated of all fractures. He believed that in the large majority of cases the shaft was impacted in the lower fragment. He approved of giving an anæsthetic to secure reduction when there was much deformity.

Dr. FRANK WOODBURY referred to the inability at first to give a true prognosis, owing to the possibility of comminution of the lower fragment and of the presence of synovitis. He called attention to the recommendation of Dr. Thomas G. Morton to make frequent examinations of fractures, especially of the radius, and as to the application of hot douching and massage. In the cases he had treated he had not made special effort to reduce the fracture completely at the beginning, but had relied on the later manipulations, and had had satisfactory results.

Book Notices.

Transactions of the American Dermatological Association at its Twenty-eighth Annual Meeting. Official Report of the Proceedings, by CHARLES J. WHITE, M. D., Secretary. Pp. 204.

The volume opens with the address of the president, Dr. Joseph Zeisler, of Chicago, who suggests a change of the time of year for holding the meetings from the close of spring or the beginning of summer to the Christmas holidays or to a late date in September, before the opening of the college courses. He seems to have been led to this suggestion by having observed that many of the members had shown a proneness to presenting their papers before the dermatological section of the American Medical Association. We are inclined to think that the president's suggestion is well founded. It is true that those who elect to appear before a section of the enormous national organization get a larger audience, but the discussion of their papers is undoubtedly far inferior to that which might be looked for in the special association. The president also betrays some impatience of the plan of meeting in Washington every three years, in connection with the Congress of American Physicians and Surgeons, "on account of the absence of clinical material there," but that point does not seem to us so well taken. The association has generally met in places where there is a dearth of such material, and surely there can be little advantage in converting an annual meeting into a clinic.

Almost the whole of the remainder of the volume is taken up with the formal papers presented at the meeting, with condensed reports of the discussions. In the appended matter there is a valuable table showing the reported prevalence of numerous skin diseases in various American cities during the year 1903. The volume is copiously illustrated with excellent half tone pictures. It is a valuable addition to the literature of dermatology.

Miscellany.

A Japanese Emergency Hospital.—Mr. George Kennan, in his story of Port Arthur in the *Outlook*, for March 11, 1905, thus describes the arrival of wounded Japanese from the front and their reception at an emergency hospital:

The arrangements for their reception were everything that could be desired. Several hundred Chinese stretcher bearers and ambulance men were waiting for them at the station, and those who could not walk were carried up out of the railway cut to a series of large closed sheds, where they were promptly examined by a corps of Red Cross surgeons, and furnished, when necessary, with hot food from a neighboring kitchen. Every man brought with him, from the field hospital at the front where he had been treated, not only his identification tag, but a complete medical record of his case. The surgeons in the sheds read these papers, examined the patients, decided what should be done with them, made additional notes on the records, and, after giving them time for rest and refreshment, sent them to steamers lying at the piers, or to one of the forwarding hospitals in the city. The slightly wounded and convalescent sick went directly to Japan, while the more serious cases were held in Dalny for further treatment. Everything was done with perfect order and system, and in half or three quarters of an hour after the arrival of the train the sheds were empty and all the men were either in hospital or on their way home. In order to get room for new arrivals from Port Arthur and the north, the resident surgeons made a partial clearance of the Dalny hospitals every day, by sending to Japan all patients who were able to stand the sea voyage. Half a dozen Red Cross steamers were constantly going back and forth, and every one of the larger transports, such as the *Tosa-maru* and the *Aki-maru*, had accommodations for wounded, and carried a regular staff of thirty surgeons and nurses. When, therefore, a man reached Dalny, he had no more severe hardships to anticipate. It is unnecessary, perhaps, to compare the treatment of Japanese sick and wounded with that received by our soldiers in eastern Cuba and on some of the transports that brought them home; but we may profitably think about the matter and take notes. The bringing of disabled men in open flat cars from Liao-Yang to Dalny is bad, and causes unnecessary sufferings; but it must not be forgotten that the Japanese had to change the gauge of two hundred and fifty miles of road, and import all the rolling stock for it from Japan, while at the same time they were carrying on a great war and sending to the front provisions and ammunition for an army of two or three hundred thousand men. It was virtually impossible, in such circumstances, to equip the railway with hospital trains, and they had to do the best they could with freight cars. If fighting continues in the north through the winter, the transportation of wounded from Liao-Yang to Dalny in open flat cars may become impracticable, on account of the severity of the Man-

churian climate; but the soldiers at the front have been abundantly supplied with warm clothing, and by the time the cold becomes intense the Japanese will probably have brought over closed cars enough to make up two or three ambulance trains, warmed by hibachis or sheet iron stoves. Meanwhile their facilities for treating and transporting the wounded seem to be fully adequate, and although they have sometimes had to handle as many as twelve thousand disabled men in a week, they have never been overwhelmed. At a single bandaging station I have known them to pick up and give first aid to two thousand wounded men in eight hours.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from March 21 to April 1, 1905:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Florida—Jacksonville	Mar. 18-25.	3	
Florida—West Tampa	Mar. 18-25.	5	
Illinois—Chicago	Mar. 18-25.	18	2
Illinois—Danville	Mar. 21-25.	7	4
Louisiana—New Orleans	Mar. 18-25.	16	
Four imported.			
Michigan—Detroit	Mar. 18-25.	1	
Missouri—St. Louis	Mar. 18-25.	35	4
Nebraska—Omaha	Mar. 18-25.	1	
Nebraska—South Omaha	Mar. 18-25.	1	
Pennsylvania—Philadelphia	Mar. 18-25.	1	
Pennsylvania—Steelton	Mar. 18-25.	1	
South Carolina—Charleston	Mar. 11-25.	6	1
South Carolina—Greenville	Mar. 11-25.	4	3
Tennessee—Memphis	Mar. 18-25.	11	
Tennessee—Nashville	Mar. 18-25.	2	

Smallpox—Insular.

Philippine Islands—Manila	Jan. 28-Feb. 11.	2

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending April 5, 1905:

BAILEY, C. W., Acting Assistant Surgeon. Granted leave of absence for four days from April 10th.

BEAN, L. C., Acting Assistant Surgeon. Granted leave of absence for two days.

BILLINGS, W. C., Passed Assistant Surgeon. Granted leave of absence for one day, March 23rd.

BILLINGS, W. C., Passed Assistant Surgeon. Granted leave of absence for six days from April 5th.

BROWN, B. J., JR., Acting Assistant Surgeon. Granted leave of absence for two days from April 4th.

COLLINS, G. L., Assistant Surgeon. Granted leave of absence for seven days from March 31, 1905, under paragraph 191 of the regulations. Granted five days' extension of leave of absence from April 6th.

GODFREY, JOHN, Surgeon. Granted leave of absence for one month from April 15th.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for four days from March 29th, under paragraph 210 of the regulations.

MAGRUDER, G. M., Surgeon. Relieved from duty at Cincinnati, Ohio, and directed to proceed to San Francisco, Cal., assuming command of the service, and relieving Passed Assistant Surgeon W. G. Stimpson.

MCCORMAC, J. T., Acting Assistant Surgeon. Granted leave of absence for five days from April 4th.

NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for one day, March 6, 1905.

PARKER, H. B., Passed Assistant Surgeon. Granted leave of absence for six days from April 2, 1905, under paragraph 191 of the regulations.

ROBINSON, D. E., Passed Assistant Surgeon. Upon the arrival at Port Townsend, Wash., of Passed Assistant Surgeon W. G. Stimpson, to report to him for duty and assignment to quarters.

STEVENSON, J. W., Acting Assistant Surgeon. To assume temporary charge of the service at Cincinnati, Ohio. April 3, 1905. Granted leave of absence for thirty days, on account of sickness, from February 27th.

STIMPSON, W. G., Passed Assistant Surgeon. Upon being relieved at San Francisco, Cal., by Surgeon G. M. Magruder, to proceed to Port Townsend, Wash., assuming command of the service, and relieving Passed Assistant Surgeon D. E. Robinson.

WARREN, B. S., Assistant Surgeon. Granted leave of absence for four days from April 3rd.

WALKER, R. T., Acting Assistant Surgeon. Granted leave of absence for twenty days from March 30th.

YOUNG, G. B., Passed Assistant Surgeon. Detailed to represent the service at the meeting of the Council on Medical Education of the American Medical Association at Chicago, Ill., April 20th.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending April 8, 1905:

CLIFFORD A. B., Assistant Surgeon. Detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the Navy Yard, New York, N. Y.

COWAN, J., Pharmacist, retired. Ordered to the Naval Recruiting Station, New York, N. Y.

DESSEZ, P. T., Assistant Surgeon. Detached from the *Kentucky* and ordered to the Naval Hospital, Norfolk, Va., for treatment.

FARWELL, W. G., Medical Director. Retired from active service in accordance with the provisions of Section 1444, Revised Statutes, April 5, 1905, upon which day he will have reached the aged of sixty-two years.

FIELD, J. G., Surgeon. Appointed a surgeon in the United States Navy from March 3, 1905.

FITTS, H. B., Surgeon. Detached from the *Buffalo*, when placed out of commission, and ordered to the *Lawton*.

FREEMAN, G. F., Passed Assistant Surgeon. Ordered to the Naval Station, Olongapo, P. I.

GUTHRIE, J. A., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from January 1, 1905.

MILLER, J., JR., Assistant Surgeon. Detached from the

Buffalo when placed out of commission and ordered to the *Lawton*.

ORVIS, R. T., Surgeon. Commissioned surgeon, with the rank of lieutenant commander, from January 1, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending April 8, 1905:

ADAIR, GEORGE W., Lieutenant Colonel and Deputy Surgeon General. Left St. Paul, Minn., on thirty days' leave of absence.

BIRMINGHAM, H. P., Major and Surgeon. Ordered to make medical and sanitary inspection at Forts Clark and Bliss, Texas, Forts Sill and Reno, Oklahoma Territory, and Fort Logan H. Roots, Arkansas.

CARTER, EDWARD C., Major and Surgeon. Relieved from further duty at Fort Yellowstone, Wyoming, and ordered to Fort Brady, Michigan, for duty.

EDIE, GUY, L., Major and Surgeon. Ordered to report to the Secretary of War for duty as attending surgeon to accompany him to the Philippine Islands and return to this city.

FRICK, E. B., Major and Surgeon. Ordered to take charge of the Chief Surgeon's Office, Department of Dakota, during the chief surgeon's absence on leave.

GIRARD, A. C., Assistant Surgeon General and Brigadier General. Appointed a brigadier general, to rank from April 6, 1905.

KULP, JOHN S., Captain and Assistant Surgeon. Relieved from duty in the Department of California, and ordered to the Philippine Islands for duty, to sail on transport, April 30, 1905.

MANLY, C. J., Captain and Assistant Surgeon. Relieved from duty at Fort Brady, Mich., and ordered to Fort Yellowstone, Wyoming, for duty.

MAUS, L. M., Lieutenant Colonel and Deputy Surgeon General. Relieved from duty at Fort Riley, Kansas, and ordered to San Antonio, Texas, for duty as chief surgeon of that department.

ROCKHILL, E. P., First Lieutenant and Assistant Surgeon. Granted thirty days' sick leave of absence, with permission to apply for thirty days' extension.

USHER, F. M. C., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Yellowstone, Wyoming, and ordered to Fort Brady, Michigan, for duty.

WELLS, GEORGE M., Major and Surgeon. Retired from active service.

Births, Marriages, and Deaths.

Born.

DEAN.—In Chicago, Illinois, on Friday, March 24th, to Dr. Elmer A. Dean, United States Army, and Mrs. Dean, a daughter.

Married.

HOUGHTON—WHITAKER.—In Philadelphia, on Saturday, March 18th, Dr. Charles W. Houghton and Mrs. Sarah J. Whitaker.

WILKENS—BEATIN.—In Philadelphia, on Tuesday, March 28th, Dr. George L. Wilkens and Miss Annie Beatin.

Died.

DREWRY.—In Mineola, Virginia, on Monday, April 3rd, Dr. Samuel D. Drewry, in the seventy-fourth year of his age.

GILBERT.—In Liberty, N. Y., on Wednesday, March 29th, Dr. Thompson D. Gilbert, in the thirtieth year of his age.

HADEL.—In Baltimore, Maryland, on Tuesday, April 4th, Dr. Albert Kimberly Hadel, in the fifty-fifth year of his age.

SAUERBRIE.—In Clarksville, N. Y., on Sunday, April 2nd, Dr. Fred Sauerbrie.

Original Communications.

THE VALUE OF THE RADIOGRAPH IN DIAGNOSIS.*

By SINCLAIR TOUSEY, A. M., M. D.,

NEW YORK,

SURGEON TO ST. BARTHOLOMEW'S CLINIC.

The first case is that of W. R. D., a man aged 22 years, a patient at St. Bartholomew's Clinic. There was a congenital deformity of both feet which had become so exaggerated as to cripple him and necessitate the wearing of shoes of a very awkward shape. A radiograph (Fig. 1) showed the phalanges of the great toes to be at a right angle to the metatarsals. The case interested me from the standpoint of an x ray specialist, and the radiographs made at different stages were very helpful in the treatment of the condition. I operated on the left foot in May, 1904; a dorsal incision being made over the metatarsophalangeal articulation, and a cuneiform osteotomy being done, as indicated by the black lines. This removed the greater part of the head of the

metatarsal bone by two cuts with the chisel, one transverse to the long axis of the bone just behind the articular surface, and one almost at right angles with the first, removing a wedge which included nearly, but not quite, all of the articular extremity of the metatarsal bone. The phalanx was not touched. Fig. 2 shows the condition after operation on the left foot and before operation on right foot. Figs. 3 and 4 show the present condition of both feet. This is five months after the last operation; both great toes are straight and there is the normal mobility at the metatarsophalangeal articulations. In this connection the accompanying skiagraph (Fig. 5) of a practically normal foot may prove of interest. In all these radiographs a sesamoid bone is visible and looks almost like an exostosis.

The patient with congenital injury to the shoulder is a boy, aged 7 years, with a story that when he was born the doctor took him by the left arm and threw him across the room. He has never been able to move his left arm since. Ordinary methods of examination showed complete ankylosis at the shoulder, the humerus moving only so far as the scapula could follow it, flattening of the shoulder without muscular atrophy, the point of the acromion apparently projecting about

* Read at a meeting of the Orthopaedic Section of the Academy of Medicine.

FIG. 1.—Bromide print radiograph of both feet before operation for hallux valgus.

FIG. 2.—Hallux valgus. Right foot before, left foot after operation.

FIG. 4.—Hallux valgus. Radiograph showing condition after operation on both feet.

an inch further than normal over the upper end of the humerus. The head of the humerus could not be felt, either in the glenoid cavity or anywhere else. The boy had good use of the arm through a limited radius of motion, and was able to climb trees, etc. The accompanying skiagraph shows the sound shoulder (Fig. 6) with its rounded outline formed by the head of the humerus and the upper extremity of the shaft of the humerus large and well developed. The other shoulder (Fig. 7), however, shows the upper part of the shaft of the humerus only two thirds the normal size, and perched upon its upper extremity is a little knob, of the size of a marble, which represents the head of the bone. The flattened contour of the shoulder is readily seen to be due to the absence of the rotundity of the humeral head. An indication of the ankylosis is seen in the skiagraph, where we notice that the spine of the scapula is tilted above the level of the clavicle when the arm is at the side. My diagnosis is congenital injury to the osteoplastic cartilage and consequent lack of development; my advice was not to attempt any surgical treatment.

FIG. 3.—Hallux valgus. Condition five months after operation on the second foot.

FIG. 5.—Radiograph of a normal foot.

FIG. 6.—Normal shoulder (case having congenital injury of the other shoulder).

Another radiograph which may be interesting in this connection illustrates the case of a young lady, with loss of function at the shoulder joint, upon whom thousands of dollars had been spent; for whom the efforts of the best orthopædists in this country and Europe had accomplished practically nothing. The history is too long for the present paper, but the fluoroscope showed at a glance that on the sound side the rounded head of the humerus and the glenoid cavity formed a natural ball and socket joint with almost unlimited range of motion, while on the affected side (Fig. 8) the flattened and irregular head of the humerus could not possibly form part of a joint with a normal range of motion. Here, too, my advice was to avoid surgical interference, to do everything possible to promote the nutrition of the atrophied muscles about the shoulder, and to prevent further morbid changes in the joint, for this was apparently an acquired condition.

FIG. 7.—Congenital epiphyseal separation of the head of the humerus.

FIG. 8.—Ankylosis at shoulder, the result of an anatomical change in the head of the humerus.

FIG. 9.—Seven months old fracture of the neck of the femur.

The third case which I am permitted to report is that of Miss L. C., aged 38 years, and weighing 140 pounds. She was brought to my office by Dr. R. W. Eastman and the history is briefly that the left hip was broken seven months before, that she was treated in a hospital chiefly by rest in bed and traction, that there is shortening of one and one half inches, and that she still has to walk with two crutches. On inspection the great trochanter was found to be very prominent beneath the glutei. The radiograph (Fig. 9) shows an intracapsular fracture of the neck of the femur with displacement upward, the head of the femur remaining in the acetabulum. There is no evidence of bony union having taken place.

Pictures like the last, of course, require the best apparatus and technics, but granted these conditions they are taken with such a short exposure as to be absolutely devoid of risk. This hip picture was made with a moderate current of only nine ampères, with the tube at a distance of 19 inches from the plate and an exposure of one hundred and fifty seconds in all.

One more radiograph (Fig. 10) may be of interest. This is of a man, Mr. T. F., weighing 175 pounds, brought to my office by Dr. Leroy Broun

to be examined for renal calculi. The exposure was for two minutes at a distance of 22 inches from the plate. The picture shows seven or eight large calculi, looking like a bunch of grapes, and will probably interest the members present to-night, because of the beautiful detail shown in the spinal articulations. Perhaps I ought to add that none of my pictures is ever touched up. They are all exactly as produced by exposure to the x ray.

103 WEST SEVENTY-SIXTH STREET.

HÆMATOMA OF THE VULVA AND THE VAGINA.

By I. L. HILL, M. D.,

NEW YORK,

CLINICAL INSTRUCTOR IN OBSTETRICS, CORNELL UNIVERSITY
MEDICAL COLLEGE.

Hæmatoma of the vulva and of the vagina was first described in 1554, by Rueff, of Zurich, in a short paragraph under the heading *Tumeur sanguine de la vulve et du vagin*. It was not mentioned again until one hundred and fifty years later, when it was briefly referred to by Philippe Peu. In

1734 it was made the subject of a thesis by Kronauer, of Bâle. The subject received attention at short intervals from this time on and during the hundred years following Baudelocque, Boer, Audibert, and Mme. La Chapelle contributed case reports, while Legouais and Siebenhaar added practical observations. In 1830 Deneux published a notable monograph on Thrombus of the Vulva. In American medical literature the subject was first treated independently by Dewees (*Phil. Med. Journal*, Nov., 1827). Velpeau, '34; H. Blot, '53; Cazeau, '56; Populus, '57; Scanzoni, '67; Elliott, '68; Hervieu, '70; Doléris, '83; Barker, '86; Mme. Sasonoff, '86; Cadillac, '94; Budin, '86 to '98, have all made important contributions.

Hæmatoma, which has been called variously thrombus of the vulva and the vagina, labial hæmatocele and pudendal hæmatocele, is a tumor due to an extravasation of blood into the connective tissue of the labia majora or of the vaginal wall. It extends frequently into the perinæum as far as the

FIG. 10.—Renal calculi, looking in the radiograph like a bunch of grapes. Beautiful detail in the spine.

anus and sometimes to the buttocks. In its extensions upward the extravasation may invade the subperitoneal tissue, even reaching the region of the diaphragm. The effusion of blood coagulates rapidly. Most frequently a globular tumor is formed, but, because of the greater resistance of certain tissues in the course of the invasion, hour glass shaped tumors or cylindrical tumors with fusiform proliferations are met with. A considerable œdema extending beyond the limits of the actual extravasation of blood adds to the deformity of the parts. The actual tumor varies in size from a hazel nut to a cricket ball or to a large canteloupe. One case has been reported with a diameter of 21 cm., and the case that the author presents was probably no less.

Hæmatoma is usually found at one side of the vagina, but it may extend beyond the median line and is sometimes bilateral. Sixty per cent. of all cases are of one labium primarily, twenty-five per cent. are vaginal, ten per cent. intrapelvic and five per cent. are of the labia of both sides.

Attempts have been made to classify hæmatomata according to the tissues chiefly invaded. Laborie has made an elaborate classification which cannot be taken seriously; for, as Budin says in discussing it, "the army of invasion does not respect the frontiers of the country invaded." Budin recognizes: 1st, hæmatomata of the labia; 2d, hæmatomata of the vaginal wall; 3d, pelviabdominal hæmatomata.

Anything that causes a stagnation of the local circulation is a predisposing cause, anything that endangers the integrity of the vessel walls may be an exciting cause of hæmatoma. The great vascularity of pregnancy and the varices are the chief predisposing causes, but that the predisposing causes are, after all, relatively unimportant is seen from the extreme rarity of the accident. External violence or muscular exertion in their various expressions are the exciting causes. In pregnancy it is the long walk or the strain of severe vomiting, in labor, manual or instrumental interference on the part of the accoucheur, or the straining of the patient. After labor, the hand of the operator removing the placenta may cause the rupture. But most frequently in cases occurring after labor the damage has been done during the expulsive act. The foetal body has then acted as a tampon. The pressure has stopped the hæmorrhage. Later some external force or the relaxation of the tissues has dislodged the guarding clot and the blood has poured into the tissues unimpeded.

An interesting feature is the frequent occurrence, of hæmatoma between the births of twins. The condition is brought about by the injuries received during the birth of the first child. The second child's delivery is often impeded by the tumor.

Dubois, in 14,000 cases, reports two hæmatomata, Hugenberger in the same number of births reports eleven cases. The author has personally encountered three cases. The consensus of opinion is with Mme. Sasonoff, who estimates one case for 2,500 labors. It is safe to assume that many cases of small size are overlooked or disregarded.

More than fifty per cent. of all cases, according to all observers, occur after delivery. Of the remainder only about ten per cent. occur before the second stage of labor and they are divided equally between the first stage and pregnancy.

Pain, sudden appearance of a tumor, and *hæmorrhage* are the cardinal symptoms of hæmatoma.

The pain varies in intensity. Sometimes it is slight, particularly directly after the passage of the foetal body, when the tissues are relaxed, and the pressure anaesthesia still exists. At first there is a pin prick sensation, then follow sharp pains radiating to the lumbar regions and thighs as the violent distention of the tissues takes place. After this, as the tissues become less sensitive from the prolonged pressure of the tumor, there is a feeling of extreme tension. Vesical and rectal tenesmus are present in all cases of considerable size.

The formation of tumor is very rapid. In the case of vulval tumors, the growth is perceptible to the eye. The tumor is glistening in appearance and dark blue, purple, or even black in color. Rectal or vaginal examination is difficult if the tumor is large. The vaginal tumors cannot at first be seen. Pain or tenesmus attracts attention and a vaginal examination determines the presence of the tumor. Lochial discharges are sometimes blocked by the hæmatoma. The walls of the tumor may remain intact or may rupture with the discharge of blood and clots, diminution of pain following.

While the tumor is usually very rapid in formation and attains its full development in a few hours, occasionally the increase is intermittent, clots alternately forming and being dislodged.

The simplest and happiest termination of hæmatoma is by resolution. Here, after coagulation, gradual contraction and diminution of the tumor follows until, after from three to six weeks, only a slightly indurated area marks its site. Rupture of the hæmatoma is frequent. It may occur during the formation of the tumor from excessive distention, from violence, or strain (especially during labor) or from thinning or necrosis of the sac. The amount of hæmorrhage following rupture varies. It may result fatally. Infection of the mass, with suppuration, was formerly a frequent termination, and many of the deaths reported by early observers were due to this complication. Under the present methods this termination is now infrequent.

The diagnosis of hæmatoma is generally easy. The

sudden appearance of the tumor and the rapid development of the train of pressure symptoms is characteristic. Abscess of a vulvovaginal gland might possibly be thought of, but the less rapid development would eliminate it. An unilateral œdema, if encountered, might on purely objective examination cause some confusion. Œdema is always present in vulval hæmatoma and in the presence of a local œdema, the absence of a small deep seated hæmatoma could not immediately be shown. Vaginolabial hernia would also have to be considered. Cystocele with distended bladder, which might be suggested by the vaginal form of hæmatoma, could readily be eliminated by the use of the catheter. Cases are reported in which the tumor has been mistaken variously for cyst of the vagina, retroversion, inverted uterus, and uterine polypus.

If we take an estimate from all cases of hæmatoma reported in medical literature, we will encounter a very high mortality. For example:

Deneux reports 66 cases, with 22 deaths.

Populus reports 34 cases, with 5 deaths.

Blot reports 19 cases, with 5 deaths.

In these cases we have a mortality of twenty-seven per cent. But we find that in fully half of these cases which occurred before the era of antiseptics, the cause of death was septicæmia. Mme. Sasonoff cites seventeen patients of whom seven died of hæmorrhage and ten of septic infection. We would expect to find a marked reduction in the number of cases terminating fatally from sepsis under the present methods. We are borne out in this by the report of Winckel. He submits a series of cases treated during the reign of antiseptics. The mortality in these cases was twelve per cent. and hæmorrhage was practically the sole cause of death. We must consider the occurrence of hæmatoma a grave event and hæmorrhage the chief source of danger.

Fortunately the largest number of cases occur after labor has been completed. When rupture occurs in such cases, we are confronted with a simple case of hæmorrhage which we can treat independently. But the appearance of a vaginal hæmatoma in the second stage of labor is a matter of greater gravity. The tumor if large causes a dystocia. Rupture is then inevitable. The pressure of the presenting part may bring this about. But frequently the operator elects to empty the tumor to deliver the child. Vaginal hæmatoma in the course of the expulsive stage of labor may be said to present dangers parallel to those of placenta prævia.

Treatment of hæmatoma must be expectant. Deneux outlined a system of prophylactic treatment in which he counseled among other preventive measures the puncturing of all varices in preg-

nancy. Inasmuch as the occurrence of hæmatoma is so rare that many textbooks of obstetrics do not even mention the subject, it would seem that such an extreme of prophylactic prudence would hardly meet with favor. Aside from the annoyance to the patient, it is even doubtful that the puncturing of varices in a thousand or more patients would not cause complications quite as serious in the total as the one case of hæmatoma we might expect in this number of cases.

Some authors have advised immediate use of the knife when a hæmatoma appears during pregnancy. As there is always the possibility of the fœtus passing without rupturing it, we may as well take the benefit of this chance. When the tumor first appears during the expulsive stage, we need not deviate from this policy unless unmistakable dystocia is produced.

In the largest class of cases hæmatoma appears after the birth of the child. The consensus of opinion among the most authoritative writers who have discussed this question is that the best results will follow a plan of treatment which favors the contraction or absorption of the tumor. If the hæmatoma is very large it is probable that pressure necrosis of the coverings of the blood mass will eventually allow a rupture. When this event seems imminent, the tumor should be generously incised. After incision the clots should be turned out, the bleeding points ligated, and the cavity irrigated with an antiseptic solution and packed with gauze. Up to the time that incising is indicated, ice, astringents, and pressure should be applied to favor contraction and absorption. The after-treatment of a hæmatoma which has been opened and packed consists of removing the packing, irrigating and packing again with a less quantity of gauze until the cavity has closed from the bottom. It is needless to say that there is occasion for intelligent general treatment of a patient suffering from hæmatoma. The conditions brought about by the hæmorrhage demand appropriate general treatment. Shock must be combated and elimination favored.

REPORT OF CASE.

Mrs. E., German, aged 22 years, para II. Previous history of no illness except diseases of childhood. First confinement normal. Weight of child first confinement, 7 pounds. Was delivered of second child November 2, 1902; labor precipitate. The attendant was summoned when the first pains were felt, but on his arrival fifteen minutes later the child was already born. Weight of child, 9 pounds. Circumferences: Occipitomental, 15 $\frac{3}{4}$ inches; suboccipitobregmatic, 12 inches; biparietal, 12 $\frac{3}{4}$ inches.

The third stage was completed without assistance twenty minutes after the birth of the child. Weight of placenta, 1 $\frac{1}{2}$ pounds. Size, 6 inches by 7 inches.

No anomalies. There was no bleeding after the third stage was complete from the uterus, cervix, vagina, or perineum. The uterus was firmly contracted. A vaginal douche, mercury bichloride 1 to 6,000, was given and fluid extract of ergot, 1 drachm, was administered. An abdominal binder was applied and the vulva dressed. Patient's temperature was 99, pulse 68.

Six hours later the attendant was hurriedly called to the case. The patient reported that she had suddenly felt a sharp pain in the vulva. This had been followed by a painful feeling of pressure. She felt faint and nauseated. Temperature was 100, pulse, 140. On inspection, an enormous hæmatoma of the vulva was found. The external circumference was much greater than a foetal head. The parts were distorted. The tumor, which had its origin on the left side, drew upon all the surrounding tissues for its coverings. The upper and inner quadrant of the presenting sphere was covered with the greatly stretched vaginal wall; the outer portion drew upon the superficial integuments as far as the thigh. The tumor seemed to merge into the thigh itself. Below, the perineum was involved. The anus gaped widely and for an area of over two square inches the rectal tissues formed the external covering of the sphere. The globe was glistening and the color purple, the anal and vaginal portions almost black. The surrounding tissues were œdematous. The œdema extended above, beyond the pubes, externally midway down the thigh, and behind into the buttocks. The right labium was also involved in the œdema. The tumor was uniformly tense and hard. The surrounding tissues were tense but boggy on pressure. A finger was passed with great difficulty into the vagina by pressing firmly against the right vaginal wall. The entire vagina was occluded. The finger could not be passed into the rectum, as the sphincters were already stretched to the point of endurance. A probe passed into the rectum showed that the passage was completely plugged and that the tumor filled the pelvis below. There was no external bleeding. The patient was in a state of profound shock. Immediately general treatment for hæmorrhage was insti-

tuted. Externally an astringent, antiseptic, wet dressing was applied and covered with an ice pack. With much difficulty the patient was catheterized. Saline cathartics were given. A soft catheter was passed into the rectum and saline enemata were given. After twenty-four hours the patient's general condition was fair. Temperature, 100.6°; pulse, 120. The œdema had subsided somewhat and the tumor decreased considerably in size. At this time the photograph which is reproduced here was taken. There were some fluctuating places on the tumor.

On the third day there was a slight decrease in the size of the tumor, but pressure necrosis had begun near the sphincters and at several other points. It was apparent that the mass would rupture spontaneously. With careful aseptic precautions, a vertical incision five inches long was made at the juncture of the vaginal mucous membrane and the skin of the external genitalia. Huge clots, a pint and a half in the aggregate, were removed. There were no bleeding points of consequence, but there was some oozing. The cavity was irrigated with mercury bichloride solution and packed with sterile gauze. The day following the patient's temperature was 100.6°; pulse, 116. The packing was removed. There was very little oozing. The cavity was irrigated with a hot antiseptic solution and the packing was reinserted, less compactly than before.

This treatment was carried on for ten days, the packing being decreased in quantity, day by day, until on the tenth day it was little more than a small gauze drainage. After four weeks the patient had fully recovered. The child had been placed with a wet nurse and was in excellent health. No secretion of milk had appeared in the mother's breasts, although she had had an abundant supply in her first parturition.

The patient was examined by the author a short time ago and bore no noteworthy evidences of her trouble.

THE SYMPTOMATOLOGY AND DIAGNOSIS OF ATYPICAL FORMS OF PNEUMONIA.*

By J. C. WILSON, M. D.,

PHILADELPHIA.

The term pneumonia, signifying an inflammation of the lungs, is generally applied both clinically and pathologically to two essentially dissimilar conditions—bronchopneumonia and croupous pneumonia. This nosological error is the more unfortunate since it not rarely happens that cases of the one form of pneumonia bear clinically a more or less superficial resemblance to the other form and even upon the post mortem table there are, though much more rarely, cases in which a similar superficial resemblance of the lesions of the two forms may be observed. Nor does the use of the terms lobular and lobar pneumonia greatly simplify the matter, for there are cases of bronchopneumonia in which the pulmonary lesions involve the whole of large masses of lung tissue or even an entire lobe on the one hand, while upon the other there are cases of croupous pneumonia in which the lesions are limited, circumscribed, or even lobular. But those are exceptional.

There is abundant reason to believe that a failure on the part of practitioners to discriminate between these two essentially distinct diseases known as pneumonia, even in cases in which the diagnosis is obvious, has been the cause of misleading therapeutic conclusions and rendered much of the statistical data relating to the morbidity and mortality of croupous pneumonia absolutely worthless. It is to be hoped that the clearer and more precise modern methods on the part of the teachers alike of clinical medicine and of pathology will lead to a more general recognition of the fact that in practice we have to deal daily and side by side with a local inflammatory process and a constitutional infection with a local pulmonary exudate, both of which we call pneumonia, and to differentiate them by the use of the proper qualifying adjectives bronchial and croupous. Then, and not until then, will there be value in the statistics.

Words are the tools of thought and to those who make the distinction referred to habitually and as accurately as circumstances permit the classification of the observed facts is comparatively easy and an intelligent scheme of the various forms of pneumonia is possible. To those, however, who fail to make this distinction the subject of the classification of the facts remains elusive and unsatisfactory from every point of view. When the division of the cases into the two groups is systematically made a large group of cases commonly regarded as atypical at once fall into their proper nosological category as

* Read before the Philadelphia County Medical Society.

forms of bronchopneumonia. These include among others, for example, since these remarks are intended to be suggestive and in no sense to constitute a systematic discussion of the subject, acute pneumonic phthisis, syphilitic pneumonia, many of the reported cases being apparently tuberculous, inhalation or deglutition pneumonias, postoperative and anæsthesia pneumonias, hypostatic pneumonias, and influenzal pneumonias. The pneumonias of other acute infections, especially measles and pertussis, also must be referred to this great group.

Speaking from the ætiological standpoint the initial pneumonia of rare cases of enteric fever—pneumotyphus of the French—though it is not a bronchopneumonia in the ordinary sense, cannot be regarded as an atypical form of croupous pneumonia. On the other hand, the pneumonia which occurs in malaria would appear to be in most instances an intercurrent croupous pneumonia.

When the above cases are referred to their proper nosological position there remains to be considered the second great group of cases of croupous pneumonia, probably the most important of the acute infectious diseases of the present historical epoch. just as enteric fever was the most important of the last century, typhus of the previous three centuries, and the plague the most important of the middle ages. The plague, typhus, and enteric fever have lost their terrors for our civilization because our methods of living are hostile to their spread and we have learned, even if we do not universally observe them, the sanitary laws by which they can be controlled.

Croupous pneumonia yet defies us. We are as ignorant of the causes of its endemic prevalence as our fathers were of the causes of the epidemics of the great pests of their historical times. The problems in regard to it which we are resolutely setting ourselves to solve—for it is a matter of life or death—contain unknown quantities which at present baffle solution. But the great problems of the past have been successfully and brilliantly solved and preventive medicine is capable of this great ordeal of the present.

The typical form of croupous pneumonia, the classical form, is alike at the bedside, upon the post mortem table, and in the laboratory as it comes into evidence from both life and death, the very type of an infection in which the clinical phenomena and the pathological findings are correlated. In the whole domain of clinical pathology it would be difficult to find a better example of conformity to type. Yet here, as in all biological research, we no sooner recognize the type than our attention is drawn to the variants. Clinically, there is every degree of departure from

type to extremes beyond our art to recognize. Pathologically the lesion, however circumscribed, however remote from the ken of the clinician, is definite and characteristic. Symptoms and signs may be at fault, but the fibrinous exudate and the pneumococci are there.

It is difficult, therefore, to draw a sharp line between the classical and the atypical cases. Here, as in other uncertain matters in our art, we are compelled to content ourselves with conventions. It is generally agreed among descriptive writers upon croupous pneumonia that the cases occurring in infancy and old age and in drunkards are atypical. Yet most of us have many times seen perfectly typical cases under these conditions. Nevertheless the following forms are generally regarded as differing sufficiently widely from the type to deserve separate and special consideration:

1. *Pneumonia in Infants*.—The local lesion in this form is much more common in the upper lobes than in adults. Like other infectious diseases, at this period of life it often sets in with convulsions. Cerebral symptoms, especially torpor, retraction of the muscles of the back of the neck, occasional excitement with muscular twitching, may suggest meningitis. Cough may be slight or, as in cases that I have seen, absent altogether.

2. *Pneumonia in the Aged*.—The disease may develop insidiously and without a chill. Cough and expectoration are slight and the physical signs obscure. There is great tendency to pulmonary œdema. The gravity of the constitutional symptoms is altogether out of proportion to the local lesions as indicated by the physical signs. The prognosis is grave.

3. *Pneumonia in the Alcoholic*.—*Pneumonia Potatorum*.—This form is often overlooked, since the symptoms are masked by those of delirium tremens, especially when the attack occurs during a debauch. The onset is insidious and the fever slight or absent altogether. The stitch in the side, cough and expectoration, even dyspnoea may be absent altogether and the actual condition recognized only upon routine examination.

A second variety of this form of croupous pneumonia is seen in individuals who are habitual consumers of alcohol in large amounts, but who do not present the signs of intoxication. Here the pneumonia begins in the usual manner, abruptly with a chill, pain in the chest, dyspnoea, and elevation of temperature. Cardiac failure, septic phenomena, and prune juice expectoration speedily develop, and profound asthenia is a characteristic condition. The prognosis in such cases is highly unfavorable.

4. *Toxic, So Called Typhoid Pneumonia*.—This condition is a pneumococcus septicæmia with secondary infection. The constitutional phenomena are severe; the evidences of pulmonary exudate are slight or absent altogether. Profound asthenia, ataxic symptoms, and wandering delirium are often associated with the jaundice and gastrointestinal symptoms. A positive diagnosis cannot in all cases be made during life. The pneumococcus has been isolated from the blood.

5. *Epidemic Pneumonia*.—Multiple cases of croupous pneumonia occurring in prisons, garrisons, and sometimes in private houses show typical and atypical forms. The cerebral, circulatory, and abdominal symptoms of so called typhoid pneumonia are frequently present and the death rate is high.

6. *Larval Pneumonia*.—Undeveloped forms of pneumonia are occasionally encountered. There are two groups of cases, the more common being those in which the onset is characteristic, with chill, moderately high temperature, the evidences of local exudate speedily following with cough and rusty sputum, the whole process terminating by crisis within two or three days. This form is described as abortive. In other cases the sickness is slight, chilliness being followed by moderate fever with unsatisfactory physical signs and no characteristic expectoration. The diagnosis at best is a probable one, though it becomes more definite when such cases occur during local epidemics and show herpes.

From the standpoint of the pulmonary lesion the following atypical forms are to be considered:

1. *Upper Lobe Pneumonia, So Called Apex Pneumonia*.—This form is common in infants and young children. It occurs also later in life and is sometimes attended with marked cerebral symptoms, while chest pain, cough, and expectoration are not marked. In the absence of a systematic routine physical examination this form of pneumonia may be overlooked.

2. *Pneumonia Migrans*.—Cases of this type are rare. The disease begins with characteristic phenomena, one lobe after another being in turn the seat of the exudate, the regions first involved successively clearing up. The whole course of the disease is prolonged and termination is commonly by lysis.

3. *Central Pneumonia*.—The onset may be characteristic and the constitutional phenomena severe. The pulmonary lesion is, however, remote from the periphery of the lung and does not yield definite physical signs. In the course of several days' dulness, crepitus, and bronchial respiration may be detected, at first over a limited area.

The course of the disease is usually characteristic and the termination frequently by crisis.

4. *Terminal Pneumonia*.—Croupous pneumonia constitutes the terminal event in many chronic diseases, especially phthisis, valvular disease of the heart, chronic nephritis, diabetes, and disease of the spinal cord. The condition is very often latent, in the first place because it often gives neither constitutional nor local phenomena indicating its presence, and in the second place because the patients are very often too ill to be systematically examined. The condition reveals itself only upon the post mortem table, where circumscribed regions of the lungs or the greater part of a lobe are found to be the seat of the characteristic fibrinous exudate, very often in the stage of gray hepatization.

5. *Pneumonia in Pulmonary Emphysema*.—The constitutional symptoms are commonly well marked and characteristic, the onset being sudden with chill, followed by high fever and cough. Rusty sputum is scanty or absent. Herpes appears, but the emphysematous condition of the lungs fails to reveal the presence of consolidation, and pain in the chest is commonly absent. The greater capacity of the vesicular structure and the diminished richness of the intervesicular capillaries account for the absence of physical signs. The supply of blood from which the coagulable exudate is poured out is less than normal, and the vesicular spaces into which it is poured more capacious.

A lady, 76 years of age, who had long suffered from bronchitis and had become highly emphysematous, had a severe chill with temperature rising above 104°, with cough, herpes, delirium, stupor. Death occurred with the signs of pulmonary œdema upon the fourth day.

6. *Hæmorrhagic Pneumonia*.—The chill is followed in the course of a few hours by the more or less abundant expectoration of blood and this may continue for several days, gradually diminishing. The course of the disease and the physical signs do not differ in other respects from the ordinary form.

A gentleman, more than 90 years of age, was suddenly seized with chilliness and epigastric pain radiating to the right. In the course of a few hours he had abundant hæmoptysis, which recurred at intervals of ten or twelve hours. He became stuporous, with occasional slight cough and tenacious rust colored sputum, which later, as jaundice developed, became of a greenish yellow color. The lower lobe of the right lung became consolidated, with crepitus followed by bronchial respiration. Death occurred with the signs of pulmonary œdema upon the fifth day.

The diagnosis of typical cases of croupous pneu-

monia is unattended with difficulty. Errors arise much more frequently from carelessness than from ignorance. Too much importance cannot be attached to a systematic routine examination of the chest in all cases of acute disease beginning abruptly with chill followed by fever or presenting pulmonary symptoms. The diagnosis becomes difficult in proportion as the departure from type becomes more marked. In the extreme forms of atypical pneumonia—the terminal pneumonias—the clinical diagnosis is very often impracticable. Herpes, which occurs in more than half the cases, is of diagnostic importance. The detection of the pneumococcus in the laboratory reinforces the clinical diagnosis. It can only rarely be utilized in diagnosis except to this extent.

Leucocytosis is an almost constant phenomenon. Its diagnostic importance is diminished by the fact that it also occurs in most of the conditions in which the question of diagnosis arises. Leucopenia is of most unfavorable prognostic significance.

1509 WALNUT STREET.

NASAL OBSTRUCTION AS A CAUSE OF DISORDERS OF NUTRITION.

By PERCY FRIDENBERG, M. D.,

NEW YORK,

ASSISTANT SURGEON, NEW YORK EYE AND EAR INFIRMARY, ETC.

While the rôle of digestive disturbances as an ætiological factor in the causation of nasal, pharyngeal, and laryngeal disease has attracted attention commensurate with its therapeutic importance, the reciprocal relation of gastrointestinal disease and malnutrition as a result of many affections of the upper respiratory tract, particularly those associated with mouth breathing, and its hygienic significance, seem to have received insufficient notice. In a "symposium" on this subject at the New York Academy of Medicine, a year or two ago, a number of papers were read, and a discussion followed in which many prominent laryngologists participated. The influence of gastric and intestinal disturbances, of hyperacidity, dyspepsia, hepatic torpor, constipation, and plethora, as factors in the production of nasal and nasopharyngeal disease was dwelt upon at length, yet strange to say not one word was said about the influence upon the intestinal tract, nor upon the various digestive functions, of diseases of the nose, rhinopharynx, and tonsils. This but reflects the attitude of the textbooks, which, almost without exception, pass over this subject or give it cursory mention, while dilating in a perfunctory way on the traditional observations of congestion of the lingual tonsil and oropharynx in drinkers and

plethoric individuals, the action of purgatives in acute affections of the upper respiratory tract, irritable cough due to indigestion, colds induced by hyperacidity, and so forth.

This omission is the more surprising when we consider the connection between the nasal respiration—the moistening, heating, and filtration of the inspired air—and the sense of smell, with the various functions of taste, appetite, and mastication, and with the disturbances of these functions in their various manifestations, from anorexia to constipation or diarrhœa.

When we remember how important a part taste and appetite take in digestion, and the rôle played in degustation by the nasal mucosa, we shall not be amiss in alleging that the nose stands at the beginning of the gastrointestinal tract as an accessory, if not as an integral part physiologically of the digestive system. While it may be impossible to separate the nasal factor of anosmia and deficient aeration from the systemic agencies in analyzing such a symptom as the anorexia accompanying a cold, there is no doubt of its presence. Alteration of taste, insipidity, unpalatableness of food, and with it loss of appetite, are common symptoms of a fresh coryza; the cause of similar symptoms in a milder form is apt to be overlooked when due to chronic nasal disease, and when they have become inveterate. The sense of smell is important not only for digestion and appetite, but as a guard against deleterious elements and putrefactive changes in the nourishment. The anosmia may lead to a marked blunting of taste, causing lack of discrimination in diet, eating spoiled or badly cooked food, and the abuse of spices and condiments.¹ Anorexia may be due to deficient aeration alone, and its effect upon the system caused by faulty respiration in mouth breathing. The stimulating effect of fresh air on appetite, and the opposite action of the stuffy atmosphere of crowded or ill ventilated rooms, suggests itself at once.

For the process of buccal digestion, with its elements of mastication, insalivation, bolus formation, and deglutition, the importance of normal nasal functions, and the marked influence of any disturbance in them, appears still greater—greatest, perhaps, in the infant, where suction is the main function in gaining nutrition. The subject of infant feeding is generally considered exclusively from the standpoint of the chemical constitution and nutritional value of the mother's milk and its various substitutes; although there can be no doubt that a large percentage of digestive disturbances in nurslings is caused by a faulty method of taking nourish-

¹ A similar blunting of taste is observed in many chronic affections of the oropharynx, accompanied by abnormal predilection for sharp and highly seasoned food.

ment, and not to the composition of the nourishment itself.

The child at the breast requires for the ingestion of a single meal about one quarter or one half hour. It does not take its mouth from the breast during that time, *provided that it breathes through the nose*, and hence swallows no air. A strong negative pressure of from 50 to 140 c. cm. of water is produced (Cramer) which stimulates production of gastric juice (Pfaundler) and causes a certain amount of fatigue; so that the child falls asleep without crying or vomiting.²

Nasal obstruction or any allied condition leading to mouth breathing is deleterious in two ways; it interferes with respiration, and interrupts the process of feeding and swallowing. The little one, forced to breathe through the mouth or suffocate, sucks spasmodically, with frequent stops for breath, gasps, strangles, gulps air, and, later, vomits. These symptoms are almost pathognomonic for the nasal obstruction due to adenoid growths. Either an insufficient amount of nourishment is taken, or large quantities of milk mixed with air are swallowed, instead of the milk entering the stomach a little at a time. The results for digestion and nutrition are evident.

In young children similar causes lead to somewhat similar effects, modified by the fact that solid food is ingested, and thorough mastication is wanting. Here, too, we have bolting of food and gobbling, so often attributed to greediness or haste, and that may, of course, be due entirely to such extrinsic factors, if I may so term them, but they are not seldom the expression of an inner necessity—that of getting in air and food through the same portal. Granted nasal obstruction, breathing can only take place as mouth breathing “between drinks,” or between gulps, and neither function is performed normally. The effect of the action of the muscles of mastication on the development of the jaw, alveolar arch, and teeth is too well known to need more than brief mention. Habitual lack of this action in mastication, plus the mechanical effect of the open mouth and the hanging jaw, help to produce the narrow adenoid arch, the protruding, overlapping “buck teeth,” and, as a natural result, difficult, delayed, or irregular dentition. That such a jaw does not close and given an even bite, and that such teeth again are incapable of doing their work of mastication thoroughly, are difficult to keep clean, and apt to decay, is apparent; and so the result becomes a cause of indigestion and malnutrition as the vicious circle is completed. In this connection Spratling's observations³ are of great in-

terest. This author concludes that difficult dentition may in suitable subjects constitute a sufficient irritation to cause convulsions, and that these may ultimately lead to epilepsy. By “suitable subjects” Spratling means individuals who inherit a neuropathic tendency to disease; and he is of the opinion that gastrointestinal disorders may produce similar results. That the air taken in through the mouth is not inspired in the true sense is evident—it is neither warmed, nor moistened, nor filtered as it is after nasal inspiration, and so is not prepared for pulmonary use. The effect on intimate respiration and on the general health is an important and interesting topic, but one which is somewhat aside from those here considered. The lack of exercise of the thoracic respiratory muscles in mouth breathers has its important mechanical, structural, and functional results in underdevelopment of the thorax, flat or pigeon breast, phthisical habitus, and, as I really believe, phthisical predisposition on the one hand; and lack of energy, sleepiness, phlegma, apnoea on the other.⁴

The study of the saliva is still in its infancy, but the observations of Kyle, Hays, and others show that its abnormal composition may cause malnutrition, and, again, that such chemical changes may be due to nasal and nasopharyngeal disease. Add to this that an open mouth, perforce open for air, is, or soon becomes, a dry mouth, so that saliva and other peptic or lubricant secretions are insufficient, as well as abnormal, scanty, and bad.

Deglutition is affected by two factors. The first, an indirect result of mouth breathing, is the character of the bolus, which is not sufficiently comminuted and softened by mastication, or moistened, “ptyalized,” and lubricated by insalivation. The other, due to the necessity for getting air, is the bolting of food, with disturbances in cesophageal action, “swallowing the wrong way,” hiccough, regurgitation, and the like. An artificial aid to deglutition is then found in drinking water as a substitute for chewing and insalivation, not only to soften the bolus, but actually as a mechanical aid in deglutition. The food is washed down with copious draughts, distending the stomach with a thin extract of food.

⁴In a recent issue of the *Journal of the American Medical Association* a writer gravely states that the main danger of mouth breathing lies in the insufficiency of air, in air hunger, to satisfy which a great strain is brought upon the inspiratory muscles of the thorax, to which they eventually succumb. The modus operandi of mouth breathing is, however, just the opposite. The air taken in at a breath from the mouth is quite sufficient, and much larger than that usually inspired through the nose, as one would expect from the size of the channel, and as is shown further by the fact that when out of breath from exertion or any other cause we gasp for air through the mouth, “like a fish out of water.” The danger of mouth breathing, aside from the bad quality of the air referred to above, lies in the fact that it takes place with little or no respiratory effort, and that sufficient air is taken in to satisfy the lungs without a good, deep breath. The result is that breathing becomes habitually superficial and the chest remains undeveloped.

² A. Schmidt. *Münch. medicin. Wochenschr.*, November 29, 1904.

³ *Medical News*, October 10, 1904.

Nutrient thus insufficiently prepared, largely diluted with water, and mixed with air in the buccal cavity is digested with difficulty and is likely to cause gastric and intestinal disturbance. This morbid process may be further encouraged by the entrance of the products of purulent inflammation or mucous hypersecretion into the stomach from the nose or pharynx by gravitation, or from the larynx and trachea, or even from the bronchi and lungs, by swallowing after expectoration. That this secretion is allowed to accumulate and to make its way into the stomach is an observation frequently made in children, where it is almost the rule; and it is by no means unusual in the case of adults. The same thing holds true of laryngeal and pharyngeal secretion which, though expectorated, is not infrequently swallowed, instead of being rejected *per os*.⁵

Expectoration is not synonymous with spitting, although often used in this sense. The latter is very properly forbidden in cars and other public places; but one of the minor evils of this reform is the inhibition of all expectoration, however necessary. The result, I am convinced, is but too often that expectorated masses are actually swallowed. How often, in our catarrhal population, do we hear and see people "clear the throat," and how seldom is the expectorate or sputum rejected into a handkerchief or other proper receptacle? What has become of this matter is only too evident. It has been brought up from the air passages and consigned to the all tolerant stomach. In children, nasal secretions are often disposed of in the same way. The habit is all but universal; and so common that some sensitive souls express disgust at the sight of any one coughing or spitting into a handkerchief.

These conditions being due to nasopharyngeal disease and not to mouth breathing *per se*, it will suffice to have called attention to them, and to their well known complications. Among these we may mention the sudden increase of intraabdominal pressure and the injurious effect on the viscera, particularly on the lower bowel, or on a possible hernia, of excessive coughing, violent sneezing, hawking or "clearing the throat," and blowing the obstructed nose, and the causation of obstinate hiccough, retching, and even vomiting, by these acts.⁶

The morbid processes will persist for a time even if the causes, mouth breathing, insufficient mastication, and the like, have been removed. When the

⁵ The deleterious effect on digestion of swallowing morbid tonsillar secretions was noted by Yearsley a half century ago, and Turck has recently drawn attention again to the dependence of gastric disturbances on direct infection from germ laden nasopharyngeal secretion.

⁶ Gagging and vomiting may also be caused by irritation of the fauces from enlarged tonsils, or a pendulous uvula. Septic or irritant matter may thus be thrown into the posterior nares and infect the middle ear by way of the Eustachian tube.

latter have been present for some time the vicious circle has become habitual. Makuen says (*Bulletin of the American Academy of Medicine*, August, 1903): "There are many obstructions to normal breathing; and when once the natural rhythm of the breathing process is perverted it can never be entirely restored without conscious effort and well directed practice." It is not sufficient to correct nasal deformity, to remove adenoid and tonsillar hypertrophies, to do away with mechanical obstacles. These procedures, however radical, give the possibility alone of nose breathing; they by no means insure it. Until this is accomplished, until habits of mastication and respiration are trained and taught to be performed normally and thoroughly, each in its own province, mouth breathing will continue in spite of a permeable respiratory tract. This is particularly noticeable, as I have pointed out in a previous communication,⁷ in children who have been operated on for adenoid growths. As they have never learned to breathe through the nose they will continue to be mouth breathers until they have unlearned this habit and acquired the new one. Prolonged and thorough mastication is an invaluable aid in this training, and in my opinion at least as important as respiratory and thoracic gymnastics. I have advised that children be allowed, or rather encouraged, to chew gum until the nasal respiratory modus has become established. Cold sponging of chest and back, physical exercise, singing or reciting, and occasionally the use of a respirator or chin bandage at night are further aids to nasal respiration. The latter is more apt to be overlooked when the children are at school, or bent over their books, and it is advisable that the sessions should be interrupted, half hourly at least, for a few respiratory gymnastics. This need take but one or two minutes, during which the children are to stand and stretch out to their full stature, clasping their hands behind their heads, breathing deeply, and fully expanding their lungs and extending the vertebral column. A few simple exercises, such as the swimming motion with the arms or a short march around the schoolroom, may also be instituted. Special attention should be paid to the posture of children while at their books, so that anything may be avoided which encourages a crouching body, collapsed lungs, bent back, folded arms, or lowered head. Among such factors are badly printed books, small type, insufficient illumination, the habit of reading on into the dusk without light, and simple sluggishness.

MALNUTRITION IN YOUNG CHILDREN.*

By THERON WENDELL KILMER, M. D.,

NEW YORK,

ADJUNCT ATTENDING PEDIATRIST TO THE SYDENHAM
HOSPITAL, ETC.

The human being is the only mammal that does not know how to take care of its young. Is it to be wondered at, then, that the physician is constantly called upon to treat cases of malnutrition in children? What are the causes that operate to bring about this distressing condition?

(1) Lack of parental knowledge of the correct method of rearing children;

(2) Diseases of the child;

(3) Diseases of the parents.

LACK OF PARENTAL KNOWLEDGE OF THE CORRECT
METHOD OF REARING CHILDREN.

The first and foremost factor in the causation of the production of such an alarming number of undersized, thin, pale, weak eyed and flabby muscled children is the fact that those children's parents know very little about their offspring. These self same parents were the children probably of healthy, hard-working parents who ate their three good square meals a day, had a happy home, and loved to be in close relationship with their children. Parents of this class knew every little whim and fancy of their offspring; they fed their babies on Nature's own food, breast milk; they had plenty of it and to spare. When their children became old enough to eat other articles of diet, it was the parent who prepared that food. When their child was ill, who was it that took care of that little patient? And who can watch and care better for a sick child than its mother? That, then, was the influence that in the early days surrounded the parents of the child of the twentieth century. In consequence thereof we grew up in the path that Nature had mapped out for us. We went to school at a reasonable age, romped out of doors every minute when not in the schoolhouse, ate our meals at certain definite times, went to bed early at night, and never knew that there was such a thing as alcohol. Such a life has been the experience of nearly ninety per cent. of the parents of the children of to-day. But, alas! How changed are the mode of life, habits, and surroundings of the present generation of children! Born of healthy parents in a steam heated flat, these children are first fed on breast milk, and in this regard the parents show the good result of their own early training. The baby vomits—all babies do—and immediately a host

of nursemaids, kind (?) friends, and neighbors advise withdrawing that baby from the breast, as somebody else in their acquaintance nursed her baby with "bad milk," and the baby had convulsions! Imagine what an influence such advice is apt to have upon the secretion of breast milk in a mother who is already worried by the servant question. The mother, never thinking it necessary to consult her physician, foolishly takes the advice of her ill advising friends and, heart sick and discouraged, begins to try to bring up her baby as she hears a twentieth century baby should be reared. Cows' milk is now tried, and usually it is not diluted sufficiently. The baby becomes colicky, constipated, vomits, and does not thrive. Condensed milk is now given a two weeks' trial; it is usually given as weak as the solution of cows' milk was strong, and it, too, is thrown to the wall. To enumerate the patent foods that now come upon the scene would take your time and patience, and would elicit remarks from the writer that are not proper to be preserved in the archives of this society. One food after another is tried, and all to no purpose. If the parents condescend to accept the advice of a physician at this stage, all yet may be well, but if they do not wish to interfere with the plans of their friends, then that baby is certainly destined to tread the path of the poorly nourished. If such a child does survive the first two years of its life, he is thought to have escaped the "dangerous period," and then may be fed on anything. He usually is fed on anything and everything. He is generally fed irregularly, on half cooked cereals, ten minute breakfast foods, and raw vegetables; and, not relishing these articles of diet, he makes most of his meals of bread, potatoes, and "cambric" tea. We have all seen these children; they are constipated, pale, thin, and flabby, with an appetite that is capricious; they are poor sleepers; many of them wear glasses; and their parents consult us because they wish their boy or girl, who has now arrived at the age of four to ten years, to be made strong! Well may these parents wish it, and high time is it that they consult their physician as to the welfare of their offspring. The prevailing innate idea that, as soon as a baby has recovered from the shock of entering childhood, he should be plunged into a kindergarten, is the cause of many a case of foul air headache and paling cheek. If he ever in his life needs fresh air, he needs it now. "Training up a child in the way he should go" is proper and highly to be desired, but as for the twentieth century so called higher education, where young children are expected to recite lines of Homer's Iliad and to converse fluently in four languages before they are ten years old, I claim that such a higher education is bound to produce an

* Read, by invitation, before the Medical and Chirurgical Faculty of Maryland, at Baltimore, Md.

inferior race of human beings. If a breeder of animals wishes to produce the very best of a species, he feeds the young animals on certain articles of diet that will bring about the end he desires. These animals are fed regularly, groomed, and cared for in the best possible manner. Does not an offspring of the human race demand as great care as that bestowed upon beasts? He certainly does, but yet he does not get it. Large, roomy, well ventilated box stalls are fitted up for horses; yet the baby of the household is reared in a dark, gas lit, inside bedroom opening on an air shaft! The everyday picture of a thin, pale, ambitious half grown boy or girl, carrying to and from school a pile of books that would do credit to a free library is a sight with which we are all familiar. Did we as youngsters have as large a number of books from which to learn our lessons? No, we did not, and yet we consider ourselves quite equal to cope with the hard, common sense problems of either a lay or professional life, notwithstanding that we did not quote Virgil when twelve years old. We never in our young childhood were compelled to go to our room immediately upon returning from school and remain there till evening, eat a light supper, again to return to our problems in geometry and algebra, until finally tired, eyesore, and faint, we turned to our beds to find what sleep an exhausted, overworked brain and ill exercised body would give to us! We, on the contrary, remember returning from school, throwing our few books into the house, and going immediately out again to enjoy a game of baseball or to go skating. When we returned at five or six o'clock we had an appetite for the good and wholesome meal that was set before us. It was either eat it or leave it. There was no coaxing or buying necessary to make us eat. Our appetites were the only whips. After our outdoor exercise and our satisfied digestion we went early to bed and were asleep about as soon as our heads touched the pillows. Chorea, brought about by overpressure in school, was an almost unheard of disease; and yet now how common an ailment it is and how numerous are the cases of St. Vitus's dance that we see almost daily in both private and outpatient work! On the other hand, the pace at which we are required to live is most rapid. We are compelled to work twice as hard, sleep half as much, and spend twice as much nowadays to obtain the same ends as we used years ago. Our mode of living is changing. Too much cooking is done in the factory and too little in the home. The servant question is possibly responsible for this state of affairs, and in consequence thereof the middle class, rather than pay impossible wages to servants, prefer to live on breakfast foods and the products of the delicatessen store and the bakery.

The myth called "higher education" has become entangled in the heads of the lower classes, so that a servant who formerly was willing and glad to work at every kind of housework at moderate and just wages is not now content unless she can find a position in the factory so that she can have her evenings off to attend "night school." This would be a commendable state if it was true. The extreme upper classes pay comparatively fabulous sums to servants in order to entice them to remain, and in some cases even theatre tickets are furnished as a reward to the faithful, and in consequence of this lavishness the middle class suffers for want of servants, and children are therefore sadly neglected. The servant question has at last entered the realms of medicine, and become an aetiological factor in the production of disease. The extreme desire to be upon the top round of the social ladder is also responsible in part for the necessity of the rapid and strenuous life of the average twentieth century woman. "My social engagements first, then my children," says many a social leader. I know of families the mothers of which do not see their children for days at a time. They have a telephone or speaking tube to the nursery and deem this sufficient parental intercourse with the children of their hearts. The punch bowl, the cocktail, and the cigarette were unknown articles in the lives of our mothers, yet what a prominent feature are they in the daily lives of many of the mothers of to-day! Can a woman successfully produce a perfect breast milk who is continually stimulated by the use of black coffee and alcohol? The increasing number of unhappy marriages, divorces, and strained social relations are not the atmosphere most conducive to success in rearing well nourished, sweet tempered, and normally developed children.

So much, then, for the consideration of the first division which I have made of my subject—namely, the lack of parental knowledge of the correct method of rearing children.

DISEASES OF THE CHILD.

A child may be brought up under the best surroundings, with ideal diet and care, and still fall under malnutrition. I speak of children that are ill or have had some disease which has impaired their bodily functions and in consequence of which they have become emaciated and are not thriving. Of course our first duty in these cases is to treat the disease and then to build up the child according to the rules laid down under General Treatment of Malnutrition. Adenoids and enlarged tonsils are great factors in causing malnutrition in young children, and upon removal of these growths the child becomes a different individual entirely in a few weeks.

We now pass on to the third and last division:

DISEASES OF THE PARENTS.

In cases of malnutrition, where you have exhausted every known method of proper feeding and prescribed fresh air, proper bathing, and hygienic surroundings, and notwithstanding a month's or six weeks' trial, the child does not respond, always suspect syphilis. Many cases of malnutrition in children are treated for years with no beneficial effect whatsoever until they come under the care of some physician who realizes the probability of syphilis, immediately institutes a form of antisyphilitic medication and the child is a different child altogether in a month's time. These cases of syphilitic malnutrition are usually hereditary cases, where the father in his younger days had a chancre, and the physician who treated the father told him he was to all intents and purposes cured. He marries and begets a child who suffers from malnutrition. There are none of the "textbook" symptoms of syphilis present, such as rash, enlargement of the liver and spleen, or bony changes; there is simply malnutrition. This is in many cases the only symptom, as is admirably set forth in an article entitled *Malnutrition as Shown in Congenital Syphilis*, by Dr. C. G. Kerley, of New York. There may be enlargement of the epitrochlear glands; there may be Hutchinson's teeth of the pivot, notched, or screw-driver variety; there may be bird claw fingernails or toenails; a history of snuffles in early infancy; a rash a few weeks or months after birth. There may be present an enlarged liver or spleen. So that given a case of malnutrition in a young child who does not improve after careful feeding and hygienic regulation—no matter whether the father or mother are pictures of health and morality—treat that case for syphilis and you will be surprised at the result obtained. I usually employ the bichloride of mercury, beginning in doses of one one hundredth of a grain morning and night to a child of three to four years old, and gradually increasing the dose up to the amount which brings about improvement. Children bear the mercurial well, as it is impossible to salivate a baby. Frequent green stools are an indication that the maximum dose has been reached. Mercurial symptoms in young children are very infrequent. Potassium iodide may be combined with mercury to advantage, commencing by giving two to three drops of a saturated solution three times a day and increasing up to a diminution of symptoms or an iodide rash. The iodide is usually well borne by young children. I do not use ointment, on account of the irregularity with which it is usually applied by parents. It soils the clothing and is objectionable. Of course, aside from the anti-

syphilitic treatment a régime of proper diet and hygiene should be continued.

THE GENERAL TREATMENT OF MALNUTRITION.

The Sleeping Room.—The room in which a child with malnutrition should sleep should be the best room in the house. The idea of keeping the best room in the house as a spare room or guest chamber, which is almost never aired nor entered except there come strangers to the house to visit, while the family sleep in some ill ventilated portion of the house, is a wrong one and should not be entertained. Many are the families in moderate circumstances which have the only decent living room in their apartment used as a parlor, while the members of the family repose in inside rooms opening on airshafts or so called courts. The child suffering from malnutrition should sleep in the best room obtainable—the parlor, if necessary—as his future welfare is far more important than the satisfaction of the whims of the family. There should be as much sunshine and fresh air in the room as it is possible for Nature to place there. The windows should be fitted with window boards which allow of fresh air, but no draught. The temperature of this room should be kept at 68° F. during the day and may be allowed to go down as low as 50° F. during the night. Fresh, cool air never hurt anybody, gave a cold, or killed a person; but an ill ventilated, steam heated room, reeking with the breaths and rebreathed air of whole families, coupled with the odors emanating from neighboring kitchens, is responsible for many a case of chronic cold, and death.

The Bedclothing.—The bedclothing should consist of a suitable mattress of either hair or felt, covered by a pad. The child should sleep between well dried sheets, having for covering as many blankets as is consistent with the degree of temperature in the room. A hot water bag or bottle should be placed, well guarded, at the feet. The child should wear cotton night drawers or a cotton night shirt.

The Clothing.—The underclothing should be preferably of mixed cotton and wool. A great mistake is made by prescribing too heavy underclothing. A medium weight is to be preferred. The outer garments should be such that their weight may be changed according to the weather and temperature. A child should not be bundled up too much. He should wear thick gloves or, better, mittens in winter and should never acquire the "muffler habit," which is responsible for many a laryngitis and chronic bronchitis. Thick soled, broad toed shoes should be worn. The feet should never be allowed to become damp.

Exercise.—The child should be out of doors as much as possible on pleasant days. On stormy days he should be clad in his outdoor garb, the windows

raised and given his airing indoors. The child should be allowed to run, romp and play games as much as he pleases, when out of doors.

Bathing.—A child should have a bath once a day, preferably in the morning. This bath should be given warm, 90° F., and the child should remain in it for ten minutes. Half a pound of sea salt should be dissolved in each bathtub, half full of water. The child should be rubbed with the bare hand while in the tub. Any soap but castile soap (and that very sparingly) should be excluded. When the child is taken from the bath the skin should be rubbed briskly with a coarse Turkish towel until the surface is thoroughly dry. The body should then be anointed with from a half ounce to one and a half ounces of olive oil. The skin will vary in different individuals regarding its power of absorption; some children's skins will absorb but half an ounce of oil, while others will absorb an ounce and a half. This oil should be rubbed well into the skin.

School.—A child should not attend school until he is seven years old. Kindergarten for the young is useful and instructive in that it keeps young children amused and trains their minds by the use of simple games, exercises and songs. In a well constructed home, where a mother, father, relative or competent nurse can devote a few minutes each day to the simple training of the young mind by reciting alphabets, singing songs, reading or telling proper stories (not *ghost* stories), using building blocks, moulding lumps of soft clay, teaching elementary sewing and drawing, a child reared in such a family need never go to kindergarten. Where such instruction is impossible to attain at home, then an hour at kindergarten daily is advisable. Not till the child is five years old, and then only upon the advice of the family physician, who should examine it for any symptoms of malnutrition or chorea, should it be allowed to attend school. Should the physician find such symptoms, he should advise against sending that child to any school whatever until such symptoms have disappeared. But how rare is it that the family physician is ever consulted regarding the advisability of sending a child to school for the first time. This should not be so. Children should not be compelled to learn the hard advanced lessons that are seemingly required today of nearly all young children of school age. I am glad to say that there has been inaugurated a movement to appoint special teachers for the instruction of backward children in our public schools. A child should be mentally fed with as great care and deliberation as would be used in feeding that child by mouth. Volumes are written in medical journals regarding the feeding of children, yet how few articles do we find in these self same journals

that deal with the mental feeding of the human race. Children should have ample time to eat their luncheon; they should not be compelled to travel a long distance home, eat a ten minute luncheon and run all the way back to school again for fear of being late. The noon hour recess has been lengthened in most of our public schools, and that very advisedly. Ventilation of the school room and overcrowding are pertinent problems with which the educators of our land have been contending for and gradually remedying. A child presenting symptoms of malnutrition should be taken out of school. His health is of more importance than his learning, and, by giving him health, you likewise give him the means of attaining better cerebral absorption.

Sleep.—Children should have a daily nap until they are five years of age. A child with malnutrition should be put to bed early, say at 6 p.m., and should rise at 7.30 a.m. He should sleep alone in his own crib or bed. A bright light should not be kept burning in the room where a child is sleeping, as even a small light vitiates the air. Parents and attendants are more or less responsible for children being afraid to go to sleep in the dark by their having told the children stories such as would cause impressions of fright upon even an older brain.

Food.—Of utmost and prime importance is the selection of food to be given to children suffering from malnutrition, for without a proper régime of diet very little can be accomplished toward a cure. A child with malnutrition should be given a high proteid diet; it is the proteids that make flesh and blood and bone. He should be put upon a diet of milk, meat and eggs, oatmeal (which contains a high amount of proteid), soups such as purée of split peas, beans, and lentils. He should be given green vegetables. His carbohydrates should be cut down to a minimum and we therefore exclude to a small degree bread, potatoes, and sugar. Under no circumstances should tea, coffee, or beer be allowed. His meals should be given at regular intervals. Written instructions should be given to the parents regarding the articles of diet. In advanced cases of malnutrition it is well to feed a child every three or four hours, so that a child six years old would be given five meals a day. This does not mean that he is expected to sit down and eat five large meals a day, but that something to eat should be given him five times a day, and he is therefore fed small quantities, but at short intervals. It is my custom to give to parents of children suffering from malnutrition the following printed directions as to the details of the children's menus. You must give a parent something definite in the form of instructions as to the care and feeding of their children. It will not do to say: "Feed your child on milk, meat, and eggs,"

and stop there with your instructions. You must go further and tell the parent how and what to feed in detail.

DIET IN MALNUTRITION; CHILDREN 4 TO 12 YEARS OF AGE.

Breakfast, 7 to 8 a.m.—Oatmeal or wheaten grits (cooked three hours), and rich milk with a very small amount of granulated sugar. The cereals should be well salted; a soft boiled or poached egg; a small piece of stale bread or zwieback; a glass of good, rich milk.

10 a.m.—Glass of milk.

Dinner, 12 to 1 o'clock.—Soups of purée of split peas, beans (white or black), or lentils. Lamb, roast beef, steak, mutton, white meat of chicken, or fresh fish (boiled or broiled); stewed celery, asparagus tips, spinach, string beans, or peas, a very little mashed potato (two or three teaspoonfuls). For dessert an orange, baked apple, stewed prunes, rice pudding, plain custard. *The child must eat his dinner before any dessert is given to him.*

4 p.m.—Glass of milk.

Supper, 6 to 7 p.m.—A well cooked cereal and milk; stale bread in milk, milk toast, custard pudding, and a glass of milk.

Cool, boiled water should be given the child to drink between meals.

There are cases where you will be told that the parents have offered the child the articles of food that you have prescribed, but the child will not eat them. This is a frequent story. Oftentimes, when a child is of reasonable age, a good heart to heart talk with him by the physician himself, explaining why you wish him to eat the food you have ordered, that you want him to grow up big and strong, may have the desired effect upon him. Children usually require a reason explained to them for any new action. This is a fact that few think of, and therefore the simple command for a child to do a certain thing is followed by his asking "Why?" This is natural and should in no way be responded to by saying: "Because I tell you to." This reason is all right for the army, but not for the nursery. If a child, after having been talked to by the physician, still refuses to eat the articles of food set before him, there is only one means of procedure to adopt, and it always works. Do not threaten, whip, or coax such a child, as this will do no good, and only aggravate the already existing trouble. Put that child to bed and, if necessary, employ a trained nurse. Offer the prescribed articles of diet to him in his bed. He will ask why he is put to bed. Tell him that as he will not eat his food at the table he will be too weak to sit up and therefore must have his meals in bed, but as soon as he eats his food he will then be strong enough to sit up to the table, play games, and go out

of doors. This explanation usually suffices. If it does not, his food must be simply set before him at the stated meal hours and if, after having been left there for ten or twenty minutes, he will not touch it, ask no questions of him, but quietly remove the tray until the next meal time arrives and repeat the process. It will not be long before this child under this method of quiet, but firm management will be "broken," and he will eat his meals with a relish and vigor born of hunger. If a child in his anger and stubbornness shows a tendency to break dishes, tin plates can readily be substituted.

So much for pure dietetics.

Medication.—It is advisable in some cases of malnutrition coupled with poor appetite, to administer a teaspoonful of the following solution of iron and quinine citrate in sherry:

R Citrate of iron and quinine.....	1 grain;
Sherry	of each.....
Water	1/2 drachm.

M. Sig. For one dose; take three times a day after meals.

This seems to have in most cases a salutary effect upon the appetite. There are other cases in which codliver oil, if well borne by the stomach, may be given with advantage in doses varying from five to thirty drops three times a day after meals. In all cases of malnutrition we must keep on friendly terms with the stomach, for if ever a child needs a good stomach, he needs it in these cases. Any form of medication, therefore, that tends to upset the stomach should be discontinued. The child should be weighed regularly.

Cases of malnutrition that are treated along the indicated lines are certain to be improved. Vague coughs that are thought to be occasioned by adenoids, large tonsils, and malaria will be seen to vanish when the child is put upon the hygienic diet which I have mapped out. What, then, does it signify when over half of the children between the ages of four and twelve years seen at a children's clinic are under par, and what inference may we draw from the observation that we are constantly called upon in private practice to treat weak looking, pale faced, poorly nourished children? It signifies to my mind that (1) the care and feeding of children should be a part of the curriculum of our schools, where the rising generation, the coming parents, can be taught how to care for themselves, and in so doing they are better enabled to care for others; (2) physicians in general practice should realize the importance to the coming generation of a correct diagnosis in cases of simple malnutrition before commencing treatment of vague and atypical so called cases of malaria, chronic typhoid, and tuberculosis along the lines that these diseases would suggest; finally, by the observation of the foregoing two suggestions and by carrying out a scheme of treatment such as has been

outlined in the present paper, we have good reason to hope that the coming generation will be minus the stigma of the hordes of poorly nourished children whose presence is a blot, shame, and disgrace to the civilized world.

INFLAMMATION OF THE GLANDS OF BARTHOLIN.

By CHARLES C. MILLER, M. D.,

CHICAGO.

(Continued from page 738.)

THE EXCISION OF THE GLAND OF BARTHOLIN, WHERE CHRONIC INFECTION OF THE GLAND PERSISTS.

If a gland remains enlarged and palpable, it is very likely to be infected. An acute inflammation will result in the deposit of much inflammatory material in a gland. If resolution is slow more or less organization of the inflammatory material into connective tissue may occur, leaving the gland hypertrophied and palpable after the infection has disappeared, but this is not the rule and a palpable gland usually signifies an infected gland.

If a discharge persists from the duct, which discharge is more than a colorless mucus, the natural secretion of the gland, we can safely say that duct or gland is infected, and treatment as above outlined if futile should be followed by an extirpation of the gland.

The function of the gland is of secondary importance when we consider that the duct or gland alone may harbor a previous infection, and that the discharge from this gland may offer the only possible means of reinfection of the genital and urinary tract, and that in such a case sexual relations would be safe were it not for the constant menace of the discharges of the gland.

Pozzi credits Breton with being "the first to demonstrate that gonorrhœa might lie for a long time dormant in the excretory duct of the gland after the vagina was free from it, and starting from this point renew the infection. Zeissl confirmed this statement." Others have called attention to this possible source of infection, but the difficulty has been that the great majority of writers, particularly in this country, have conveyed the impression that this infection is first manifested by abscess of duct or gland. Dudley, in his book on gynecology, speaking briefly of these glands, has made a statement the probable true import of which has not been grasped by the majority of his readers. He said "the capacity of the glands to receive, retain, and distribute infection will often explain the frequently observed attacks of recurrent gonorrhœa in women."

The disease of the duct and gland which I have

just described and which has never manifested itself by any symptoms apparent to the woman since the acute infection, coincident with the acute vulvar or vaginal inflammation, is a menace to her, just as is the gland in which abscess has developed followed by fistula formation. The function of the glands need not deter us from extirpating them. Huguier correctly inferred that the secretions of these glands served to render the first approaches of the male less painful, and by maintaining the humidity of the genitals during intercourse furthered the retention of their extreme sensibility. These functions are of secondary importance to the health of the woman, and may easily be dispensed with if necessary.

The extirpation of the gland which is only slightly enlarged and which is not surrounded by inflamed tissues is comparatively simple, and can be accomplished under the influence of cocaine injections. Where the operator has had previous experience with cocaine and can deposit it with accuracy, from fifteen to thirty minims of the four per cent. solution of the drug will serve best in rendering the removal of the gland painless. If the operator possess but little skill in depositing cocaine, double the quantity of a two per cent. solution may be used to a better advantage, as with the larger quantity the less skillful operator is more likely to infiltrate all the tissues about the gland with the solution. The cocaine should first be injected along the site of the skin incision, then the needle should be carried down around the gland and beneath it.

The gland may be approached from the cleft between the labia majus and minus, and the subsequent scar will be concealed from sight, but this incision is not advisable in these cases and it is better to cut directly downward through the labium majus. The short incision, which serves to gain access to this type of gland, is inconspicuous and leaves an unimportant scar after being treated by immediate suture.

The bulb of the vagina is in close relation with the gland above and in front and, while injury to it is of no material importance, it is well to avoid it if possible. The skin incision should be directly over the gland, but should not extend too far forward. As soon as the gland is reached, it should be grasped with a strong toothed forceps and drawn strongly outward. It is now to be removed by dissection, keeping as close to it as possible, especially above and behind. A fairly large vessel runs beneath the gland and in spite of care it is sometimes wounded. As soon as the gland is free the cavity is to be packed with gauze. This is then removed and any bleeding

points are to be caught with forceps. Twisting is usually all that is required to control bleeding, though small catgut ligatures may be used if preferred. Closely applied sutures will control bleeding, and the operator may trust to this means alone if he wishes. The sutures should extend to the depth of the wound and where bleeding is persistent, they should be tied tightly. This is a simple operation, but it may mean much to the future health of the patient. Both glands may be removed at the same sitting and the patient need not be confined to bed.

I have not been in the habit of directing any attention to the duct, until the wound formed by the removal of the gland has entirely healed. A delicate probe is then to be wrapped with cotton, and the cotton is to be saturated with a ten per cent. chromic acid solution, and is then to be carried to the bottom of the duct if the duct is dilated or patulous. By manipulations the chromic acid is brought into contact with all parts of the duct and is then removed. The probe should then be rewrapped with sterile cotton and carried into the duct, and any excess of the chromic acid solution removed. The object of the chromic acid solution is to destroy the delicate epithelial lining of the duct so that its walls may adhere, and it is thus obliterated.

I have outlined briefly the symptoms and course of conditions which may be seen and studied by every gynecologist and many general practitioners. I hope they will appreciate the importance of these varieties of disease of the glands of Bartholin, and that from now on these organs will not be neglected until their pathological condition is manifested by the affections which I shall proceed to describe.

ACUTE INFLAMMATION OF THE DUCT AND GLAND OF BARTHOLIN WITH RETENTION OF PUS AND GLAND SECRETIONS.

This is the condition which is commonly described by writers as acute inflammation of the duct or gland. Acute inflammation without retention of pus and secretions differs widely from the acute inflammation which accompanies or follows an obstruction to the duct of the gland. A number of symptoms manifest themselves in this latter condition in an unmistakable way, and, in consequence of this, the disease has been recognized and described by gynecological writers for many years.

This variety of the disease where a retention cyst forms is one which causes much discomfort and inconvenience; it is fairly common, not infrequently recurs in the same individual, always with much discomfort and pain for two or

three weeks, and many times is followed by fistula formation. Reinfection of the genital or urinary tract may occur at any time, and the infected woman is a constant menace to any person with whom she may have sexual relations. In spite of all this, American writers have found but little to interest them in diseases of Bartholin's glands, and their descriptions of these diseases are brief and perfunctory. Mann years ago in the *American System of Gynecology* said "it is surprising how little has been written in American literature concerning the affections of these glands," and those words have remained true to the present day.

Acute inflammation alone has been accredited in the past as a frequent cause of occlusion of the duct. I have seen but two cases where I was convinced that infection had occurred within a month previous to the appearance of the disease. The gonococcus we must recognize as the most potent factor in producing an infection of the duct and gland. This organism produces most severe inflammations of the tissues about the genitals, and with such we would have the greatest degree of diminution in the calibre of the duct. At the same time we will have a profuse purulent discharge, and if this discharge becomes more or less thick or inspissated, we will have it acting as a factor in aiding in the plugging of the duct.

Trauma has been cited as a factor in the production of inflammation and enlargement of the gland. This trauma may occur during labor or intercourse. Such may predispose to excite an acute inflammation in an already infected gland, especially where there is an imperfect occlusion of the duct from stricture and a tendency toward the retention of pus and secretions.

Severe trauma lacerating the duct and producing a traumatic stricture with retention of the secretions may be followed by an acute inflammation, especially if the duct is already infected. I have treated one patient, a prostitute, who developed an acute suppurating cyst of the duct and gland after being kicked in the region of the gland by a drunken paramour. This woman had a gland which was already infected, as I have previously described, for the gland upon the opposite side was palpable. I have not tried to produce a laceration of the duct in the cadaver by a blow, and even if such is easily possible this case would not be conclusive, as stricture of the duct may have previously existed, and an increase of the inflammation or the effusion of a small amount of blood into the duct or acini of the gland might have acted to obstruct the duct, and thus produce the cystic retention which was necessary to initiate the process.

Inspissated secretions very often play a part in obstructing the duct, not acting alone, except in very exceptional instances, but in conjunction with stricture of the duct, the mode of formation of which has been previously considered.

The irritating discharges of cancer have been enumerated as among the causes of this form of disease of the gland. Without the encroachment of the cancerous tumor upon the duct or the development of papillomata or other growth to occlude directly or indirectly the lumen of the duct, I do not believe inflammation with cystic retention is likely to develop. A chronic inflammation of the duct, following an acute inflammation due to infection from a foul cancerous growth without retention of the secretions of the gland might be followed by stricture, which stricture interfering with the discharge of secretions and pus might be followed by this form of inflammatory disease, which we are at present considering.

I have mentioned the possibility of various growths encroaching upon the duct and obstructing it. This is a condition which we seldom see.

The commonest cause by far, as I have before suggested, of stricture of the duct is a prolonged gonorrhœal inflammation of the duct, and these varieties of stricture precede the development of this form of Bartholinitis, where there is an accumulation of pus and gland secretions in duct and gland.

Many have persisted in asserting that in these cases of inflammation the duct alone is involved in most instances. My own observations of these acute inflammations lead me to believe the contrary, and this is an opinion formed as the result of repeated extirpations of the gland during this condition, and I believe that further surgical experience of other men will go to prove the same.

The recognition of abscess of the gland could not be avoided, inasmuch as it is a common disease with striking and unmistakable symptoms, nevertheless a very imperfect understanding of the cause of the symptoms has existed. Writers seem to have exhausted their interest in expressing the opinion that suppuration and abscess are usually confined to the duct, and some have stated that we have superficial abscess of the duct and deep abscess of the duct. The reasons for such an opinion have not been expressed.

We are at present considering that form of the disease in which there is retention of pus and secretions in the duct or gland. We know when an infection develops in various parts of the body, that it will be from three days to a week before pus forms. Now this opinion has gained a footing, and wherever an inflammation is seen, it is

taken for granted that several days must elapse before pus forms. Here we have preceding the inflammation an accumulation of the infected secretions of the gland. Now these secretions by pressure upon uninfamed tissues cause but little discomfort. Quite a cyst may be present and cause no discomfort except during intercourse, but let the tissues about this cyst become acutely inflamed, and then the tension of the cyst will cause severe pain. This point I wish no one to misunderstand. In these cases cystic retention precedes all painful symptoms, and if we are merely to treat this case by palliative measures we need not poultice or wait for pus formation, for fluid has already accumulated, and the immediate evacuation of this fluid, as soon as the patient complains of pain, will relieve the tension upon inflamed tissues, and thus cause a subsidence of the pain.

THE COURSE OF THE DISEASE UNINFLUENCED BY TREATMENT.

Patients sometimes complain of a preceding chilliness, and in rare instances a distinct rigor. This is followed by malaise and a sense of discomfort in the genital region. This is accompanied by pain and tenderness over the site of the gland and duct, and usually within twelve or twenty-four hours the patient is complaining of severe pain over the gland. This pain is intense and lancinating, being badly borne as a rule, and causing much complaint. The color of the patient is often bad, the tongue is coated, and there is a febrile reaction. When the inflammation is at its height, the patient finds that even the change of position in bed is painful, and with loss of appetite and loss of sleep, the patient during the time is in quite an unhappy condition.

The first examination a few hours after the pain begins may reveal nothing upon inspection, but by palpation an exquisitely tender tumor will be felt beneath the labium. This tumor cannot be palpated freely, and it is not possible to grasp it even gently without causing much discomfort.

As the disease progresses, a tumor becomes apparent projecting toward the median line. It increases in size quite rapidly, and at the same time symptoms of inflammation of the external parts develop. The genitals over the tumor become acutely inflamed and this inflammation extends backward over the perinæum, so that an inflammation observed some days after its origin may be mistaken for an infection which has developed about the bowel and extended forward.

After a variable time the abscess ruptures spontaneously into the vagina or beneath the labium majus. The pus usually finds exit through sev-

eral openings, and then the severe pain subsides. The discharge of the contents of the cyst may occur by a giving way of the obstruction in the duct and in this way fistulæ may not form. Where this latter route of escape of the pus occurs, we are likely to find the duct again becoming occluded very early, and then we note an early recurrence of the acute symptoms in most instances.

After the discharge of pus and secretions, an examination will reveal in almost every instance an enlarged and somewhat tender gland. The suppuration continues and the fistulæ persist. In some cases the pus burrows backward into the perinæum and discharges into the rectum as well as into the vagina, so that we are able to find fistulous communications between these parts.

The pus discharged is usually fetid, and is capable of setting up an acute vaginitis or urethritis. I have had this condition under treatment where this acute inflammation has developed immediately after the discharge of the pus into the vagina. These reinfections are not to be looked upon lightly, as the woman may develop a uterine and annexal inflammation, which she has previously escaped.

This gland lies well back toward the perinæum, and an inflammation of it is not likely to be mistaken for pudendal hernia or cyst of the canal of Nuck or any other tumor of the genitals in front. Diffuse inflammation and phlegmon do not correspond either in symptoms or appearance to this condition. The acute inflammation is nearly always unilateral and the tumor projects markedly toward the opposite labia. Cysts without acute inflammation are unaccompanied by the severe pain and constitutional symptoms which manifest themselves in this condition.

(To be continued.)

Epidemic of Diphtheria in Cats.—The Orange (N. J.) Board of Health is preparing to investigate the cat population in the city with a view to preventing the spread of diphtheria. A large number of cats are known to be suffering with the disease at the present time. Many of these animals are the pets of children and the danger is great. Dr. G. Herbert Richards, president of the board of health and a member of the board of education, has said that he would advise all householders owning cats that have sore throats or are apparently suffering from difficult breathing to at once consult a physician.

The Medical Association of the District of Columbia, at its meeting on April 4th, elected the following officers: President, Dr. Clifton Mayfield; vice-presidents, Dr. D. Olin Leech and Dr. G. Brown Miller; secretary, Dr. D. W. Prentis; treasurer, Dr. Frank Leech.

A METHOD OF MEASURING THE X RAYS.

By MILTON FRANKLIN, M. D.,

NEW YORK,

LECTURER ON ELECTORADIOTHERAPY IN THE NEW YORK POLY-CLINIC MEDICAL SCHOOL.

It is scarcely necessary at the present time to say anything regarding the importance of a method for accurately measuring the energy of the x rays. The multiplicity of the attempts to this end made on all sides, speaks eloquently of its importance, and it is generally conceded that all experimental science depends ultimately upon accurate measurement. Of the many methods heretofore proposed for the measurement of the x rays, not one can be said to fulfill the loosest requirements of accuracy or expedition.

Until now, all methods have been based on one or a combination of the following principles:

1. The resistance of the tube as measured by that of an air gap in parallel.
2. The penetrability, as determined by the thickness of metal through which a fluorescent effect could be obtained.
3. The fluorescent effect, by comparison of a fluorescent screen with some standard light.
4. The photochemical effect as measured by photographic papers and the Holtzknecht radiochromometer.
5. The measurement of the amount of current in the secondary circuit of the induction coil or the static current.

The first method is of little or no value, on account of the possible variety of performances in a tube for a given resistance, and the obscure and inconstant relation between the performances of different tubes with equal resistances. Except by very complex mathematical expressions, no relation can be established between the resistance and performance of a tube, and the many variable factors in such equations as are made use of render the results extremely difficult of attainment.

The second method is generally made use of by employing the radiochromometer of Benoist. This consists of a casting of aluminum in the form of a circular train of steps, the height of each bearing a definite known ratio to that of the next preceding it. In the centre of the spiral is a sheet of silver of a given thickness. When the radiochromometer is attached to the fluoroscope, the number corresponding with the thickness of the step casting a shadow similar to that of the silver plate gives a rough estimate of the penetrability of the rays. The method is of value only in indicating the penetrability of the rays. The determination is necessarily rough, depending as it does on the personal equation of the operator. In consequence many differences of opinion arise and it is not possible

to compare the results of different observers with certainty.

The third method has not as yet been scientifically applied, though there is a possibility of its being of great value if a suitable photometer is devised, and the author is engaged in perfecting such an apparatus at the present time. Also there is a brief mention and a description of a forthcoming photometer for this purpose in *Le Radium*, No. 4, for October, 1904.

The fourth method, in its most popular application, is based on the change in color produced in certain salts by absorption of the rays. In practice a small quantity of a test reagent is applied to the skin near the lesion to be treated, where it can be acted on by the rays. This reagent is frequently removed and compared with a standard tint found on a scale of graduated tints, having arbitrarily chosen numbers. When the test reagent has assumed the desired color, the treatment is terminated. The method while apparently capable of some accuracy in hypothesis, is subject to grave errors in practice. Total dependence is placed in the matching of the colors by the eye, and this presents serious difficulties, especially as it must be done in subdued light, to lessen the danger of an incorrect result from the light. The numbers on the standard scale are purely arbitrary and bear no known mathematical relation to each other, so that comparison of results can have no real value. Besides this there is no convenient application to radiography, and the method offers no means of rapid adjustment. The uncertainties of the method are so numerous and considerable as to have prevented its general use, and recently while in Paris, the writer was informed that the apparatus is no longer manufactured and that the method generally had fallen into disuse.

The proposed method of using a photographic paper and having the rays traverse it before reaching the lesion, is scarcely possible. It presents at best only a means of estimating the quantity of rays which *have* acted, and offers no aid to regulating the quantity which it is desired *shall* act. It is, therefore, of little or no use.

The fifth method is altogether misleading and is based on a false assumption. As can be easily proved there exists no discernible or demonstrable relation between the x rays produced and the current indicated by the reading of a millimeter in the circuit. Experiments made by the writer show that there may be a reading indicating that the current is less than zero, or that it is reversed, and that there may be quite potent rays coming from the tube. The many uncertainties and contrary conditions in the application render it impossible to obtain accurate results with this method. A merely

theoretical consideration of the subject renders evident its sophistry, but I cannot spare the space necessary to discuss it here.

The method I herein present is based on the power of the x rays to ionize the gases through which they travel. This quality has been known for some time but has not, so far as I have been able to ascertain, been systematically used to measure the intensity of the x rays. The method, excepting for necessary modifications to make it conform with the special requirements of the x rays, is substantially analogous to that now commonly employed to measure the radioactivity of the radioactive substances. Air is rendered a conductor of electricity by the ionizing agent and measurement of the amount of current flowing through it under given conditions gives an absolute index of the activity of the radiation.

With ordinary care, this method is capable of great accuracy, and discrepancies in the results of different observers, due to personal equation, are negligible. The measurements may be made, as is done for radioactive substances, in laboratories, with some form of Lord Kelvin's quadrant electrometer, but such apparatus requires much space, a battery or other generator capable of maintaining a constant E. M. F. of at least 700 volts, and much time and skill in its operation. Also the condition of the instrument varies from day to day and its exact constant must be frequently determined.

With an electroscope, on the other hand, of the gold leaf pattern, the relative activities of two radiations may be compared with great accuracy and expedition, and if one of them is the standard unit of activity or bears a known ratio to the standard, the value of the other, in terms of the standard, will be readily deducible. It is necessary only to charge the electroscope by applying a rod of vulcanite, sealing wax, resin, or other suitable material, which has been previously electrified by friction, and then to time the transit of the filament under the influence of the rays. The rate of discharge will vary directly as the activity of the radiation.

All computation with consequent delay is eliminated, and the whole process need not occupy more than ten or fifteen seconds. The electroscope may be charged and the rays allowed to enter only at the instant when desired during the exposure, by means of a ray proof shutter at the back of the instrument.

In order to make clear the working of this method, it will be necessary to briefly review the ionization theory of gases.

J. J. Thompson and Rutherford (*Phil. Mag.*, November, 1896) explained the phenomenon of the discharge of both positively and negatively charged

bodies, in the vicinity of a Crookes's tube on the assumption that the x rays produced in the gas surrounding the charged body, positively and negatively charged carriers. These carriers which are now universally called ions, travel in an electric field, with a velocity directly as the strength of the field.

Thus, if we have two parallel plates, A and B (Fig. 1), the one positively, and the other negatively charged, and x rays are caused to traverse the air

FIG. 1.

between them, ions will be generated therein, which will travel toward the plates with a velocity proportional to the strength of the electric field, the negative ions traveling toward the positively charged plate and the positively charged ones in the opposite direction. The number of ions produced a second under the influence of the x rays will depend upon the nature and pressure of the gas present, the distance between the plates, and will vary directly as the activity of the ionizing agent. In what follows we shall regard the gas between the plates as atmospheric air under ordinary pressures, unless otherwise stated.

If there is no electrification upon the plates and consequently no difference in potential between them, there will be a recombination of the ions as soon as produced. The rate at which this recombination takes place has been experimentally determined to vary as the square of the number present. Owing to the absence of a definite motion, on account of there being no electric field, the number which recombine will be large and will ultimately balance the number produced. Now when a small potential difference is established between the plates, the ions begin to move in the electric field and, as the rate of production is constant for any given ionizing agent, the number of recombinations lessens in proportion to the number which reach the electrified plates. As the potential difference is increased, the speed of the ions is proportionately

increased, and the number of recombinations decreased. A stage is finally reached where the speed is so great that the ions do not have time to recombine in passing and all of them travel across the field and reach one plate or the other. After this point is attained, no increase in the potential difference between the plates can cause an increase in the amount of current flowing between them, it being borne in mind that the charge carried by an ion has a constant value. An increase can be affected only by increasing the rate at which the ions are produced.

In brief, the quantity of gas between the plates and the activity of the ionizing agent will determine the maximum amount of current that can pass between the plates, the potential difference between them being insignificant after it has reached the value sufficient to cause all of the ions to carry their charges to one or other of the plates as soon as they are produced. The value of the maximum current that will flow through an ionized gas under any potential is called the saturation current on account of the resemblance of its graphical representation to that of the magnetic saturation curve of iron, and it is the measure of this saturation current upon which comparative determinations depend.

The rays given off by uranium are analogous, with respect to their photographic and electrical action, to those from the Crookes's tube, but inestimably more feeble. Nevertheless, so delicate an indication of the presence of radioactivity is the ionization of air, that by specially designed apparatus, an activity of one ten thousandth, or even one one millionth, that of uranium may be detected.

The electroscope which has been devised for the measurement of the x rays comprises an electrical system and a shell in which it is isolated. The function of the latter is to confine the action of the rays to a particular portion of the system. If it is desired that the results be comparable, it is absolutely necessary that the instruments be identical in design and dimensions. Details and proportions of this instrument are shown in Fig. 2, and the figures in the text refer to the cut.

The shell is of brass, one eighth inch thick, four inches square inside, and seven and one eighth inches long. The diaphragm, I, is of hard rubber, one fourth inch thick, and divides the inside of the shell into two compartments, the lower of which is two and one half inches high. The window, E, in this compartment, is two inches in diameter, circular, and closed with an air tight hard rubber blind, one sixteenth inch thick. The space, S, between the ends of the rods, C, D, is at the exact centre of the compartment and is one quarter inch long. The lower rod, D, is one quarter inch in diameter and communicates with the shell by means of the metal bottom on which it is mounted. It is thus kept at a potential, zero, by being in electrical communication with the earth. The upper rod, C, is one quarter inch in diameter and passes through the

FIG. 2.—Plan of electroscope.

diaphragm, I. It is fastened at its upper extremity, into the rubber plug, F, and does not communicate with the outer air in any manner.

The filament, B, is fastened to the rod, C, at a point two and one eighth inches from the diaphragm, I; it is one quarter inch in width, and has a free length of one and three quarter inches. It is made of thin aluminum foil. In the upper compartment there should be glass windows at the sides to allow of illumination; the dimensions are relatively unimportant.

The charger consists of the rod, G, passing through the cover of the shell. The hard rubber handle, K, permits of turning the rod, G, and bringing the brass spring, J, into contact with the rod, C; when the handle, K, is released, the rod, G, resumes its former position, by means of a spring and breaks the connection with the rod, C.

The tube, M, serves to limit the field over which the filament moves during the period of the reading. Its dimensions and position are of the extremest importance in rendering the instruments comparable. The length between the diaphragms, N, L, should be six inches. The diaphragm, N, has a diameter of seven eighths inch and the diaphragm, L, is one eighth inch in diameter. The tube is fastened to the wall of the shell and so placed that the upper limit of the field corresponds with the terminal side of the angle 350° , i. e., the filament first comes into the field after it has traversed the angle— 10° . The transit of the needle from the time it enters the field till it disappears beyond the inferior limit of the diaphragm will vary in speed directly as the intensity of the x radiation, and inversely as the square of the distance of the

tube from the radiometer. The position of the filament and its transit is shown in Fig. 3. The filament during its transit describes an angle in the negative direction in the fourth quadrant.

The electroscope may be mounted on a stand rendering it movable about the room. In the model shown in Fig. 4 there is a large shield of some metal

FIG. 3.—Position of reading tube and transit of filament.
() = 350° ; $\phi = 10^\circ$.

impervious to the rays, which is placed at the back of the instrument and which protects the operator from the action of the rays while making the observation.

The counting may be done with a stop watch, a metronome, or other convenient device.

The following details of design are the result of experimental consideration:

i. Having the lower chamber closed, precludes the

possibility of the ultraviolet rays causing the discharge. As an extra precaution, no zinc should be used in the construction.

2. The lower compartment should contain a fragment of calcium or a vessel of sulphuric acid or other drier for the purpose of maintaining the air within at a constant condition of dryness. If this precaution is observed, the chamber will not need attention for months. The condition will not vary appreciably and changes in the rate of ionization, due to variations in the amount of moisture in the atmosphere, will be negligible.

3. The thickness of the shell should be such that no appreciable amount of rays enters. In this way the leak is confined entirely to the space between the plates in the lower chamber, and consistent performance is thus assured.

4. The arrangement of the charging system is such that there is no communication between the charged filament and the surrounding air, so that the discharge of the electroscope takes place only when the rays are allowed to enter the lower chamber. The instrument may be left charged in the vicinity of an operating tube without discharging.

5. The tube is placed at the front of the electroscope and the window for the rays to enter at the back. In this way, with the help of the shield before spoken of, the operator is not exposed to the action of the rays.

In making use of the instrument it should be remembered that, as the rays emanate from a single point on the target, their potency will vary inversely as the square of the distance. Thus if it is desired to know what the energy of any ray is at a distance d_1 from the tube, and it is known from the electroscope placed at the distance, d_2 , that the energy is e , then the energy x , at d_1 , can be found from the equation:

$$\frac{x}{e} = \frac{d_2^2}{d_1^2} \dots \dots \dots (1).$$

The result so obtained will not be strictly accurate, however, because of an error introduced by the absorptive influence of the atmosphere on the x rays. It is a variable which must be considered. If the power of the radiation was inversely proportional to the square of the distance, we could plot the relation between the distance of the tube from the electroscope, and the time of discharge, on an ordinary paraboloid curve, as in Fig. 5, where the solid curve represents the one whose equation is,

$$y = x^2 \dots \dots \dots (2).$$

The distance of the tube is plotted as abscissa while the time of discharge is plotted as ordinate.

Experimentally, however, it is found that at any distance, x , the time of discharge, y , instead of being exactly equal to x^2 , is equal to kx^2 , where k is some constant greater than unity: i. e., instead of the time of discharge varying directly as the square of the distance, it is found to take longer than the equations call for. In consequence, we get a curve similar to the dotted line in the figure. This additional time is found to vary with the condition of the atmosphere through which the rays pass but, for any condition, bears a definite relation to the indicated time. The variation while small, even between the extremes of midsummer and mid-winter, is still appreciable and demands consideration. To determine the exact value of the constant k would be impossible without the aid of very elaborate calculations, and by neglecting it, the results obtained in different places would agree only roughly. To avoid all the uncertainty introduced by this variable factor and to render at once com-

FIG. 5.

parable all readings, it is only necessary to measure the energy of the rays at the distance from the tube at which they are to be used. By this simple expedient the actual strength of the rays at the point of application is found, no consideration being given to the quantity absorbed before arriving at that position. The number of seconds which it requires for the filament to traverse the field is the coefficient of the strength of the rays, all calculation and variation due to atmospheric absorption being at once eliminated.

The application of the instrument is as follows:

1. The electroscope is charged by having brought into contact with the knob, a rod of vulcanite which has been electrified by friction. The knob is brought into communication with the filament, while the vulcanite is in contact, and released as soon as the filament has assumed a horizontal position.

2. The electroscope is brought to the same distance from the tube as the patient or plate (in any position) and while the tube is running, the shutter is opened

and the time in seconds, occupied by the filament in transit, is noted. The number of seconds is the exact coefficient of energy of the rays, and when compared with any other reading made under any circumstances whatever, with a similar instrument, the ratio of energy of the two radiations will equal that of the two times.

112 WEST FORTY-SEVENTH STREET.

A REVIEW OF THE TREATMENT OF INFLAMMATORY CONDITIONS OF THE THROAT BY IRRIGATION AND A DESCRIPTION OF A NEW IRRIGATOR TIP.

By EDWARD L. KELLOGG, M. D.,
NEW YORK.

During the several years of my connection with the Hospital for Scarlet Fever and Diphtheria Patients, I have received many inquiries from physicians in New York and elsewhere concerning the methods adopted there for treating throat infections in scarlet fever and diphtheria.

The statement that we use saline irrigations has been followed in many cases by a request for details. A review of the *modus operandi*, therefore, may not be out of place, although the course pursued is not a new one.

The usual forms of amygdalitis and pharyngitis may be treated effectively in the same way.

Normal saline is the solution ordinarily used. Occasionally when the throat is dry and glazed, a solution of sodium bicarbonate (one tablespoonful to a pint of water) is preferred to soften tenacious mucus or start secretion.

Boric acid, potassium permanganate, and other antiseptic solutions possess no apparent advantage over the salt water which not only has a soothing and cleansing effect, but will do no harm even if a considerable quantity is swallowed while the patient is being "broken in" to the treatment.

The solution is made as hot as it can be borne without discomfort, usually 110° F. at the start with a gradual increase to 125°.

The quantity used is about two quarts; sometimes, however, it is necessary to diminish the amount until the patients learn to let the water flow out of the mouth without exhausting themselves by gagging and straining.

The severity of the infection plus the ability of the patient to stand the irrigation determine the frequency of the treatment. Severe cases as a rule are irrigated every two hours from six a. m. to midnight.

The patient, protected by a rubber sheet, is

turned on one side with the cheek resting on the edge of a pus basin, and the head is lowered slightly by removing the pillow. (Infants are prepared as for intubation by wrapping them from the shoulders to the feet in a strong sheet fastened firmly at the shoulders, elbows, wrists, knees, and ankles.) A fountain or Davidson soft rubber bulb syringe is used. The straight tip of the syringe is introduced into the mouth in the median line and carried back to the base of the tongue, which is held down so as to expose the back of the throat. The solution is then directed with considerable force against the pharynx, or the part of the throat from which we wish to dislodge the membrane. When the mouth is filled, the tube is compressed with the finger, and the patient is allowed to expel the solution into the basin. This process is repeated until the treatment is finished.

The effect of the treatment described is to relieve pain, dislodge membrane, and wash away thickened mucus more thoroughly than by any other means with which I am familiar.

In bad cases, particularly those in which the nasopharynx is extensively involved, the nose is also irrigated with the same solution. A conical tip which plugs the nostril tightly is employed, or a catheter is passed through one nostril to the

nasopharynx. The latter method, although slightly less efficacious, is adopted to minimize the danger of ear infection, which is considerable in all nasal irrigations.

The tips supplied with the syringes are not well adapted for the work of throat irrigation; they are too short and do not offer a sufficiently broad surface to satisfactorily depress the tongue.

On this account I have devised an irrigator tip which is now in use in the Hospital for Scarlet Fever and Diphtheria Patients, and which I have used in private practice with much satisfaction.

This tip may best be described by repeating the specifications which I have given for the manufacture of it.

Make irrigator tip of

Dr. Kellogg's new Irrigator tip.

hard rubber, seven inches in length, a straight canal extending the entire length of same, size seven, French scale, one end conical in shape to fit easily into the rubber tube of the syringe with a groove above to keep the tube from slipping; the outer end flattened and curved downward to form a tongue depressor three quarters of an inch wide.

The tip is small enough to be used in the throat of a child and yet satisfactorily controls the tongue of an adult. It is long enough to prevent the hand of the operator from interfering with inspection of the throat.

The cuts convey a good idea of the instrument when completed.

104 WEST FIFTY-EIGHTH STREET.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 756.)

Hæmoantitoxine is a preparation of Maragliano's tuberculosis antitoxine in combination with alcohol and glycerin, flavored with aromatics. It forms a clear solution of a wine red color of agreeable taste. It is given as a prophylactic against tuberculosis in tablespoonful doses four times a day before eating. It is made at the laboratory of the Institute for Infectious Diseases, Genoa, Italy.

Hæmolin is the name given to a mixture of oxyhæmoglobin and maltose.

Oxyhæmorrhoidin is a name that has been incorrectly applied to hæmorrhoidin, the name of a tablet which owes its medicinal activity to the active principle of what is described as extract of *pantjansona*, a plant which it is asserted is indigenous to Asia. The tablet has a basis of chocolate and sugar. (We have been unable to place any plant bearing this name.—Ed.)

Heritine Marpmann, which must not be confounded with the alkaloid heritine obtained from *Heritiera japonica*, appears to be a dilute alcoholic solution of the crude alkaloid heritine. It contains from 45 to 46 per cent. of alcohol and is devoid of any special taste or odor, forming a clear solution. After concentration by evaporation the solution gives the reaction for alkaloids; the residue contains small amounts of albumen and mineral matter.

Hæmapeptone is represented to be a solution of albumose peptone combined with hæmatin in a mixture of alcohol, glycerin, and aromatics. It is asserted to possess nutrient nitrogenous properties and may be administered by the mouth or by rectum.

Hæmec Tablets contain hæmatin, an organic iron preparation, grain $\frac{1}{4}$; nux vomica, grain $1\frac{1}{8}$; arsenous acid, grain $\frac{1}{120}$. It is recommended in malaria and other ailments characterized by impoverishment or loss of blood.

Hæmostyptic, Brünninghausen, is a preparation of the active principles of ergot and golden

seal, which is recommended in hæmorrhages, in 30 drop doses, four times a day.

Herniarin is a new active principle obtained from the leaves of *Herniara glabra*. It is soluble in absolute alcohol, but insoluble in ether. When triturated with sulphuric acid the crystals turn yellow, later pink, and finally dark red. On boiling with water the product is split into glucose and herniariac acid, an acid which is regarded by some as the active principle of the herb itself, which is used in the treatment of calculi in the kidney, Bright's disease, etc., chiefly as a diuretic.

Histosan is a combination of guaiacol with egg albumen, which is put up in syrup and powder form. It is intended for the treatment of tuberculosis, the dose of the syrup being from a teaspoonful to a tablespoonful three to four times daily and of the powder 4 to 8 grains.

Hals's Pastilles consist of 2 grammes of masses of guaiac resin and white sugar, with a certain quantity of anæsthesin, menthol, and rose oil. They are said to be effective in the treatment of amygdalitis and similar throat affections.

Hippol is the trade name adopted for methylene hippuric acid, which occurs as colorless prismatic crystals, without odor or taste and only sparingly soluble in water. It is recommended as a urinary antiseptic in the treatment of bacterial diseases of the urinary organs, in doses of 24 grains four times daily. The antiseptic action of this compound is said to be due to the setting free of formaldehyde during the processes of metabolism.

A Public Library for the Blind.—A recent issue of the *Evening World* draws attention to a charity that must appeal strongly to any one who gives it more than a moment's thought. The *World* says: A public library for the blind has been opened in Brooklyn. It starts with 400 books, printed not with letters in ink to be read with the eye, but with the punctured characters for the trained and sensitive fingers of the blind. The library is located at Fourth Avenue and Pacific Street, and all blind visitors will be welcome. Although the books are not many in number, they take up a great deal of space. Books for the blind cannot be printed on thin paper, and the punctured characters must not be compressed, or they become blurred and more difficult to read. The Bible alone takes up three feet of shelf space. The blind readers who have been consulted as to the kind of books they most want express a preference for light literature. They prefer books telling of sunshine and outdoor life, with vivid descriptions of the scenes which they cannot see and the things of which their loss of sight deprives them of first hand knowledge. A library like this will bring more happiness than many great libraries for those who can read. The cost of preparing books especially for the blind is so great that the purchase of single copies by the blind is rare, and a library which gives them access to current literature will do much to bring into their lives some of the sunshine which they cannot see.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, APRIL, 22. 1905.

THE PHILADELPHIA CONFERENCE OF ANATOMISTS.

On April 11th and 12th there took place in Philadelphia a conference of ten prominent American anatomists who had been invited by the Wistar Institute of Anatomy to consider, with the managers of the institute, the question of increasing its usefulness to American anatomists by establishing relationship with the individual anatomists of the country, with the Association of American Anatomists, with the *American Journal of Anatomy*, and with similar institutes abroad, also the question of establishing an advisory board of anatomists of the institute, with ten or more members selected from the leading anatomists of the country. The following anatomists were present at the conference:

Dr. Lewellys F. Barker, professor of anatomy, University of Chicago; Dr. Edwin G. Conklin, professor of zoology, University of Pennsylvania; Dr. Henry H. Donaldson, professor of neurology, University of Chicago; Mr. Simon H. Gage, professor of embryology, Cornell University; Dr. G. Carl Huber, professor of embryology and histology, University of Michigan; Dr. George S. Huntington, professor of anatomy, Columbia University; Dr. Franklin P. Mall, professor of anatomy, Johns Hopkins University; Dr. J. Playfair McMurrich, professor of anatomy, University of

Michigan; Dr. Charles S. Minot, professor of embryology, Harvard Medical School; and Dr. George S. Piersol, professor of anatomy, University of Pennsylvania. General Wistar, the donor of the institute, representing the board of managers, after expressing his pleasure at having such a distinguished body of men present, spoke of the organization of the institute, its objects, its resources, and its probable future. Dr. M. J. Greenman, director of the institute, followed with a short address outlining the work which he thought might be accomplished by the conference.

The anatomists were called upon to consider what special lines of work the institute might best undertake. They were also requested to consider the possibility and advisability of establishing a central institute of neurology to make use of the Wistar Institute as its working base and acquiring relations with the committee appointed by the International Association of Academies for Brain Investigation. Attention was called to the achievements made possible by cooperation with an institution organized and endowed for research anatomy. The organization of an advisory board of anatomists for the institute was suggested as a possible means of accomplishing the most work for the greatest number.

The conference then organized and elected Dr. Charles S. Minot chairman and Dr. M. J. Greenman secretary. A discussion brought out the unanimous opinion that the Wistar Institute of Anatomy offered exceptional facilities for all investigators in this branch of science. It was thought that research material might be collected and prepared there, especially neurological and embryological material, in such a way as to save much time to the interpreter; and that original preparations which had been studied, and were therefore of much greater value, should be deposited in the Wistar Museum for the future use of students who wished to review the work. The reproduction of models was suggested. The importance of organized effort to collect and properly prepare the vast amount of anatomical material which usually went to waste and the desirability of its immediate use while fresh were emphasized. The establishment of agencies in va-

rious localities, with skilled preparators in charge for the collection of material, was suggested. It was made plain in the course of the discussion that the advanced museum work which the institute was striving to do was inseparable from investigation. It was considered that the pursuit of a well defined line of research was necessary for the proper collection and preparation of materials. Neurology, embryology, and comparative anatomy were discussed as the broad fields of work to be developed, and it was thought that neurological research should be the first to receive attention.

A committee, consisting of Dr. Minot (chairman), Dr. Donaldson, and Dr. Mall, reported an outline of the principal objects of the institute, and recommended that an advisory board of ten be appointed. General Wistar thereupon expressed the approval of the Wistar Institute as to every detail of the recommendations and asked the ten anatomists present if they would become members of a permanent advisory board of anatomists of the institute and proceed to organize and appoint such committees as had been recommended. He explained that he represented the sentiment of the members of the board of managers present, and he would assume authority for the creation of such a board and the appointment of its members, and he had no doubt that the creation of the advisory board of anatomists and the personnel of its membership would be officially confirmed by the board of managers at its next meeting. The members of the conference consented and the advisory board was organized by electing Dr. Charles S. Minot as chairman and Dr. M. J. Greenman as permanent secretary. A meeting of the board of managers held on April 18th officially confirmed the action of its representatives at the conference.

The advisory board proceeded to appoint the following committees: On neurology and the establishment of relations with the International Association of Academies, Dr. Barker, Dr. Donaldson, Dr. Mall, Dr. McMurrich, and Dr. Minot—this committee to elect its own chairman. On the relations of the Wistar Institute to American anatomists, Professor Gage (chairman), Dr. Pierson, and Dr. Huber. On comparative anatomy

and embryology, Dr. Huntington (chairman), Dr. Conklin, and Dr. Mall.

At the close of the meeting Dr. Barker called attention to the unusual procedure of an endowed institution offering its facilities in such a liberal manner to the workers in the science and calling upon them to advise methods of development which would be advantageous to both the institute and themselves.

The enlightened course pursued by the institute in this matter and the cordial cooperation of the anatomists who took part in the conference are certainly of great promise for the prosecution of anatomical research in this country.

THE VALUE OF EVIDENCE.

Not long ago a representative of this journal saw a distinguished master of modern magic make a demonstration of the art at an uptown theatre. The most forcible impression derived from the experience was that human testimony is an extremely fallible thing. To one having some knowledge of the principles upon which modern magic is based it is truly amazing to hear an account of any trick given by one of the uninitiated; the essentials upon which the success of the trick depends are omitted and the actual deception which the artist has been at pains to create is dwelt upon in detail. Careful contradiction of the narrator will elicit the most vehement reiteration of what he supposed he had witnessed, and a further expression of doubt will lead to a belief on his part almost fanatical in its nature—a veritable "faith, the evidence of things not seen."

As Hume pointed out, there is nothing intrinsically impossible in miracles, and the only justifiable disbelief in their occurrence is founded on the unreliable character of the testimony adduced to prove their occurrence. Members of our profession have, however, made deplorable laughing stocks of themselves more than once when certifying as to the "unexplainable" performances of "magnetic women," sealed letter readers, and others.

Testimony, to be of value, must be really expert testimony. When persons who claim supernatural powers are to be investigated, the invited committee of doctors might well add to their

number a competent modern magician and possibly the manager of a dime museum. The shock of the temporary association would be more than compensated for by the illuminating comments and conclusions of the latter.

The lesson to the physician as an individual is that he should discount heavily the history and account of symptoms given by the relatives of a sick child and even those made with painful attempts at accuracy by an adult concerning his own ailments. The objective examination may be made first and thoroughly if the patient can be kept quiet long enough, and his subsequent statements should be depended upon more to shed valuable light on his mentality than to help materially in the diagnosis.

THE PREVENTION OF CONCEPTION.

In France there has lately been under discussion the question of the justifiability of preventing conception, not only for the preservation of the woman's life, but also for reasons that we cannot look upon as founded on anything more serious than considerations of convenience. The discussion is in the form of letters written in reply to a circular of inquiry by Dr. Klotz-Forest, published in the *Chronique médicale* for February 15th. That individual does not seem to have asked for any justification of anybody's advocacy of preventing conception for social or personal reasons, but he does appear to have imposed on the opponents of the practice the burden of sustaining their contention.

A few of the replies are published in *Médecine orientale* for March 25th. They are by Dr. Grasset, of Montpellier, M. Lucien Descaves, Dr. Paul Achard, Dr. Francis Bleynie, President Magnaud, of Château-Thierry, and Madame Odette Laguerre, editor of the *Fronde*. All these persons, except Dr. Grasset, uphold the practice, but it is worthy of remark that one of them, Dr. Bleynie, makes it a *sine qua non* that the means employed shall consist solely in abstinence from coitus. By implication Dr. Bleynie limits his approval of the practice to cases in which coitus would be injurious to the husband or parturition exceptionally dangerous to the wife, and he seems to feel confident that men and women will observe con-

tinence for such reasons—the man on the woman's account and the woman for the man's sake. But it may be that he is sarcastic throughout.

Dr. Grasset pricks the bubble of conscience salving out of regard for apprehended danger to the wife, and undoubtedly he expresses the feeling of the great majority of physicians. As he puts it, if the justifiability of preventing conception in the interest of the wife's health should be conceded, married couples will feel at liberty to prevent it in case the physician cannot guarantee that childbirth will be quite free from peril to the woman, which of course no physician can do. One may share Dr. Grasset's dread of the consequences of such a free and easy shifting of responsibility upon the physician, and yet not deny the propriety of preventing conception in cases of exceptional danger to the woman.

THE CLAMP VERSUS THE LIGATURE FOR HÆMORRHOIDS.

Nothing contributed to current literature for a long time on this special subject has been so clean cut, decisive, and worthy of consideration as the article by McBurney in a recent issue of this journal. His ground is this: Make a clean dissection of the tumor; follow it up to its pedicle; tie; amputate; close the incision by suture; and strive for primary union.

To show how near we are together, my own rules can be formulated as concisely. Make a clean dissection of the tumor, follow it up to its pedicle, grasp with artery forceps, amputate and cauterize rather than ligate the stump, and wait for healing by granulation rather than hope for union by first intention.

Really, we are getting pretty near together. McBurney thinks the cautery rather old fashioned and primitive compared with the ligature, but the cautery is, I believe, still in favor in sealing the stump of an appendix and is preferred by many to the ligature. It is preferred by me to the ligature in cases of hæmorrhoids, but this may be only a preference.

McBurney's operation is thoroughly scientific and probably fully as painless as mine. My own is as thoroughly scientific as his, and probably as painless. The question is, then, reduced to this:

Can he get union by first intention in a majority of cases? I have given up trying to do so, and therefore trust entirely to union by granulation.

But the main point is this, which seems to be agreed upon both by McBurney and myself, that hemorrhoids are vascular tumors, to be treated as such, dissected out, isolated, strangulated, amputated, cured, and that to do this it is not essential to amputate the rectum. This point having been made plain, both by McBurney on his side and by myself, much has been gained.

Whitehead's amputation of the whole "pile-bearing area" goes into history. The clamp operation as applied to skin, hæmorrhoid, and everything in grasp, has never been taught; and has been the damnation of the method. If there was no better method than this, McBurney's operation would come out far in advance. The only trouble with the clamp operation is that so few men who practise it really have the faintest conception of its proper technique; and the instruments are in themselves misleading. My own "clamp" in the future will be an ordinary broad bladed artery forceps, and by this means something may be done to make it plain that to operate on hæmorrhoids by the clamp and cautery method does not require a blacksmith's vise or a jack screw.

CHARLES B. KELSEY.

RADIUM IN THE TREATMENT OF CANCER.

Sensational articles appeared in several of the daily papers on April 19th giving details of the treatment and cure of a case of cancer at the Flower Hospital by means of radium. In the course of the article credit for the cure is given to Hugo Lieber, who requests us to state, as will be seen in our news columns, that his only connection with the matter was the preparation of celluloid needles coated with radium, which were made at the request of Dr. Piffard, who stated that he desired to make use of them in a case of cancer. Mr. Lieber has never seen or treated the patients. The particular method of employing radium in the case in question was described at some length by Dr. Piffard in an address delivered before the Medical Society of the County of New York on March 27, 1905, when he also exhibited the radium coated needles. While the results obtained by Dr. Piffard have been quite satisfactory so far, he does not consider that a sufficient number of cases have been treated to justify any final conclusion as to the real value of

radium applied in this manner, and for that reason he has not as yet made any formal report of the results of this treatment, and deprecates the fact that so much undue publicity has been given to the particular case referred to in the lay press.

A PREPOSTEROUS PIECE OF PROPOSED LEGISLATION.

There is now before the legislature of the State of New York a bill which seeks to endow magistrates with the power to commit certain offenders for a course of treatment in the Oppenheimer Institute, and seems virtually to command them to exercise the power—the institute's remuneration to be provided for at the rate of \$25 for each person so committed. Such colossal effrontery has never before been witnessed, so far as we know, even in legislative halls.

THE INDIANA CIGARETTE LAW.

There seems to be no fad, no matter how ridiculous, that cannot be made acceptable to the legislative mind, especially if it is adroitly managed. But there must be some limit to the fatuity that legislators are willing to display, and we should say that that limit had nearly been reached in the recent enactment of the Indiana cigarette law.

THE CRESS AS AN ANTIDOTE TO NICOTINE.

At a recent meeting of the Paris Academy of Sciences (*Semaine médicale*, March 22nd) M. Zalackas expressed the opinion that the expressed juice of the cress was preeminently an antidote to nicotine, and he related an experiment supposed to show its efficacy in the case of a rabbit poisoned with nicotine. The experiment would be a little more convincing if the intravenous injection of cress juice had not contained caffeine.

Cincinnati City Hospital.—The following have secured positions as internes in this institution after a severe competitive examination: Dr. T. P. Scott, of Carlisle, Ky., Miami College; Dr. E. O. Schwartz, of Kings Mills, Ohio, Ohio College; Dr. A. T. Heavenrich, of Cincinnati, Miami College; Dr. L. W. Stacey, of Norwood, Miami College; Dr. G. W. McCoy, of Cincinnati, Miami College; Dr. Miriam C. Schaar, of Cincinnati, Miami College; Dr. Martin H. Urner, of Cincinnati, Miami College; Dr. A. W. Foertmeyer, of Cincinnati, Ohio College. Four alternates were named, as follows: Dr. Walter H. Bush, of Madisonville, Ohio College; Dr. Leon G. Tedeschi, of Cincinnati, Ohio College; Dr. Paul D. Espey, of Rising Sun, Ind., Ohio College; Dr. R. E. Gaston, of Montgomery, O., Miami College.

News Items

Society Meetings for the Coming Week:

MONDAY, April 24th.—Medical Society of the County of New York; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, April 25th.—New York Medical Union (private); Metropolitan Medical Society; Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Va., Academy of Medicine and Surgery; Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private).

WEDNESDAY, April 26th.—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society; New York Dermatological Society (private); Auburn, N. Y., City Medical Association; Berkshire, Mass., District Medical Society (Pittsfield; annual).

THURSDAY, April 27th.—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Mass., Society for Medical Improvement (private; annual); Pathological Society of Philadelphia (conversational); Church Hill Medical Society of Richmond, Va.; New York Celtic Medical Society.

FRIDAY, April 28th.—New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending April 15, 1905:

	April 15.		April 8.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	473	9	422	13
Diphtheria and croup	325	31	359	27
Scarlet fever.....	260	11	259	7
Smallpox	2	1	4	..
Chickenpox	180	..	94	..
Tuberculosis	372	178	441	201
Typhoid fever.....	16	6	26	13
Cerebrospinal meningitis.....	182	117	191	110
	1,710	350	1,776	371

An Ellis Island Hospital.—By the awarding of a contract for the construction of an island in New York harbor, the immigrant station at Ellis Island is assured of another important addition in the form of a hospital for the treatment of contagious diseases, which, it is intended, shall be the finest institution of its kind in the world. The cost of making the island will be \$119,000.

The Facts Concerning a Sensational Radium Cure Newspaper Story.—The following letter explains itself:

"TO THE EDITOR:

"Sir.—I note that the daily papers of April 19th contained sensational articles attributing to me the treatment and cure of a case of cancer at the Flower Hospital, in reference to which I beg leave to say that I have never been in the Flower Hospital in my life and that the statements contained in these various articles are in the main false and wholly misleading. My only connection with this matter was the preparation, some months ago, of some celluloid needles coated with radium, which were made by me at the request of Dr. Piffard. For about two years I had been trying to obtain radium in such form as to overcome the obstruction of the container so as to make the *alpha* rays available for practical use, which I finally succeeded in doing by what I have termed radium coating. This only is the novel feature of my invention. My only connection with

the case was the preparation of the radium coated celluloid needles at the request of Dr. Piffard, who desired to try them in a case of cancer. I have never seen any of the patients nor treated any of them, and if any credit is due for the use of these needles prepared by me it is to Dr. Piffard.

"Yours very truly,

"HUGO LIEBER."

Academy of Medicine.—The Section in Laryngology and Rhinology will meet on Wednesday, April 26th, at 8.15 p. m. Order: Presentation of Cases: 1. Report and Presentation of a Case of Thyrectomy with Subsequent Laryngectomy for Cancer of the Larynx, by Dr. Walter F. Chappell; 2. Set of False Teeth, Which Had Remained in the Oesophagus Six Weeks, with Radiograph of Chest and Neck Showing Teeth in Position, by Dr. Robert C. Myles; papers: Eucaine Lactate as an Anæsthetic on the Nose and Throat, by Dr. Thomas J. Harris; a short paper on Instruments and Their Use in Intranasal Operations on all the Nasal Accessory Sinuses, with Special Reference to New Mallet Chisel that cuts from the vital parts with Rotary and Punch Principles, by Dr. Robert C. Myles; Specimens and New Instruments: An Unusually Large Postnasal Fibrous Polypus, by Dr. William W. Carter; Set of Tonsil Scissors with the Pressure Created Near the Distal End, by Dr. Robert C. Myles. Lewis A. Coffin, M. D., chairman; Lee Maidment Hurd, secretary, 15 East Forty-eighth Street.

The Section in Obstetrics and Gynecology will meet on Thursday, April 27th, at 8.15 p. m. Order: Presentation of Specimens: (a) Four Cases of Ectopic Gestation Presenting Unusual Clinical Features; (b) Two Specimens of Fibroid with Colloid Degeneration, by Dr. L. J. Ladinski; paper: The Effect of X Ray Examination upon Pregnancy, by Dr. Sinclair Tousey; paper: A Report of Seven Cases of Cesarean Section, by Dr. James D. Voorhees; discussion by Dr. Cragin, Dr. Painter, Dr. Edgar, Dr. Flint, Dr. Marx, Dr. Vineberg, Dr. Stone, and others. Charles F. Adams, M. D., chairman; Arnold Sturmdorf, M. D., secretary, 51 West Seventy-fourth Street.

PHILADELPHIA.

Change of Address.—Dr. C. A. Van Dervoort, to 3311 North Broad Street.

Germantown Hospital Appointments.—Dr. Samuel Bradbury, Dr. Ferdinand Mitchell Perrow, and Dr. Walter E. Kelton, of the University of Pennsylvania, and Dr. H. M. Stewart, of Jefferson Medical College, have been elected resident physicians in the Germantown Hospital.

Arrested for Perjury and Malpractice.—Dr. Oswald Victor Hartmann, of 208 South Twelfth Street, was arrested on April 8th, charged with perjury. On searching his apartments. United States secret service agents found an infant in a satchel. The Federal officers turned the incriminating evidence over to the coroner's office. Hartmann had filed an application with the State Board of Medical Examiners for license to practise medicine; he expected to prove his citizenship by exhibiting a passport, for which he had applied, in which he said he was born in Milwaukee in 1870. The State department found that he was born in Pilsen, Austria, hence the arrest for perjury.

The Health of the City.—The following cases of transmissible diseases were reported to the Bureau of Health for the week ending April 8, 1905:

	Cases.	Deaths.
Typhoid fever.....	161	23
Scarlet fever.....	47	3
Chickenpox.....	61	0
Diphtheria.....	72	16
Cerebrospinal meningitis.....	8	2
Measles.....	43	1
Whooping cough.....	18	5
Tuberculosis of the lungs.....	41	52
Pneumonia.....	63	53
Erysipelas.....	6	0

The total deaths for the week were 503, in an estimated population of 1,438,318; corresponding to an annual death rate of 18.19 a 1,000 population. The total infant mortality was 111; under one year, 89; between one and two years, 22. There were 39 still births; 14 males and 25 females. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 13; puerperal fever, 3; dysentery, 1; diarrhoea and enteritis under two years, 15. The maximum temperature for the week was recorded on the 4th, when the thermometer reached 67°. On April 4th there was a thunderstorm and on the 4th and the 5th 1.26 inches of rain fell.

Medical Legislation.—From time to time during the winter we have noted in these columns the various bills passed by the Pennsylvania legislature, which affect the medical profession and the public health. Now that the legislature has adjourned it may be profitable to review some of this legislation.

State Sanatorium for Tuberculosis.—First, a bill appropriating \$300,000, setting aside parts of the State forestry reservation and appointing a commission of two practising physicians and two commissioners of forestry to select sites and supervise the building of two State institutions for the treatment of persons suffering from incipient tuberculosis, was passed by the legislature and subsequently vetoed by Governor Pennypacker. The veto was made on the ground that if the State should undertake to provide for the treatment of incipient tuberculosis a precedent would be established which would, in time, be used as an argument for State care of other infectious diseases, such as typhoid fever and pneumonia. Furthermore, the governor pointed out that there was no provision in the bill which would confine the benefits of the institution to the poor; but that, as the bill was drawn, the rich would have as much right to free treatment as their unfortunate fellow citizens. When this bill was first proposed an effort was made to have it endorsed by the Philadelphia County Medical Society. The discussion of the resolution offered to accomplish this, which was participated in by some of the leading men in the management of sanatoria for tuberculous patients, developed the fact that there were at present in the State well organized, well equipped, and well managed private institutions for which State aid would be asked, and that if \$300,000 was to be appropriated it might better be appropriated for the improvement and enlargement of these institutions rather than for the be-

ginning of new institutions. At the business meeting of the society in January, however, the society endorsed the plan on recommendation of a committee, which investigated it. After the governor's veto of the bill newspaper editorials and an address by the president of the Pennsylvania Society for the Prevention of Tuberculosis took the executive to task in a somewhat severe way. It appears to us that the veto of the bill was for the best interests of the men who have the interests of the tuberculous poor at heart, and that they should devote their energies to securing large appropriations for charitable institutions already started and efficiently managed. The legislature has appropriated \$100,000 to the White Haven Sanatorium, one of this class of institutions. The appropriation is not large enough, and it is hoped that the governor will not reduce it.

The State Department of Health.—A second piece of legislation of great importance is the passage of a bill establishing a State department of health. The bill creates a commissioner of health, who must be a physician of ten years' practical experience, who shall be appointed by the governor and who shall receive a salary of \$10,000 per annum. An advisory board of six members is to be appointed, the majority of which must be physicians. The powers of the commissioner of health are large, and if the first commissioner is a man who has good judgment and who cannot be tampered with, much good may be expected of the new department. The State, according to the provisions of the bill, is to be divided into ten districts, each to be in charge of a physician of at least five years' experience, who shall receive a salary of \$2,500 per annum. Fines and imprisonment are provided as penalties for those who violate the orders or the regulations of this department. Two other bills which passed the legislature at about the same time and which have a bearing on the State department of health provide for the establishment of a State bureau of vital statistics and for the preservation of the purity of the waters used for drinking purposes.

The Osteopathic Bill.—The bill to regulate the practice of osteopathy and licensing osteopaths in Pennsylvania has had a rough passage. At first the legislature failed to pass it. Next, it was reconsidered; the newspapers said because the member who had the bill in charge had done good work for the "organization," and as he was interested in the bill, it was allowed to be reconsidered and passed as a reward of merit. The bill is now on the governor's desk. At the meeting of the Philadelphia County Medical Society on Wednesday evening, April 12th, a committee, composed of Dr. L. Webster Fox, Dr. J. Madison Taylor, Dr. Hobart A. Hare, Dr. Alfred Stenzel, Dr. Henry Beates, Jr., and Dr. Charles H. Frazier, was appointed to place before the governor the reasons why the bill should not become a law.

Food Adulteration.—The legislature passed a bill regulating the manufacture and sale of fruit syrups for use in soda waters, etc. The bill provides that any person found selling fruit syrups

which contain formaldehyde, sulphurous acid, or sulphites, boric acid or borates, salicylic acid or salicylates, saccharin, dulcin, glucin, betanaphthol, abristol, asaprol, fluorides, fluorborates, fluorsilicates, or other fluorine compounds, also all coal tar dyes, copper sulphate, and all other coloring matter injurious to health, shall be deemed guilty of a misdemeanor. It also provides for a fine of from \$60 to \$100, with costs, or imprisonment not exceeding sixty days, or both, at the discretion of the court. The great criticism, it seems to us, with food legislation at present is that most of it is hasty and ill advised. We do not mean to pass judgment on this bill, but if it belongs to the class that District Attorney Jerome calls "moral yearning laws," the governor can afford to veto it.

Health of Domestic Animals and Care of Indigent Insane.—The governor has signed a bill to amend the fourth section of the act to protect the health of the domestic animals of the State by providing penalties and methods of procedure for the enforcement of the provisions of the act. He has also signed a bill appropriating \$2,000,000 for the care of the indigent insane for the next two years, and fifty cents a week in addition for each person cared for.

The Fifth Annual Dinner of the Northern Medical Association was held at Mosebach's Restaurant, 1463 North Broad Street, on Tuesday evening, April 11th. Covers were laid for seventy-five members and guests. Toasts were responded to by Dr. Albert Bernheim, the president of the society, Dr. William B. Atkinson, Dr. Solomon Solis-Cohen, Dr. Henry Beates, Dr. B. L. Singer, and Dr. John W. Millick. Dr. Thomas Shriner acted as toastmaster. The Northern Medical Association is the oldest medical organization in Philadelphia, except the College of Physicians. It was organized fifty-nine years ago, one year before the Philadelphia County Medical Society. Its scientific meetings are held throughout the winter months on the second and fourth Friday evenings, at Sixth Street and Fairmount Avenue.

Social Affairs for Charitable Objects.—A "measuring tea" for the benefit of the Seaside Home at Cape May Point was given in Witherspoon Hall on April 20th by Mrs. Elias Naudain.

Mr. George Kiernan, of Pittsburgh, presented *Rip Van Winkle* at the New Century Drawing Room on April 10th for the benefit of the Woman's College Hospital.

An international fair will be held at the residence of Mr. and Mrs. John Wanamaker, at Jenkintown, on May 24th, for the benefit of the Jefferson Maternity.

Meetings of Scientific Societies for the Week Ending April 29, 1905.—Monday, April 24th, Mineralogical and Geological Section, Academy of Natural Sciences; Section in Medical History, College of Physicians. Tuesday, April 25th, Medicolegal Society; Northwest Medical Society; Philadelphia Neurological Society. Wednesday, April 26th, Philadelphia County Medical Society. Thursday, April 27th, Pathological Society; Entomological Section, Academy of Natural Sciences.

Friday, April 28th, South Branch, Philadelphia County Medical Society; Northern Medical Association.

Officers of the Pennsylvania Society for the Prevention of Tuberculosis were elected at the annual meeting held on April 12th. They are:

President, Dr. Joseph Walsh; vice-presidents, Dr. M. P. Ravenel, Dr. Benjamin Lee, Dr. Talcott Williams, Dr. A. B. Craig, Dr. Howard S. Anders, Samuel Castner, Dr. Samuel G. Dixon, Dr. Lawrence F. Flick, Samuel Scoville, Jr., Dr. Seneca Egbert; secretary, Dr. Ward Brinton; solicitor, James L. Stanton; treasurer, the Commonwealth Title Insurance and Trust Company; board of directors, Dr. Flick, Dr. G. W. Norris, Dr. D. J. McCarthy, Dr. Anders, Dr. Leonard Pearson, James L. Stanton, W. B. Stanton, Dr. J. W. Irwin, Dr. A. E. Roussel, Dr. Ravenel, Dr. A. H. Davidson, Dr. J. Solis-Cohen, Dr. Walsh, Dr. Brinton, Samuel Scoville, Jr.

The Annual Meeting of the American Philosophical Society was held in Philadelphia on April 12th, 13th, and 14th. Among the papers of interest to physicians which were read were A Plea for Governmental Supervision of Posts Necessitating Normal Perception of Color, by Dr. Charles A. Oliver, of Philadelphia; The Oligodynamic Action of Copper on Some Intestinal Organisms, by Dr. Henry Kraemer, of Philadelphia; The Effects Upon Metabolism of Preservatives Added to Food, by Dr. H. W. Wiley, of Washington; Reason and Intelligence *vs.* Custom and Habit in the Nutrition of the Body, by Dr. Russell N. Chittenden, of Yale University. A reception by the president and council of the society was given at the Free Museum of Science and Art on Thursday evening, April 13th, at 9 o'clock. The annual dinner was given at the Bellevue-Stratford Hotel on the evening of the 14th.

GENERAL.

Richmond, Va., Academy of Medicine and Surgery.—The subject for discussion at this academy on April 25th is Eczema, and Dr. F. H. Beadles and Dr. Thomas W. Murrell will participate.

Personal.—Dr. Jesse C. Coggins has resigned as assistant physician at the Maryland Hospital for the Insane at Catonsville, after having been associated with the institution for nine years. He will enter private institutional work.

Governor McDonald has appointed Dr. S. D. Van Meter, president of the Colorado State Board of Health, as a delegate to represent Colorado at the council on medical education of the American Medical Association, which will be held in Chicago, April 20th.

The Sullivan County, N. Y., Medical Association elected the following officers on April 12th: President, Dr. H. P. Deady, of Liberty; vice-president, Dr. S. W. Wells, of Liberty; secretary, Dr. Frank Laidlaw; treasurer, Dr. C. S. Payne.

Chicago Neurological Society.—The next meeting of the Chicago Neurological Society will be held at the Sherman House, Thursday, April 29th, at 6.30 p. m. Dr. Hugh T. Patrick will present a case for diagnosis. Dr. Alfred C. Croftan will relate some studies upon Epilepsy of Gastrointestinal Origin. Dr. J. H. Hess will show some specimens of Sarcoma of the Brain. L. Harrison Mettler, secretary and treasurer, 100 State Street.

The Hornellsville, N. Y., Medical and Surgical Association, at its meeting and banquet on April 4th, elected officers as follows: President, Dr. J. G. Kelly; vice-president, Dr. C. S. Parkhill; secretary-treasurer, Dr. Leon M. Kysor.

McGill Medical Society, Montreal.—The following officers have been elected by this society for the coming year: President, Mr. H. H. Christie; honorary president, Dr. George E. Armstrong; vice-president, C. E. Walsh; secretary, J. Healy; treasurer, O. E. Rublee.

Statement of Mortality in Chicago for the Week Ending April 15, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	April 15, 1905.	April 8, 1905.	April 16, 1904.
Total deaths, all causes.....	548	512	616
Annual death rate per 1,000.....	14.35	13.40	16.66
By sexes.....			
Males.....	305	304	359
Females.....	243	208	257

All other causes.....	102	113	129

American Proctological Society.—The seventh annual meeting of this society will be held at Pittsburgh, Pa., May 5 and 6, 1905, at the Hotel Henry. The following papers will be read:

Annual address of the president, by Dr. J. R. Pennington, of Chicago; papers: Malignant Disease of the Rectum and Its Treatment, by Dr. G. B. Evans, of Dayton; The Ambulant Treatment of Internal Hemorrhoids, by Dr. C. F. Martin, of Philadelphia; Instrumental Massage in the Treatment of Acquired Valvular Hypertrophy (Obstipation), by Dr. T. C. Martin, of Cleveland; A Report of Cases, by Dr. Leon Straus, of St. Louis; Urethrorectal Fistula, with Report of a Case, by Dr. W. M. Beach, of Pittsburgh; Tuberculous Fistulas of the Rectum, and the Repair of Extensive Injuries of the Bowel Following Same, by Dr. Howard A. Kelly, of Baltimore; The Operative Treatment of Tuberculous Fistulas in Tuberculous Subjects, with Report of a Case, by Dr. J. Coles Brick, of Philadelphia; Formalin in the Treatment of Diseases of the Rectum, Sigmoid, and Colon, by Dr. John L. Jelks, of Memphis; A Further Contribution to the Study of Pruritus Ani, with Special Reference to Local Treatment, by Dr. Lewis H. Adler, Jr., of Philadelphia; Profound Secondary Anæmia Due to Rectal Diseases: Report of Six Cases, by Dr. D. H. Murray, of Syracuse; Personal Experience in the Employment of Mechanical Vibration in the Treatment of Rectal Diseases, by Dr. William L. Dickinson, of Saginaw; The Office Treatment of Rectal Diseases and Its Limitations, by Dr. James P. Tuttle, of New York; Two Cases of Imperforate Anus, by Dr. T. L. Hazzard, of Pittsburgh; Amoebic Dysentery: Report of Recent Investigations in Its Treatment, by Dr. Samuel T. Earle, of Baltimore; Artificial Anus: Practical Suggestions Regarding Its Making and Closing, by Dr. S. G. Gant, of New York; The Pathology of External Hemorrhoids, by Dr. Louis J. Krouse, of Cincinnati; The Treatment of Rectal Prolapse, by Dr. A.

Tierlinck, of Ghent, Belgium; A Summary of Twenty Radical Operations Upon the Rectum Under Local (Sterile Water) Anesthesia, by Dr. A. B. Cooke, of Nashville.

Meeting of the Michigan State Board of Health at Lansing, April 14, 1905.—The regular meeting of the State Board of Health was held in the secretary's office, Lansing, April 14, 1905. The members present were: Dr. Victor C. Vaughan, president, Honorable Henry A. Haigh, Charles M. Ranger, Honorable Coleman C. Vaughan, Dr. Angus McLean, Dr. Malcolm C. Sinclair, and Dr. Frank W. Shumway, secretary.

After auditing of bills and the disposal of other routine work, Dr. Vaughan, the president, addressed the board briefly and suggested certain lines of work that might properly be considered by the board. He urged the advisability of the board putting forth every possible effort to secure legislation providing for a State Sanatorium for Consumptives, and in this connection Dr. Vaughan also mentioned the importance of collecting reliable statistics on the geographical and class distribution of the disease which would be of great assistance in ascertaining important facts on the prevalence of consumption. Such statistics would also enable the board to work intelligently for the restriction of this disease and in securing legislation providing for a State sanatorium. Many of the States had such institutions, notably among those mentioned being Massachusetts, New York, Pennsylvania, Ohio, and New Jersey, while many other States had bills before their legislatures providing for similar institutions. Dr. Vaughan suggested that a feature of the work of the board for the next two years be the special study of tuberculosis, and to ascertain if the prevalence of this disease in Michigan was increasing or decreasing. The work of the board for the restriction and prevention of pneumonia was considered of great importance, and should be continued as deaths from this disease were rapidly increasing, and its cause and means of spread were problems that the board might properly consider. Dr. Vaughan also mentioned the important line of work carried on through the distribution of the teachers' sanitary bulletins and the good results that had been accomplished through this work. The board arranged the details for holding the annual conference of health officials, June 1st to 2nd, at the State Laboratory of Hygiene at Ann Arbor. The president and secretary were appointed a committee to arrange a programme for this conference, and the secretary was instructed to send announcement and programme of this meeting to every local health officer in the State and others interested in public health work in an endeavor to have an enthusiastic and profitable meeting. Dr. Sinclair, being a special committee appointed by the board at a meeting on April 8th to examine the alleged pollution of the water supply of the city of Grand Rapids through sewage from the soldiers' home being emptied into Grand River, made a verbal report to the board on the subject and presented resolutions adopted by the local board of health of the city of Grand Rapids, in which it was stated that it had taken proper steps, as advised by the State board of health, to abate the conditions leading to the contamination of the water supply of the city of Grand Rapids. Dr. Sinclair's report was accepted. This meeting being the annual meeting of the board Dr. Vaughan, who had been elected as president at the regular meeting of the board, January 20th, to fill the vacancy caused by the death of Honorable Frank Wells, was unanimously reelected president for the ensuing two years.

Mortality of Michigan During March, 1905.—There were 3,367 deaths returned to the secretary of State for the month of March; an increase of 149 over the preceding month. The death rate was 15.5 a 1,000 population as compared with 16.4 for February and 16.0 for March, 1904. By ages there were 687 deaths of infants under one year, 194 deaths of children one to four years, and 1,070 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis of lungs, 227; other forms of tuberculosis, 46; typhoid fever, 31; diphtheria and croup, 26;

scarlet fever, 10; measles, 16; whooping cough, 5; pneumonia, 399; diarrhoeal diseases of infants under two years, 58; meningitis, 54; influenza, 150; cancer, 158; accidents and violence, 150. There was some increase in the number of deaths reported from tuberculosis and cancer, and a decrease from typhoid fever and pneumonia. Meningitis showed about the same mortality as in February. No epidemic prevalence was reported from any part of the State. Three deaths from smallpox occurred, as follows: One in Alpena city, Alpena county; one in Jackson city, Jackson county, and one in Perry village, Shiawassee county.

An Appeal for the Canadian Brehmer Rest.—

The philanthropic idea of establishing a recuperative home in the mountains, near Montreal, Can., for patients suffering from anæmia or debility, and for those unfortunately predisposed to pulmonary weakness has been suggested by a number of Canadian women interested in the duty of preventing tuberculosis, who have volunteered to direct and supervise this worthy undertaking, and have promised to collect the amount sufficient to meet half the annual cost of running the institution for the first year, which they hope to manage in a way as to make it self supporting. In addition to the amount required annually for carrying on the good work, there is immediate need of \$500 to equip the home with bare necessities, and in addition to this sum \$1,100 will be required, and if immediately available the home will be opened on May 15, 1905. The Brehmer Rest will be non-sectarian, and both men and women will be received, each on payment of \$4.00 a week. The Brehmer Rest is situated two miles from Ste-Agathe, near Montreal. Particular attention will be devoted to imparting instruction to patients in hygienic living, and each will on recovering health possess sufficient knowledge to be sent out to preach the gospel of tuberculosis prevention. A special committee will have charge of the institution and will provide worthy indigents with all transportation facilities. Contributions have been received from many persons, showing their appreciation of such a want nearer Montreal, as it solves the difficulty so often to be faced, viz.: the sending away to Muskoka, Colorado, etc., of indigent invalids. Further information can be obtained from any member of the committee: President, Mrs. Annie Wheeler; first vice-president, Mrs. R. M. Liddell; treasurer, Mrs. C. W. Lindsay; secretary, Miss Barnard.

Medical and Chirurgical Faculty of Maryland.

—The tenth annual meeting will be held at Baltimore, April 25, 26, and 27, 1905, when the following papers will be read:

Malignant Disease Developing in, or Accompanying Uterine Myomata, by Dr. T. S. Cullen; Review of the Deaths Due to Cancer During the Past Fourteen Years, by Dr. C. Hampson Jones; A Severe Case of Tetanus Successfully Treated with Antitoxine, by Dr. Charles F. Davidson; Some Remarks on the Recent Diet Cures in the Treatment of Diabetes, by Dr. Julius Friedenwald and Dr. John Ruhrah; Empyema of Frontal Sinus. (Exhibition of Patient), by Dr. R. H. Johnston; Gastric Conditions in Urticaria, by Dr. L. K. Hirschberg; The Physiological Basis and Clinical Effects of Hydrotherapy in Chronic Disorders, by Dr. Simon Baruch; Collaboration in Medical Education, by

Dr. Clarence J. Blake, professor of Otology, Harvard University; A Consideration of the Benefits Conferred Upon Humanity by Medical Science: a. Preventive Medicine, by Dr. William H. Welch; b. Modern Therapeutics, by Dr. I. E. Atkinson; c. The Debt this Generation Owes to Surgery, by Dr. Robert W. Johnson; "Symposium" on the Newer Methods of Clinical Investigation: a. Improved Chemical Methods in the Clinical Laboratory, by Dr. E. L. Whitney; b. Blood Pressure Observations for the Practising Physician, by Dr. Clinton E. Brush; c. Leucocytosis, by Dr. Thomas B. Farrar; d. Cytodiagnosis in Psychiatry, by Dr. Clarence B. Farrar; The Success Which at the Present Day Attends the Operation of Cataract Extraction and the Causes Which Contribute to it, by Dr. Samuel Theobald.

Annual oration: Unity, Peace, and Concord, by Dr. William Osler. The meeting will close after the presentation of a portrait of Dr. William Osler to the Medical and Chirurgical Faculty by his medical friends; presentation address by Dr. George J. Preston.

The National Association for the Study and Prevention of Tuberculosis.—The plans for the annual meeting of this association to be held in Washington, May 18 and 19, 1905, under the presidency of Dr. Edward L. Trudeau, are now rapidly approaching completion. At the general meeting of the association to be held on the morning of the 18th, addresses will be made by the president and by the two vice-presidents, Dr. William Osler, of Baltimore, and Dr. Hermann M. Biggs, of New York. The afternoon of the 18th and the morning and afternoon of the 19th will be given up to meetings of the sections, of which there are three:

Sociological—Homer Folks, New York, chairman; Miss Lilian Brandt, New York, secretary.

Clinical and Climatological—Dr. Norman Bridge, Los Angeles, chairman; Dr. Sherman G. Bonney, Denver, secretary.

Pathological and Bacteriological—Dr. M. P. Ravenel, Philadelphia, chairman; Dr. D. J. McCarthy, Philadelphia, secretary.

The sociological section in addition to the report by the chairman will offer papers on A Working Programme for Associations for the Prevention of Tuberculosis, National, State, and Local, by Edward T. Devine, of New York; Progress of the Sanatorium Movement in America, by William H. Baldwin, of Washington; and Infection in Transportation, by Dr. H. M. Bracken, of St. Paul. The climatological and clinical programme in addition to the address of the chairman includes a number of reports and papers of particular significance. The report of the committee on clinical nomenclature under the chairmanship of Dr. Vincent Y. Bowditch, of Boston, will be discussed by Dr. Welch, Dr. Trudeau, Dr. Stengel, and Dr. Vaughan. From a practical point of view there is probably no subject upon which agreement is more necessary than this and an authoritative pronouncement by a body of the authority of the national association is greatly to be wished. The report of the committee on early diagnosis, under the chairmanship of Dr. Arnold C. Klebs, of Chicago, will be discussed by Dr. Osler, Dr. Janeway, Dr. Knight, and Dr. Babcock. The role of climate in the management of tuberculosis is also the subject of a committee report by Dr. C. L. Minor, of Asheville, the chairman. A "symposium" on the sanatorium treat-

ment of consumption also promises matter of interest. Other papers are expected by Dr. C. L. Greene, of St. Paul; Dr. William S. Halstead, of Baltimore; Dr. C. F. Gardner, of Colorado Springs; Dr. Edward O. Otis, of Boston; Dr. S. A. Knopf, of New York; Dr. J. A. Wilder, of Denver; Dr. H. B. Loomis, of New York; and Dr. William Porter, of St. Louis. The pathological and bacteriological section will, naturally, be strictly technical in scope. An introductory address will be made by Dr. William H. Welch on Channels of Infection in Tuberculosis, which will be of general interest and value. The final programme of the meeting will be complete in the course of a week. Invitations have been sent to the various antituberculosis organizations in the United States to be represented by delegates at this meeting and a large attendance is expected. The printed papers resulting from a gathering of such authority as this should afford invaluable material in the campaign of education which is now being pushed throughout the country.

American Antituberculosis League.—The programme for the opening exercises for this league held at Atlanta, Ga., April 17 to 19, 1905, was as follows:

The Cause and Prevention of Tuberculosis in the Negro—Considered Largely from a Sociological Standpoint, by Dr. Seale Harris, of Union Springs, Ala.; Some Sociological Considerations for the Antituberculosis Crusade, by Dr. Marion G. Chancey, of Key West, Fla.; The Natural Way of Preventing Tuberculosis in Southern Latitudes, by Dr. J. C. LeHardy, of Savannah, Ga.; Prophylaxis Should Begin Before Conception. After Birth it Naturally Divides Into Two Branches, the Preservation or Development of Immunity and the Prevention of Infection, by Dr. W. S. Alexander, of Oxford, O.; The Treatment and Management of Tuberculosis Patients with Special Reference to Prevention, by Dr. F. F. Young, of Abbeville, La.; State Control of Tuberculosis Disease, by Dr. R. E. Conniff, of Sioux City, Iowa; A Plea for State in the Combat of Tuberculosis, by Dr. H. B. Weaver, of Asheville, N. C.; Tuberculosis in the State Institutions in Tennessee, by Dr. W. J. McMurray, of Nashville, Tenn.; How Shall We Secure the Cooperation of Our Tuberculosis Patients in the Early Stage of Their Disease? A Plea for Legislation, by Dr. Sheridan Waters, of Brookport, Ill.; Some Ways to Prevent the Spreading of Tuberculosis, by Dr. Thomas A. Jones, of Ridgeway, Ill.; The Crusade Against Tuberculosis, by Dr. Charles A. Julian, of Thomasville, N. C.; How Can Conditions Chiefly Responsible for the Spread of Tuberculosis be Overcome, by Dr. J. M. Masters, of Newport, Tenn.; Ten Years of Tuberculosis in Richmond, Va. Some Lessons from Official Sources, by Dr. Ramon D. Garcin, of Richmond, Va.; What Can and Will Be Done in the Future for the Prevention of Tuberculosis, by Dr. C. C. Curtis, of Lower Peachtree, Ala.; Can Tuberculosis Be Eradicated? by Dr. C. Barlow, of Robinson, Ill.; Sanitation and Isolation, Two Requisite Factors in the Eradication of Tubercle Bacilli, by Dr. W. H. Vail, of St. Louis, Mo.; Reports from Some Tuberculosis Sanatoria, by Dr. Thomas Franklin Smith, of New York city; The Best Means to Stamp Out Consumption, by Dr. R. F. Hanesberger, of Beckville, Texas; The Necessity for Cooperative Clinical Research in Testing the Merits of the Various Proposed Methods of Treatment of Tuberculosis, by Dr. Frank C. Wilson, of Louisville, Ky.; The Rational Use of Rest in the Treatment of the Fever of Phthisis, by Dr. J. F. McConnell, of Colorado Springs, Colo.; Bacteriological Diagnosis of Pulmonary Tuberculosis, by Dr. F. W. Abbott, of Taunton, Mass.; We See Through a Glass Darkly, but We See Something, by Dr. R. J. Price, of Vienna, Md.; Educational Influence and Significance of Sanatoriums for Cases of Incipient Tuberculosis, by Dr. George Homan, of St. Louis, Mo.; Duty of State and the Medical Profession to Consumptives, by Dr. C. W. Fry, of Huntington, Ind.; The

Use of Phenol in the Care and Treatment of Tuberculous Patients, by Dr. Charles M. Watson, of Florence, Ala.; Tuberculous Insomnia, by Dr. J. B. Larned, of Northampton, Mass.; On the Parasitic Origin of Phthisis Pulmonalis or Consumption of the Lungs, by Dr. C. H. Tebault, of New Orleans, La.; A Further Report of Results from the Use of Endotracheal Infection in the Treatment of Tuberculosis, by Dr. W. W. Mangum, of Eufaula, Ala.; Sanitary Treatment of Consumption, by Dr. W. S. Pryor, of Chester, S. C.; The Direct Treatment of Pulmonary Tuberculosis, by Dr. John L. Sweeney, of Chicago, Ill.; Aetiology and Treatment of Tuberculosis, by Dr. John C. McCandless, of Chicago, Ill.; Local Treatment of Tuberculosis of the Upper Air Passages, by Dr. J. H. Hallock, of Saranac Lake, N. Y.; Some Methods of Treatment of Tuberculosis, by Dr. A. C. Foster, of Morganfield, Ky.; Cataphoretic Treatment of Tuberculosis in Connection with Ordinary Drug Medication, by Dr. M. Beshoar, of Trinidad, Colo.; The Climate of Florida in Tuberculosis, by Dr. Henry R. Stout, of Jacksonville, Fla.; The Röntgen Light in the Early Diagnosis and Treatment of Tuberculosis, by Dr. J. Rudis-Jicinsky, of Cedar Rapids, Iowa; The Three Most Important Factors in the Treatment of Tuberculosis, by Dr. R. E. Bledsoe, of Somerville, Texas; The Importance of Climate in the Treatment of Tuberculosis, by Dr. Charles J. Lavery, of Fort Pierre, S. D.; The Cottage Treatment of Phthisis in Florida, by Dr. J. D. Bennett, of Crystal River, Fla.; Treatment of Pulmonary Diseases by Inhalation, by Dr. F. S. Twitty, of Columbia, Ala.; Home Care and Treatment of Tuberculosis, by Dr. S. B. Flynt, of Meridian, Miss.; Some Clinical Experiences in the Treatment and Prevention of Tuberculosis, by Dr. Augustus P. Clarke, of Boston, Mass.; My Personal Observation and Experience in the Aetiology and Pathology of Tuberculosis, by Dr. L. Montgomery, of Micanopy, Fla.; Diagnosis of Tuberculosis and Some Lung Diseases, by Dr. A. A. McKitterick, of Evergreen, Ala.; The Physician's Permanent Duty to the Patient and Family in Tuberculosis, by Dr. C. P. Ambler, of Asheville, N. C.; The Tuberculosis Woman in Colorado, by Dr. Mary Hawes, of Denver, Colo.; Our Family Physician, by Dr. Olivia Nelson, of Paducah, Ky.; Heredity a Factor in Tuberculosis, by Dr. G. J. Ross, of Sioux City, Iowa; What Influence, if Any, Does Heredity Have in the Development of Tuberculosis, by Dr. John H. Jamar, of Elkton, Md.; The Mind in Tuberculosis, by Dr. M. A. Brawley, of Frankfort, Ky.; Hereditary Transmission of Tuberculosis, by Dr. C. O. Robinson, of Blair, Neb.; Practical Antituberculosis, by Dr. T. N. Gray, of East Orange, N. J.; Our Public Schools as a Possible Antituberculosis Doctor, by Dr. J. H. Neff, of Harrisonburg, Va.; One or More Ways to Eradicate Tuberculosis, by Dr. John P. Blankenship, of Maryville, Tenn.; The Diagnosis of Early Consumption, by Dr. Hazle Padgett, of Columbia, Tenn.; The Histology of the Tubercle, by Dr. C. H. Anderson, of McLeansville, Ill.; Effect of Malaria on Tuberculosis, by Dr. Samuel A. Southal, of Lonoke, Ark.; What Advice Should Be Given Relative to the Employment of Tuberculosis Subjects in Cotton Mills, by Dr. J. H. Hammond, of LaFayette, Ga.; Out Door Life a Prevention, by Dr. J. G. Brooks, of Paducah, Ky.; Tuberculous Peritonitis in Women, by Dr. Henry O. Marcy, A. M., M. D., LL. D., of Boston, Mass.; Considerations on the True Causes of Tuberculosis, and Its Treatment by Physiotherapy, by Dr. J. A. Révière, of Paris, France; (A) Phymol, a Memoir on the Treatment of Pulmonary Consumption with a New Drug, Its Composition, Its Therapeutic Value, Its Indication, Its Mode of Employment, by Dr. William Guillemin Livet, of the Faculty of Paris; (B) Notes on Bacillosine, as a Remedy Against Tuberculosis; Primary Tuberculosis in the Rectum, by Dr. William M. Beach, of Pittsburgh, Pa.; Skiagraphy of the Tuberculosis Chest, by Dr. Preston M. Hickey, of Detroit, Mich.; Contagiousness of Tuberculosis, by Dr. F. P. Hoover, of Jacksonville, Fla.; Tuberculosis in the Negro, by Dr. E. H. Jones, of Murfreesboro, Tenn.; Tuberculosis in the Negro, Its Causes and Treatment, by Dr. John E. Hunter, of Lexington, Ky.; Prevailing Ideas Upon Open Air Treatment of Tuberculosis and Some of Their Fallacies, by Dr. Henry H. Stone, of Phenix, Ariz.; The Rapid Increase of Tuberculosis in the South, by Dr. R. H. Tatum, of Chattanooga, Tenn.; Visit to New Mexico, by Dr. G. Huston Chapman, of Uniontown, Ky.; The Active Allies of Tuberculosis, by Dr. V. L. Lockhart, of Maysville, Ga.; Isolation of Tuberculous Subjects, by Dr. Frank Cordele, of Trion, Ga.

Pith of Current Literature

LYON MEDICAL.

March 19, 1905.

1. The Biological Value of the Azoturic Coefficient,
By E. DUFOUT.
2. Nephrectomy in Renal Tuberculosis,
By RAFIN.

1. **Biological Value of the Azoturic Coefficient.** Dufourt claims that the azoturic coefficient should not be considered as measuring the oxidation in the organism, nor the utilization of albuminoid material, but wholly as related to the antitoxic function of the liver.

2. **Nephrectomy in Renal Tuberculosis.**—Rafin presents the histories of twenty primary nephrectomies. The patients varied in age between 19 and 48 years; 13 were women, 7 men; 9 had had the right kidney removed, 11 the left. The writer considers at some length the other tuberculous lesions present, the manner of attack, the conditions of the bladder at the time of operation, the subjective and objective symptoms presented by the kidneys and the methods of determining whether the lesion is unilateral or bilateral, with the functional value of each kidney. The methods of examination dealt with are palpation, rectal or vaginal, cystoscopy, ureteral catheterization, and intravesical separation.

March 26, 1905.

1. The Part Played by Compression of the Portal Vein in Certain Serious Accidents After Operations on the Transverse Fissure of the Liver,
By EUGENE VILLARD.
2. Nephrectomy in Renal Tuberculosis (Concluded),
By RAFIN.

1. **Compression of the Portal Vein.**—Villard reports three cases and concludes (1), that it is possible to compress accidentally the portal vein by means of a gauze tampon placed in the subhepatic region; (2) that this compression can give rise to formidable and rapidly mortal accidents which simulate internal hemorrhage; (3) that in practice one should avoid placing gauze drainage too tightly in the subhepatic region or so as to cause compression, and that when such an accident threatens, the causes of compression should be lessened after assurance has been obtained that a true hemorrhage is not occurring.

2. **Nephrectomy.**—In this number Rafin continues the discussion of the technics of the operation, the operative accidents, the mortality, and the final results. The mortality is given as three out of twenty, or 15 per cent. The general health as well as the local condition of the urine and bladder were improved in the patients who survived the operation.

PRESSE MEDICALE

1. Vernix Caseosa. Hereditary Seborrhœa and Fœtal Acne,
By JACQUET and RONDEAU.
2. Tabetic Optic Atrophy,
By F. TERRIEN.

1. **Vernix Caseosa.**—Jacquet and Rondeau state that they found the vernix caseosa well

marked in forty-one per cent. of 287 infants, slight in thirty-four per cent., and absent in seventeen per cent. Histologically it consists of three principal elements: 1, A great many cells, mostly of the epidermic type, globular and clear, rather frequently nucleated; 2, Free fat, the presence of which is shown by the action of osmic acid which colors it dark brown or black; 3, A fairly large number of lanugo hairs. The vernix testified to a remarkable activity of the pilosebaceous apparatus in the fœtus. Another form of activity of the same apparatus results in the production of a milary sebaceous acne, which is present on many infants at birth. The question of heredity as affecting the seborrhœal condition is discussed and some points are advanced which favor the idea that at least heredity may cause an increased tendency toward seborrhœa, but the writers hardly prove that seborrhœa of the infant may be called properly a hereditary disease. Indeed, they rather seem to lend themselves to the theory that the relation between the activity of the seborrhœal glands and the sexual is the same in the fœtus as in the adult, and that the cause of milary seborrhœa and of fœtal acne is the evolution of the genital organs.

2. **Tabetic Optic Atrophy.**—Terrien thinks that about thirty-four per cent. of tabetic patients have atrophy of the optic nerve. This percentage seems rather high, as some observers have placed it as low as fifteen per cent. The atrophy may appear at any stage of the disease. Ophthalmoscopically two pictures are presented; hyperæmia of the papilla with neuroretinitis, and simple optic atrophy. The seat of the lesion is essentially peripheral. The modifications of the visual field are variable, but may be grouped into three classes: those of concentric contraction, contraction of a sector, and total diminution. The latter is the more frequent. Central vision is maintained for a long time; color vision is impaired. Exceptionally there is a central scotoma, while the rest of the visual field remains normal. The sense of light is usually little changed and hemeralopia is exceptional. Prognosis is unfavorable.

March 25, 1905.

1. The Centenary of Manuel Garcia, Inventor of the Laryngoscope,
By MARCEL LERMOYEZ.
2. Acute Rheumatic Arteritis,
By ERNEST BARIÉ.

1. **Centenary of Manuel Garcia.**—Lermoyez presents a eulogy on the occasion of the hundredth birthday of Manuel Garcia, who published his discovery of the laryngoscope in 1855. The article is illustrated by reproductions of two photographs, one of Garcia at the age when he discovered the laryngoscope, the other at the present time.

2. **Acute Rheumatic Arteritis.**—Barié reports a case in which there was a rise of temperature with slight pain in the scapulohumeral articulation on the fifteenth day of an attack of acute articular rheumatism. The movements of the elbow joint were not painful, but about a centimetre and a half above the fold of the elbow was an energetic pulsation of the skin caused by the intense

beating of the brachial artery, which felt less yielding between the fingers than the artery on the opposite side. Slight pressure on the vessel caused severe pain. Under the influence of quiet and salicylates the intense throbbing of the artery diminished. On the seventh day of the arteritis the radial pulse was weak and the patient complained of a tingling sensation in the fingers. The heart sounds were normal. During the six following days there was little change except that the beating of the artery slowly approached normal. The patient then became convalescent and recovered sixteen days after the onset of the arteritis.

1. The Frequency of Angina from Spirillæ and Fusiform Bacilli, By H. VINCENT.
2. The Sanitary Inspection of Schools. Participation of the Fathers of Families in this Inspection, By H. SURMONT.

1. Angina from Spirillæ and Fusiform Bacilli.

—Vincent, on account of what has been published on this subject, made a study of 221 cases of angina at the Hôpital Val-de-Grace, and obtained the following results:

	Cases.	Per cent.
Diphtheritic angina, simple or complicated.	13	5.88
Angina from spirillæ and fusiform bacilli.	5	2.26
Angina from streptococci.	95	42.98
Angina from staphylococci.	57	25.79
Angina from pneumococci.	9	4.07
Angina from coli bacilli.	2	0.90
Angina from Friedlander's bacilli.	1	0.45
Polymicrobial angina, or indeterminate.	39	17.64

2. Sanitary Inspection of Schools.—Surmont

urges a reorganization of the sanitary inspection of the French schools, and proposes that the heads of families take part therein.

Pathogeny and Clinical Varieties of Mitral Stenosis,

By ERNEST BARIÉ.

Mitral Stenosis.—Barié says that in general terms organic heart disease is caused by one of two factors, infection and intoxication. Under infections are classed acute articular rheumatism, eruptive fevers, and infectious diseases, such as typhoid fever, gonorrhœa, syphilis, and erysipelas. Under intoxication are classed certain poisons, such as lead and alcohol, and certain dyscrasias, like gout. The first variety mentioned is mitral stenosis dependent on an acute endocarditis of rheumatic origin. According to Sir Dyce Duckworth this includes sixty per cent. of all cases. A second variety is characterized by the association of the mitral stenosis with arteriosclerosis, a combination which renders the prognosis bad. The third variety is one of pure mitral stenosis, first described by Duroziez in 1877. This variety forms the real subject of the paper. The lesion seems to develop without any demonstration, and has been met with in infancy. The primary cause has not yet been demonstrated, and it is met with more frequently in women than in men. The author considers the theories of intrauterine infection, foetal endocarditis, and cardiac hyperplasia insufficient, although he favors the idea that the

lesion is of congenital origin. He points out that heredity plays an incontestable part in its production, and that the two infections which almost always accompany hereditary dystrophy are tuberculosis and syphilis. Yet he seems to incline to the view that the stenosis of the valve is a malformation due to an arrest of embryonal development.

March 20, 1905.

The Identity of the "Fourth Disease" with Scarlatina Variegata, By L. CHEINISSE.

The "Fourth Disease" and Scarlatina Variegata.—Cheinisse uses for a text an article published in the *Lancet*, July 14, 1900, by C. Dukes on the Confusion of Two Different Diseases Under the Name of Rubella (Rose Rash). This writer apparently referred somewhere in that article to the "fourth disease," perhaps as understood by some writers, including M. Cheinisse, descriptive of a new eruptive disease. At any rate the present writer analyzes the description given, and decides that the disease in question is identical with *la rubéole scarlatineuse* or scarlatina variegata.

ZENTRALBLATT FUER GYNAEKOLOGIE.

March 4, 1905.

1. Lutein Cell Development in Atresic Follicles, By L. SEITZ.
2. Uterine Rupture, By A. VON VALENTA.

1. Lutein Cells.—Seitz draws attention to the fact that many authors regard the overdevelopment of lutein cells as bearing some relation to chorioepithelioma and mole pregnancy because it has been observed in these conditions. Seitz has examined the ovaries of women in various stages of pregnancy and finds that the proliferation of lutein cells is a normal accompaniment of every pregnancy, being derived from the follicles. They appear during the second month and are demonstrable up to the end of pregnancy.

2. Rupture of the Uterus.—Von Valenta observed fourteen complete ruptures of the uterus in 1,350 births; of the patients, three recovered, all of them after operation. All the non-operated patients died. It appeared that the quicker the patients were operated upon, the better was the recovery. The author believes in removing the child *per vias naturales* if it lies in the uterus after rupture, but by laparotomy if it has entered the abdomen.

In five cases supravaginal amputation was performed with extraperitoneal treatment of the stump; in one case a suture of the rupture was done, and in two instances total extirpation was practised. The author regards supravaginal amputation as the quickest and safest procedure.

RIFORMA MEDICA.

March 11, 1905.

1. Experimental Researches on the Immunizing and Curative Value of Antibacillary Serum (against Tuberculosis) (from Maragliano's Clinic, Genoa), By FIGARI and MARZAGALLI.
2. Contribution to the Study of Dercum's Disease, By GINO NORSIA.

3. Local Anæsthesia by Means of Stovaine and Stovaine-Adrenalin in General Surgery, By ALDO CERNEZZI.

1. **Value of Antibacterial Serum in Tuberculosis.**—Figari and Marzagallo, at Maragliano's advice, tried to obtain bactericidal serums from animals immunized against the bacillus of Koch. By injecting an aqueous extract of tubercle bacilli into rabbits, goats, and cows, they obtained serums possessing the highest possible agglutinating powers, but very slightly antitoxic and powerfully bactericidal. Virulent living tubercle bacilli emulsified with these serums for twenty-four hours did not affect rabbits even when double the fatal dose was given. The authors conclude that an antibacterial serum can be made which prevents and cures tuberculosis experimentally produced in animals. They report a case of advanced tuberculosis in a monkey which they cured with this serum. Ravenel, of the Phipps Institute of Philadelphia, repeated their experiments on rabbits, with the same results they record.

ROSSKY VRATCH.

February 26, 1905.

1. Cases of Menorrhagia Following the Extraction of Teeth, By A. A. ANOUFRIEFF.
2. The Question as to the After-Treatment of the Wound in the Bladder in Suprapubic Lithotomy, By P. A. BARATYNSKI.
3. On Experimental Cirrhosis of the Liver, By V. M. DANTCHAKOVA.
4. The Secretory Function of the Parotid Gland in Man (To be concluded), By E. A. ZHEROVSKI.
5. A Case of Tiger's Bite, By M. S. MASLOVSKI.

1. **Menorrhagia from Extraction of Tooth.**—Anoufrieff reports a rather unusual case of menorrhagia in a married woman aged twenty-five years, unipara, who was seized with extremely violent bleeding from the uterus soon after the extraction of some dental roots, under chloroform anæsthesia. She was brought to the hospital in a state of acute anæmia. A great variety of remedies were given, including ergot, strychnine, etc., internally and tampons saturated with various solutions as packing. Finally the uterus was curetted, a hot douche given, and a strip of gauze saturated in adrenalin solution was inserted into the uterus. Even this did not act immediately, but finally arrested the hæmorrhage for twenty-four hours, when the treatment had to be renewed so far as the packing was concerned. The scrapings showed the presence of chronic follicular endometritis. The author calls attention to this case as illustrating the connection of menstruation with the teeth, a subject not mentioned in the text books, although the connection of pregnancy with the teeth is well known. From a collection of cases of abnormalities of menstruation gleaned from literature, Anoufrieff found that during the periods there may be neuralgia, swelling of the gums, bleeding from the gums, and sensitiveness of the dentine. Dentists are aware of the fact that hæmorrhages may occur after the extraction of teeth when the operation is performed shortly before or during menstruation, while the same women undergo extractions without any evil con-

sequences between menstrual periods. The author, therefore, urges that dentists should not extract teeth during menstruation, and should even refrain from filling with gold or doing any other painful or exhausting work on the teeth during the periods. In gynecology and surgery the same principle should apply. It is best to follow the old rule, and not to operate during or shortly before or after menstruation, as there is danger of both infection and hæmorrhage. Some surgeons, however, have recently begun to disregard this rule.

2. **Closed or Open Treatment of Suprapubic Cystotomy Wounds?**—Baratynski studies this question concerning which controversy has been going on for some years past. The old method was to leave the bladder wound, as well as the abdominal wound, open, after suprapubic lithotomy. Since Bruns in 1857 sewed up the bladder after a cystotomy, the opinions of surgeons have differed as to the best method—the open or the closed—in the after-treatment of this operation. The author bases his conclusions on thirty-five cases of suprapubic cystotomy. To-day some surgeons, such as Tillmanns, believe that the closure of the bladder wound is never contraindicated. On the other hand, Nitze, Sonnenburg, Koenig deny the usefulness of this procedure in cases accompanied by infections of the bladder. Kukula thinks that in cases where the urine is aseptic (Do such cases exist?) the complete closure of the bladder is indicated. In cases with not very virulent infection of the bladder, complete suture can also be applied, but some of the stitches will probably tear through, although the final result is usually good in these cases. Finally, in virulent infection of the bladder the wound should be left open. The plan followed by the present author was somewhat similar to that just mentioned as recommended by Kukula. In cases with aseptic urine the wound was completely closed. When there was neutral or slightly alkaline urine, the cystitis was first treated, and if it improved the bladder wall was sutured completely. If the urine was much changed or markedly alkaline, the bladder was left open, and drained by means of iodoform gauze or by a drainage tube.

3. **Experimental Cirrhosis of the Liver.**—The ætiology of cirrhosis is by no means clear, but almost all the great writers on this disease agree that it is due to disturbances of digestion and to the action of bacteria of sepsis and their toxins. Kirikoff made the unique observation that staphylococci occur in the blood of patients with Hanot's cirrhosis. The object of the present research by Dantchakova was to test the theory of infectious origin of cirrhosis experimentally. For this purpose she made systematic injections of cultures of *Staphylococcus aureus* into rabbits (subcutaneously), and examined the livers of these animals. She found that she could produce acute effects on the liver, not only in its parenchyma, but also in the interstitial tissue. These were followed later by the formation of new connective tissue and the degeneration of hepatic tissue. The author thinks, from the appearances of cells in various stages of

development in the new connective tissue found in these livers, that the new connective tissue here was formed partly through a regeneration of old cells, but partly also through a differentiation of the lymphocytes.

5. **Case of Tiger's Bite.**—Maslovski reports the case of a soldier who had been bitten by a tiger near the station "Bikir," on the Ussurian Railway. The man was attacked by the tiger while patrolling the railway track, and after several ineffectual shots with his rifle, was obliged to grapple with the animal. He slit open the tiger's belly with his knife, but the tiger had time to throw himself at the man and severely lacerated his shoulders, wrists, and forearms. The latter were bitten while the soldier was trying to choke the animal by thrusting his arms down the tiger's throat. The result was that his wrist was opened on one side and his elbow joint on the other. The treatment consisted in a thorough disinfection of the wounds. Some of them were sutured, and the deeper ones were packed with iodoform gauze. A bichloride dressing was applied to the arms, which were placed in wire splints. The patient, however, developed a series of septic processes in several of the wounds, especially in the elbow joint. The wounds were enlarged, alcohol compresses and lysol baths were ordered. Antistreptococcus serum, stimulants, morphine, etc., were also used. The fever lasted two months and the wounds did not heal completely until three months after the injury. The patient's life was saved, but owing to the terrible disfigurement of his hands and arms he remained a cripple.

I. Cancer in and About the Mouth.

(a) The Importance of Early Diagnosis of Cancer in and About the Mouth, By FREDERIC C. COBB.

(b) The Results in Cases of Cancer of the Tonsils, Tongue, and Jaws, Operated in at the Massachusetts General Hospital During the Eight Years from January 1, 1892, to January 1, 1900,

By FARRAR COBB and CHANNING C. SIMMONS.

(c) The Results of Treatment of Cancer in and About the Mouth at the Boston City Hospital,

By HOWARD A. LOTHROP and DAVID D. SCANNELL.

(d) The Use of the X Ray in the Postoperative Treatment of Cancer in the Mouth, By E. A. CODMAN.

2. Thermotherapy as a Part of Physical Therapeutics,

By OCTAVE ROZENRAAD.

3. Weather Conditions at the Sharon Sanatorium,

By WALTER A. GRIFFIN.

4. A Suggestion for a Practical Apparatus for Use in Intrathoracic Operations,

By FRED T. MURPHY.

1. **Cancer About the Mouth.**—(b) Cobb and Simmons report a series of ninety-two consecutive cases of cancer involving the mouth that were observed at the Massachusetts General Hospital during the eight years from January 1, 1892, to January 1, 1900. They have been divided for convenience into four classes: (1) Cancer of the tongue, or floor of the mouth involving the tongue. (2) Cancer of the tonsil, which includes two cases of cancer arising from the mucous mem-

brane of the cheek, but involving the fauces at the time of observation. (3) Cancer of the upper jaw, including those arising from the antrum, alveolar process, or hard palate; and (4) cancer of the lower jaw, arising either from the mucous membrane over the alveolar process or more deeply placed, having a glandular origin, but soon involving the bone. Not all the patients were operated upon; some being too far advanced at the time of consultation, while others refused operation on being told the probable result. In general, it may be said that the statistics presented show that cancer of the mouth is not a hopeless disease. Eighty-three of the ninety-two cases were traced. Of the patients who underwent operation 16.3 per cent. were cured and 8.5 per cent. died from the operation. The remaining cases lived an average of two years after the operation. (c) Lothrop and Scannell summarize the results obtained at the Boston City Hospital thus: (1) The mortality of patients suffering from carcinoma in and about the buccal cavity (based on the statistics presented in this report) is extremely high, at least 90 per cent. (2) All unoperated patients die sooner or later of the disease, barring intercurrent affections. (3) The duration of life of operated patients as compared with those not operated is in favor of the former by an average of about three and one half months. (4) The comfort of the individual is distinctly added to (even if it be only temporary) by some sort of surgical intervention; such relief may be either mental or physical. (5) An early diagnosis of malignant disease about the buccal cavity is of the greatest importance, and a moderately radical excision of parts offers the greatest hope of a radical cure, commensurate with the comfort of the patient and the immediate risk to life. (6) Where there is extensive invasion of the parts, excision (if done at all) should be undertaken solely with the idea of palliation, without too serious interference with physiological function and without too great immediate risk. (d) Codman concludes: "We know that the x ray does make superficial cutaneous cancers disappear in some cases, and we cannot deny that it may allay the progress of deeply seated cancer; therefore, we may honestly say that it *might* do good in certain cases. Hopeless as it is, I believe that it is the most hopeful treatment we have after operation has failed."

2. **Thermotherapy.**—Rozenraad advocates the local use of superheated air in the treatment of many diseases. He does not go into details, but confines himself chiefly to noting the progress that this method of treatment has made in Germany.

4. **Intrathoracic Operations.**—Murphy describes and illustrates a head cabinet he has devised for the purpose of enabling the chest wall to be opened without producing collapse of the lung. The apparatus is simple. A box with a glass top is so arranged as to receive, through air tight opening, (a) the patient's head, (b) the anæsthetizer's hands, (c) the tube necessary for conveying the ether vapor (under whatever pressure is desired) and (d) the tube for carrying off the

consumed air and exhaled ether. This exit tube is connected to a water manometer, which serves to measure the pressure in the box. The apparatus has been successfully employed on animals.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

April 15, 1905.

1. Surgical Tuberculosis of the Abdominal Cavity, with Special Reference to Tuberculous Peritonitis,
By WILLIAM J. MAYO.
2. Study of the Economic Course of Consumption in Wage Earners,
By MARSHALL LANGTON PRICE.
3. Relation of School Methods to School Diseases,
By WILLIAM J. HERDMAN and JAMES H. MCBRIDE.
4. The Mortality of Appendicitis,
By CHANNING W. BARRETT.
5. An Experimental and Clinical Study of the Value of Clay Mixture Poultices,
By AUGUSTUS H. ROTH.
6. The Etiology and Pathology of Bronchopneumonia Complicating Measles,
By CHARLES F. CRAIG.
7. Immunity. Chapter XII.

1. **Surgical Tuberculosis.**—Mayo calls attention to the comparative frequency with which tuberculosis occurs in the abdomen. The Mayos have found localized tuberculous disease of the appendix twenty-nine times in 1,888 operations for appendicitis. Kelynack, in 121 cases of cirrhosis of the liver, found that ten per cent. had tuberculous peritonitis. Woodhead, in 127 autopsies in children (dead of pulmonary tuberculosis?) found one hundred with tuberculous mesenteric glands. In very many cases of tuberculous peritonitis in women the author has been able to prove the presence of tuberculosis of the Fallopian tubes. In general, it may be said that the author's article presents many disconnected facts which, taken as a whole, tend to show that tuberculosis may not improbably originate, in many cases, from infection acquired through the intestinal tract and that the bacilli either produce primary foci of disease within the abdomen or are carried by means of the lymphatics to more distant parts of the body. The practical lessons with regard to tuberculous peritonitis are thus stated by the author: "From the narrative of facts and observations so briefly set forth, I think we are justified in the belief that the failure of simple laparotomy and evacuation of fluid exudate in tuberculous peritonitis to maintain a high place in surgery is due to reinfection from lesions in the mucous membrane of the Fallopian tube, appendix, or some part of the intestinal tract. We have been treating a symptomatic peritonitis instead of removing the source of disease. That many times the infecting lesion cannot be discovered is true; and it is equally true that not all cases can be explained in this way. Experience teaches that under expectant treatment many of the primary lesions are cured by natural processes. Simple laparotomy and drainage aid recovery in a remarkable manner. Radical operation on the primary lesions in tuberculous peritonitis will greatly increase the percentages of cures and prevent reinfection of the peritonæum. In conclusion, it seems reasonable to suppose that tuberculous peritonitis has its origin in a local focus in practically every case, as is the fact in septic peri-

tonitis. Peritoneal reinfection may be prevented if the local focus can be removed. Whether the patient will regain and maintain general well being must depend to a large extent on whether the local focus thus removed is primary or secondary and, if secondary, as to the possibilities of cure of the chief seat of disease."

2. **The Economic Course of Consumption.**—Price presents a very elaborate statistical paper on the amount of partial and total disability produced by consumption and on the money equivalent of this loss. Few special conclusions need be emphasized. The chief point brought out by the paper is the terrific material loss to the individual and to the community produced by consumption.

3. **School Methods.**—Herdman and McBride assert that at present it is impossible to reach any general conclusions regarding the influence of school methods upon school diseases. Not until school children are medically inspected before, during, and after their school courses shall we be in possession of the facts on which to base rational conclusions.

4. **Appendicitis.**—Barrett's conclusions, condensed, are: (1) To decrease the mortality of appendicitis an early diagnosis is of the first consideration. (2) All troublesome appendices should be removed without waiting for an acute attack. (3) All acute cases should be dealt with surgically. (4) Cases of perforation or gangrene, with localized abscess, should be operated in with drainage or removal of the appendix. (5) Cases with perforation or gangrene without a wall of adhesion are in still greater need of an outlet for the infection, to lessen the tendency of infection to travel inward. (7) A case of acute appendicitis should be operated in at any time if the patient's condition will admit of an operation, unless the patient is rapidly and beyond a question of doubt convalescing. And in this latter case we should wait until all acute symptoms have passed. (9) The proper treatment, as indicated above, does not contraindicate the use of stomach lavage or the withholding of food and, when proper, these things should be employed, with or without operation. (10) Life is not the only consideration. Time of cure and after-conditions are important.

AMERICAN MEDICINE.

April 15, 1905.

1. Hysterectomy for Fibroids of the Uterus, with a Report of 250 Operations,
By JOHN B. DEEVER.
2. The Radical Treatment of Gastric Hemorrhage, with a Review of a Personal Case and 99 Collected from the Literature Since 1900,
By F. GREGORY CONNELL.
3. Paratyphoid Fever with Report of Six Cases,
By JOHN NORMAN HENRY.
4. Chronic Eczema as a Complication of the Senile Degenerations,
By MEDWIN LEALE.
5. Post Partum Hemorrhage,
By H. H. LOVELAND.
6. A Contribution to the Pathology of Sciatica,
By J. RAMSAY HUNT.

1. **Fibroids.**—Deever holds the following opinions regarding fibroid tumors of the uterus

and their treatment: Fibroids of the uterus do not require removal unless they are productive of symptoms, but when they do become symptom-producing, they should be removed promptly, before the patient has been weakened by toxæmia, hæmorrhage, or sepsis. Abdominal supravaginal hysterectomy is the operation to be preferred in the vast majority of cases. Myomectomy is applicable only to younger women in whom the tumors are few in number and subperitoneal in character. Panhysterectomy is to be employed only when intraligamentary growths, whether uterine or ovarian, render the performance of supravaginal amputation difficult or dangerous. The ovaries, or a part of one ovary should be preserved in every woman who has not reached the age of the menopause, unless they are distinctly and indisputably diseased, or unless their retention would needlessly prolong and complicate the operation.

2. **Gastric Hæmorrhage.**—Connell states that the radical methods for treating gastric hæmorrhage are: (a) Direct: Excision of ulcer; partial gastrectomy, or pylorotomy; ligation of the principal artery; cauterization of curettement of the bleeding point; ligation of the mucous membrane, *en masse*; ligation of all coats. (b) Indirect: Gastroenterostomy; pyloroplasty; gastrotomy. Each of these methods of treatment is described and discussed. This survey would seem to justify the following conclusions: (1) After palliative treatment has failed to effect a cure in a reasonable time, and in all cases in which three or more profuse acute hæmorrhages have occurred, that surgical treatment is demanded. (2) Of the various methods of surgical intervention, unless distinctly contraindicated, the direct method should be preferred. The indirect method is indicated when the direct cannot be carried out, and sometimes as a supplementary operation after the direct procedure. (3) Of the direct methods, the choice will lie between ligation of the mucous membrane, excision of the ulcer, or pylorotomy and Andrews's operation. (4) Of the indirect methods, gastroenterostomy will be the operation performed. The mortality rate to be expected after radical operation will depend upon various conditions, such as the previous history and the present condition of the patient, the number and character of the hæmorrhages, and whether the operation is being undertaken as a prophylactic or a life saving measure. The percentage of fatalities has been decreasing gradually. The author ends his article with abstracts of the one hundred cases he has been able to collect.

6. **Sciatica.**—Hunt shows how inadequate is our knowledge of the pathology of sciatica: From the years 1764 to 1878, 11 pathological observations have been recorded. Of this number 3 were negative, including 1 case with microscopical examination (Gubler and Robin). In 8 cases the result was positive, the nerve was found enlarged, reddened, and cedematous. This group included only two microscopical examinations, both negative, that of Leudet, who simply described the nerve fibres as unaltered, and that of Fernet (Vul-

pian's laboratory), in which careful examination failed to reveal any histological changes. Recently the author had under observation a case of undoubted sciatica. The patient died of croupous pneumonia. The sciatic nerve was obtained and a careful pathological examination of it was made. The findings are reported in detail. The essential thing to be noted is that the nerve showed no inflammatory reaction. There was only a jelly-like deposit in the nerve sheath, quite structureless histologically and unaccompanied by inflammatory changes. The author holds that this peculiar deposit must be looked upon as the underlying condition in certain forms of sciatica. The acceptance of a lesion of this nature does not, however, exclude the possibility of a true interstitial inflammation, with cellular infiltration, organization, and permanent damage to the nerve. It would seem fitting, however, to discriminate between this form, which is properly speaking a neuritis, and that under discussion in which the sheath is the seat of a structureless deposit of obscure origin.

MEDICAL NEWS.

April 15, 1905.

1. Intracranial Traumatic Hæmorrhage,
By J. SHERMAN WIGHT.
2. A Preliminary Report of the Use of Diphtheria Antitoxine in Epidemic Cerebrospinal Meningitis,
By FRANCIS HUBER.
3. Some Points in the Construction of a High Frequency Machine,
By CLARENCE A. WRIGHT.
4. Report on the Use of Stovaine,
By C. G. COAKLEY.
5. On the Treatment of Chronic Osteomyelitis and of Chronic Bone Cavities by the Iodoform Wax Filling,
By CHARLES A. ELSBERG.
6. The Significance of Epigastric Pain,
By A. M. POND.
7. Gastrointestinal Conditions in Epilepsy,
By J. W. McLAUGHLIN.

1. **Intracranial Hæmorrhage.**—Wight covers in a general way the subject of intracranial hæmorrhages. Special attention is devoted to so called traumatic apoplexy. The author distinguishes three varieties of this condition: (1) Traumatic apoplexy occurring simultaneously with the injury. (2) Traumatic apoplexy occurring shortly after the injury. (3) Apoplecticiform symptoms occurring long after the injury. Five cases are reported. Four are taken from the literature and the fifth was seen by the author in consultation.

2. **Diphtheria Antitoxine in Meningitis.**—Huber reports using diphtheria antitoxine in a number of cases of epidemic meningitis with rather encouraging results. In some of the cases 1,500 to 2,000 units were injected directly around the cord by means of a lumbar puncture. Particulars of the cases treated are not given, the present paper being only a short preliminary note. A more detailed paper will appear shortly.

3. **High Frequency Machines.**—Wright devotes his paper chiefly to the consideration of the physical data which bear on the construction of a high frequency machine, whose output of current will approximately equal, if not even exceed, one ampère.

5. **Wax Filling.**—Elsberg has treated a number of cases of osteomyelitis according to the method advocated by Mosetig-Moorhof. This consists in filling the bone cavity by means of iodoform wax. The results obtained by the author lead him to strongly recommend the procedure. His own technics differs from those recommended by Mosetig-Moorhof. The author uses twenty per cent. iodoform wax in the place of sixty per cent. wax, and fills the cavities by pressing in place small pieces of the preparation instead of pouring the completely melted wax into the cavity to be filled.

6. **Epigastric Pain.**—Pond's paper is a plea for accurate diagnosis in patients complaining of pain in the epigastric region. He asserts his belief that most of this kind of pain is due to some gross lesion of either the stomach or gall bladder.

7. **Epilepsy.**—McLaughlin has had good results in six cases of epilepsy by attending to the gastrointestinal condition of his patients. He therefore urges that this phase of epilepsy should receive greater attention.

MEDICAL RECORD.

April 15, 1905.

1. Cerebrospinal Meningitis—Epidemic and Sporadic,
By GRANT GOULD SPEER.
2. Recent Studies in the Diagnosis of Rabies,
By DANIEL W. POOR.
3. Modern Methods of Treatment in Obstetrics and Gynecology,
By J. A. SCHMITT.
4. Some Points of View in Regard to the Time When to Perform the Myringotomy and the Mastoid Operation,
By EMIL AMBERG.
5. Decapsulation of the Appendix,
By A. E. ISAACS.
6. Tuberculous Testicle and the X Ray,
By W. B. DE GARMO.
7. Granulation Wound Adhesions, with a Preliminary Report on a New Application in Preventive Treatment,
By FREDERIC GRIFFITH.

1. **Meningitis.**—Speer writes quite a complete formal paper on cerebrospinal meningitis. It is in the nature of a composite picture of what has lately been written about the disease. A summary of the article follows: Cerebrospinal meningitis when first recognized was purely epidemic in character, and is now endemic in large cities. Its method of transmission from place to place and person to person is unknown. According to the latest and best investigators, the exciting cause of the epidemic form is the diplococcus intracellularis meningitidis. And no evidence has been produced to prove that the cause of epidemic and sporadic cases is not the same. The probable entrance of the pathogenic germ into the system is through the respiratory tract, especially that portion covered by the Schneiderian membrane. And its point of attack and usual seat of greatest activity is the base of the brain, from which it involves other portions of the meninges of the brain and spinal cord. Its action is that of a septic invasion, and its symptoms a combination of toxine poisoning, nerve irritation, and pressure. The rate of mortality in late epidemics has been about 50 per cent., which may be lowered by a better

agreement among the profession regarding methods of care and treatment. Spinal puncture is a requisite of exact diagnosis, but as a method of treatment it is still in the experimental stage and leaves much to be desired. Old methods of treatment may be made effective and reliable if used with decision and pushed to the limit of therapeutic effect. Cerebrospinal meningitis in its worst form is amenable to treatment.

2. **Rabies.**—Poor has conducted a series of studies in the laboratory of the New York Board of Health bearing on the diagnosis of rabies. He concludes that, while further studies are needed to fully establish the value of Negri's method of reaching a correct diagnosis, yet it seems probable that this method will prove itself to be a reliable one for the rapid diagnosis of rabies.

3. **Obstetrics and Gynecology.**—Schmitt gives what he considers to be the most modern methods for the treatment of puerperal sepsis, eclampsia, generally contracted pelvis, and carcinoma of the uterus. We note that he favors antistreptococcus serum in sepsis; splitting the kidney in some cases of eclampsia; Gigli's operation for contracted pelvis and in cancer the radical operation of hysterectomy, that is the operation which attempts to clear away as many of the infected lymphatic glands as possible.

6. **Tuberculous Testicle.**—De Garmo reports a case of tuberculosis of the testicle which was cured, apparently, by x ray treatment. The case is placed on record for what it is worth.

LANCET.

April 1, 1905.

1. On the Growth of Cancer,
By E. F. BASHFORD.
2. Industrial Anthrax (*Milroy Lectures, III*),
By T. M. LEGGE.
3. The Physiology and Treatment of Surgical Shock and Collapse (*Hunterian Lectures, III*),
By J. P. L. MUMMEY.
4. Periculis Sinistra,
By H. D. ROLLESTON.
5. The Vibrating Sensation in Affections of the Nervous System and in Diabetes,
By R. T. WILLIAMSON.
6. Notes on a Case of Pressure Stasis,
By R. L. JOYNT.
7. Carcinoma of the Bronchus and Liver Associated with Glycosuria in a Youth,
By G. HALL and R. H. TRIBE.
8. A Soluble Button for Intestinal Anastomosis,
By P. PATERSON.
9. A Note on a Case of Graves's Disease,
By W. B. JONES.

1. **Cancer.**—Bashford briefly summarizes the results of the investigations made under the Imperial Cancer Research Fund, as follows: 1. Cancer is identical in all vertebrates and in growing accommodates itself in a striking manner to the time limitations imposed by the compass of life in different animals. 2. Under favorable experimental conditions the growth of cancer is undefined, of enormous, and, as far as he can judge, limitless amount. 3. Artificially propagated cancer displays all the characteristic features of the growth of sporadic tumors. 4. The growth of artificially propagated cancer is due to the continued proliferation of the parenchyma cells. He has confirmed this conclusion, originally advanced

by Jensen, on his own tumor and on four other different carcinomata. 5. The artificially propagated parenchyma makes the reaction of the host subserve its own needs. 6. Artificially propagated tumors cause no symptoms in the organism to which they have been added. 7. The power of differentiation is definitely in one direction only, even three and a half years after separation from the original host. 8. The number of chromosomes constant for the healthy body tissues is retained, notwithstanding the recurring reduction of this number to the exact half. 9. The balance of evidence is in favor of the growth being interrupted and not uniform. 10. From the standpoint of therapeutics the investigations establish the early surgical treatment of cancer and of the conditions suspicious of cancer, upon an experimental and rational basis. Artificially propagated tumors produce metastases as do sporadic tumors. Sufficiently early removal of the local transplanted tumor removes metastasis from the region of possibility.

3. **Shock and Collapse.**—Mummery, in the third of the Hunterian lectures, takes up the treatment and prevention of shock and collapse by the introduction of fluids into the circulation. There are four principal ways in which this may be done: (1) By intravenous infusion; (2) by intra-abdominal infusion; (3) by rectal injection; and (4) by subcutaneous injection. The intravenous infusion of salt solution or physiological serum will raise the blood pressure in all degrees of shock. As a method of treatment in shock it is disappointing, as its action is fleeting and it cannot be continued indefinitely. In the collapse of severe hæmorrhage it is effectual and lasting in its effects. The introduction of saline solution into the abdomen at the end of an abdominal operation is a valuable method of combating shock, and is not contraindicated by the presence of pus in the abdominal cavity. An effectual method of treating shock is by the administration of drugs, such as adrenalin, hemisine, and ergot, which raise the blood pressure by increasing the peripheral resistance independently of the nerve centres. The few clinical cases in which these drugs have been used are very encouraging, and their use instead of the stimulants now generally employed, will probably result in the saving of many letters. Like sepsis, shock can be prevented much more easily than it can be cured, and it is to its careful prevention rather than to its treatment that we must look to get rid of this source of danger in the operations of the future. With the exception of abdominal operations the method of blocking the main nerves with cocaine seems to afford a ready and most efficient way of completely preventing shock in even the most severe of surgical operations. Morphine, administered both before and after an operation, is useful in preventing shock. In all forms of sudden collapse, including the collapse of chloroform poisoning, the intravenous administration of adrenalin is of immense value in assisting to restore the patient's life. This drug, by raising artificially the blood pressure, allows the heart and the vital nerve centres to resume their functions very easily. It should prove

of great value in resuscitating drowned persons and in other similar emergencies.

4. **Pericolicitis Sinistra.**—Rolleston calls attention to a group of cases which resemble appendicitis, in that the prominent feature in both is the involvement of the visceral peritonæum; only it is on the left instead of on the right side of the abdomen. The cases may give rise to different conditions; there may be (1) local peritonitis of comparatively slight intensity around the descending colon or the sigmoid flexure; (2) a local abscess in connection with the descending colon which may eventually burst into the general peritoneal cavity and set up (3) general peritonitis.

5. **Vibration in Nervous Diseases.**—Williamson's conclusions are as follows: 1. In the normal condition the vibrating sensation, tested by placing the foot of a vibrating tuning fork over the styloid process of the ulna, the internal malleolus, and the inner surface of the tibia about the middle of the bone, is probably always present. 2. In early tabes it may be lost in the legs before impairment of other forms of sensation occurs and before ataxia or Romberg's sign can be detected. 3. In certain cases of spastic paraplegia it may be lost in the legs when other forms of sensation are not affected. 4. In some cases of diabetes mellitus and chronic glycosuria it is lost when sensation in other respects is normal. 5. From these facts it is evident that sensation cannot be declared to be normal until the vibrating sensation has been tested. Though the loss of the vibrating sensation is a symptom of considerable interest it is at present too early to say what its diagnostic value will be in the future.

8. **A Soluble Intestinal Button.**—Paterson states that one of the great disadvantages to the use of mechanical supports in performing intestinal anastomosis is the uncertainty that the support will be discharged after it has fulfilled its function, it being sometimes necessary to perform a second operation for its removal. If a button could be obtained which would be easy to manipulate and which would remain *in situ* for the necessary length of time without, in the meantime, injuring the intestine and then undergo solution, the principal objection to this method of intestinal union would disappear. After many experiments he concludes that gelatin which has been treated with chrome alum meets these requirements. It can be prepared in such a manner as to be more or less resistant to the action of the digestive secretions according to the activity of these in the part operated upon or to suit the particular purpose the surgeon may have in view. The method of fixing the support is almost the same as that employed in using Murphy's button.

7. Ship Beri-Beri, By G. A. TURNER.
8. Notes on Cases of Spirillum Fever in Uganda, By A. D. P. HODGES and P. H. ROSS.

1. **Dermatological Therapeutics.**—Morris has been led to the conclusion that the general principle of treatment of chronic diseases of the skin is to produce reaction. As a rule, without reaction there is no cure. Reaction, which is simply response to stimulus, varies not only in degree, but in kind. The response varies according to the tissue or organ stimulated. The mechanism is virtually that of inflammation—passing from simple hyperemia to necrosis. Reaction may be caused by the external application of various drugs or by the use of physical agents, such as heat, light, the x rays, and radium, by drugs administered internally, by toxic substances generated within the body as the result of processes set up in the natural course of the disease, or by the artificial production of like conditions by the injection of serums or the administration of organic extracts; or by the combined use of external and internal remedies. It is usually better to produce reaction by a local application. Among the external medicaments causing reaction the writer discusses soft soap, sulphur, tar, salicylic acid, pyrogallol, and especially chrysarobin. Of physical agents, simple baths, hot or cold, and heat produce the mildest form of reaction. More powerful are light, x rays and radium; the author gives a summary of the results of five years' experience with these agents. Among the internal agents may be mentioned tuberculin, streptococcus serum, leprolin, thyroid extract, and adrenal extract; all of these produce their therapeutic effect by causing reaction.

2. **Constipation.**—Lane states that in chronic constipation the cæcum is progressively distended and forced downwards and inwards into the true pelvis. This results chiefly from its weight. This forcing down of the cæcum is much helped by the sedentary position assumed during defecation. The squatting attitude is the correct one as the pressure exerted by the thighs forces the cæcum and transverse colon up into the abdomen. The inflammation of the colon and cæcum consequent upon their excessive distention, produces an adhesive process between the bowel and the peritonæum. The bowel thus becomes fixed, and it is less able to perform its normal functions and its muscle wall wastes. In many of these cases the kidneys are mobile. One of the most conspicuous of the clinical symptoms besides the constipation, is a fullness and tenderness in the region of the cæcum. The symptoms due to the absorption of toxins all tend to produce an appearance in the patient of premature senility, and the loss of fat is very conspicuous. Mental depression is often present to a marked degree. As regards surgical treatment the choice lies between the

division of bands and adhesions, and the establishment of direct continuity between the lower end of the ileum and the termination of the large bowel. In women it is better to proceed at once to the deflection of the fecal contents from the greater part of the large bowel.

4. **Leucopenia.**—Rogers has investigated the diagnostic and prognostic value of the leucopenia of cachexial fever and kala-azar. His conclusions are as follows: 1. A very marked decrease in the leucocytes is always found in uncomplicated cases of cachexial fever, and when they number below 2,000 per cubic centimetre this is almost diagnostic of the disease, but may rarely occur in true malarial cachexia. 2. In cachexial fever the white corpuscles are reduced to a greater degree than the red, so that the ratio falls below one to one thousand in all uncomplicated progressive cases. This is rarely so in true malarial cachexia, while a reduction in the ratio to below one to fifteen hundred appears to be quite diagnostic of cachexia from other Indian fevers. 3. The most marked degrees of reduction of the leucocytes, and especially of the polynuclears, is of bad prognostic import, and vice versa. 4. Red marrow tabloids are of great value in increasing the leucocytes, and this increase may take place during the continuance for months of intermittent fever, and be then followed by cessation of the fever and complete recovery. 5. High remittent fever is accompanied by progressive deterioration of the blood and general condition, but it may be often to a large extent reduced to the less injurious intermittent form by continued large doses of quinine, combined with red marrow. The best results yet reported have been obtained by those who carry out vigorous quinine treatment.

5. **Mediterranean Fever.**—Ross and Levick have experimented in the hope of discovering the true nature of the transmission of Mediterranean fever. Both writers being non-immune to the disease, they exposed themselves to infection by various means of experimental transmission:—by direct contact, fomites, etc.; by inhalation of infected dust; by infected water; and by means of mosquitoes. Up to the present all these methods have failed to reproduce the disease.

7. **Beri-Beri.**—Turner's article is based on his experience as port health officer at Table Bay. Among the conspicuous symptoms of beri-beri he mentions œdema, irregularity of the heart's action, paralysis of very varying degrees, tenderness of the calves, and irregularity of the knee jerks. As regards the ætiology of the disease little reliance is to be placed upon the theories which ascribe it to want of ventilation, to faulty dietary, or to metal poisoning. The evidence tends to support Manson's theory that beri-beri is a place disease, and also that it is a germ disease, but probably not communicable from man to man. It is a disease caused by the absorption of a toxine formed by an organism outside of the body. The organism may exist in the water or mud of tropical rivers, be taken on board ship by means of cargoes, ropes, anchors, etc., and so transmitted to any susceptible members of the crew.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of March 8, 1905.

Dr. HOWARD M. FUSSELL in the chair.

A Hæmoglobin Scale and Color Test Book.—

Dr. H. E. WETHERILL called attention to his hæmoglobin scale and color test book. He also showed a new hæmatocrite which measured in a two way motion instead of one, and gave 25,000 revolutions a minute.

Fracture of the Cervical Spine.—Dr. CHARLES W. BURR exhibited a patient with an old fracture of the cervical spine. He was fifty-six years of age, and had fallen in November, 1898, from a cart, striking on his neck and shoulders. He was unconscious for a time and was taken to a hospital. At first he had severe pain in the neck, shoulders, and both arms. He could not move the arms and could not walk. He stated that he could move the legs a little. About six months later he was brought to the Philadelphia Hospital. At that time he could walk fairly well with short, stiff steps. He held his neck very stiff, and movements in the arms were limited by rigidity and by weakness. The grip was very weak. The deep reflexes were increased. A skiagraph revealed a fracture of the body and lamina of the fifth cervical vertebra. At the present time he walked well. His head was held stiff. He could move it a little, but with pain. There was considerable power of movement of the arms, with rigidity. The knee jerks were a little increased. The plantar jerks were normal. There was a little muscular wasting in the deltoids, but none elsewhere. There was some spasmodic retention of urine.

Dr. M. K. KASSABIAN gave some statistics of fractures, showing that a very small percentage represented those of the spine. In his own 1,500 cases of fracture there had been only four per cent. of fracture of the spine.

Dr. MORRIS BOOTH MILLER stated that in such a fracture an operation should be undertaken only when there was pressure upon the cord or from bone. Ankylosis gave a fair chance of slow absorption of hæmorrhage and gradual restoration of function. To secure that, no device was better than a modified jury mast.

How Can the Physician Profit by Preventive Medicine?—Dr. J. MADISON TAYLOR, in this paper, presented evidence to show that it was necessary that preventive medicine should be exhibited to the profession as a means of advantage to themselves as well as to the community. He submitted that the relationship of the physician to the patient was on the wrong basis; the practitioner should be given free opportunity to inspect the members of a household at regular periods or at will, and not called only when there was illness; disease was now being studied from the standpoint of economics, hence prevention was to be welcomed as a source of general wealth; legislation could be made more effective if physicians would do their part toward the prevention or

limitation of preventable disease; physicians should more clearly point out the ways to reform and educate the public; they should accept the authority of the health boards more cordially and work with them to accomplish results.

He recommended that physicians should adopt a different fee system, and stated that it was a false position for the physician to earn no fee except by being invited to meet exigencies; better, he said, to adopt the plan long since found necessary by lawyers, of demanding a retaining fee or a yearly stipend of the householder, thus giving them access to the house to rectify constitutional peculiarities and save from peril. He alluded to the neglected duty of the physician of discouraging the use of many medicines, bitters, tonics, cough medicines, and the like, whose chief attractiveness lay in the contained alcohol or narcotics.

The Osmic Acid Treatment of Tic Douloureux.—Dr. W. WAYNE BABCOCK reported a case of trifacial neuralgia of extreme severity. The conditions had persisted for thirty-five years, despite eight operations, including two attempts to remove the Gasserian ganglion, and the excessive use of drugs had at one time led to temporary insanity. About nine months ago a two per cent. solution of osmic acid, under cocaine anæsthesia, had been injected into the inferior dental nerves. More recently the infraorbital, palatine, and supra-orbital nerves were injected. The patient had gained thirty-five pounds and his physical condition was revolutionized. The case was cited to indicate that osmic acid injections might be of value in cases of the most persistent and pronounced type of tic douloureux. No major operation, he stated, was warranted in the treatment of trifacial neuralgia until the futility of osmic acid injections into the peripheral nerve trunks had been proved.

Dr. L. J. HAMMOND called attention to the relations of the nerve fibres constituting the trifacial, and thought that absolute cure of these pains should not be expected until not only the trifacial, but the different branches of the fifth nerve, were dealt with.

The Problem of the Treatment of Laryngeal Tuberculosis.—Dr. W. G. B. HARLAND read this paper, which gave briefly what is known about the prevalence and natural history of tuberculosis of the larynx. The paper stated that the vocal cords, interarytænoid folds, and arytenoids were the parts most often affected, involvement of the epiglottis or epiglottic folds being more serious. Most forms of the disease pursued a harmless chronic course; oedema and deep ulceration, however, were dangerous. The laryngeal lesion probably did little harm, except when it caused dyspnoea, pain, or difficulty in swallowing; it formed an index of the general health and resistive power. Treatment was directed toward lessening irritation in the upper air tract, toward healing ulcerations, and toward building up the general health. The x ray he had found to be of use in some cases. He thought that serum therapy promised much.

Dr. W. WAYNE BABCOCK referred to a case of laryngeal tuberculosis seen within the last four or five months. On the day he first saw the pa-

tient she had received an intralaryngeal application. She had dyspnoea and became unconscious. A rapid tracheotomy was done, after which she improved and gained in weight. The tube was removed. Further applications were not made by the laryngologist, for fear of the oedema, but after two or three months the oedema again developed. A second tracheotomy was done, and since that time the patient had worn a tube continuously. Her voice was better and she had gained in weight.

Dr. ROSS SKILLERN thought that if the laryngologist gave the greatest possible amount of relief with the smallest amount of actual manipulation of the diseased structures, he was doing good work.

Dr. L. J. HAMMOND had operated in eight cases of laryngeal phthisis in the past sixteen or eighteen months with good results. He thought the operative procedure was based upon rational principles, in that in this condition, as in a tuberculous condition of the joints, the best treatment was to put the parts at rest.

Dr. GEORGE E. FEAHLER mentioned a case, referred to him by Dr. Cleveland, in which he was making the x ray applications externally, using the tube of high vacuum and at a distance of from fifteen to twenty inches. Distinct improvement had been noted in the case by Dr. Cleveland.

Dr. HARLAND referred to the surgical treatment as he had observed it as rather unsatisfactory.

Book Notices.

A Textbook of Histology. By FREDERICK R. BAILEY, A. M., M. D., Adjunct Professor of Normal Histology, College of Physicians and Surgeons, Medical Department, Columbia University, New York city. Profusely illustrated. New York: William Wood & Co., 1904. Pp. xiv-481.

The general science of histology at the present time is fairly fixed in its outlines, and the subject matter, which is useful to the student body, can be collected within sharply defined limits. But little that is novel can be expected at present from a new textbook, if we except the cytology of the cerebrospinal system. Either a new book should show improvement in arrangement over those which have preceded it, thus rendering the subject matter more easily accessible to the student mind, or the illustrations must bring something new or must be better than those previously produced.

The work just published certainly fulfills these conditions and offers to the student of medicine a well arranged, clearly written textbook, sufficiently comprehensive for the purpose, yet not obscured by details. The medical student does not intend to pursue histology as a science for itself; he merely desires the fundamental facts which he must acquire before it is possible to advance to the study of tissues altered by disease. A book of this type, which is intended for medical teaching, should therefore chiefly concern itself with human histology, and though perhaps somewhat less useful for the preliminary education of students who intend to devote themselves to research in after life than one which approaches histology from a broader point of view,

such a book is yet the best one to place in the hands of the beginner in medicine.

The arrangement of the chapters, the selection of the text type, and the division of the paragraphs by the use of different sizes of heavy face type for equivalent sections have all been carefully considered and the result is most successful. A considerable number of the illustrations have been drawn from the author's preparations, and we must congratulate him on the successful issue of many of the reproductions. The artist improves in his work as the text progresses, the earlier sketches not having been sufficiently reduced to subdue the grain of the paper upon which they were drawn, but the later preparations are most excellent. Some of the drawings illustrating the structure and development of bone, those showing the anatomy of the lungs and bronchi, and especially the sketches of the kidney, are equal to the best German work. Photomicrography has been used but little, which is perhaps just as well so far as the student is concerned, though the modern improvements in the art might warrant the use of three color color plates, some beautiful examples of which have lately been produced. The reproductions of the exquisite colored plates from the histological atlas of Szymonowicz show very well the loss of character which results in attempting to produce a colored plate in monochrome. These are the least successful of the illustrations in the text and should be discarded in a future edition. The latter half of the book, especially the chapter on the nervous system, contains but few original drawings, but those selected have been well chosen. It seems a pity that the color schemes from Lenhossek, illustrating the structure of the spinal cord, could not have been reproduced as in the original, instead of using hatching to represent the tints.

Throughout the book the author has been most conservative in his selection and presentation of subject matter, and the student will find the volume a safe and accurate guide for the study of normal histology.

Miscellany.

Cargile Membrane.—*Medical Notes and Queries*, for March, 1905, explains that cargile membrane is peritonæum from the intestine of the ox, subjected to certain processes and finally sterilized. It is a thin, translucent, almost homogeneous, acellular material in many ways resembling gold beater's skin. It is intended for use between denuded peritoneal surfaces, over stumps, or, in fact, any wounded areas, to prevent the formation of adhesions, the membrane itself undergoing absorption after a certain length of time. The exact practical value of the membrane has never been satisfactorily determined, though Dr. Robert Morris, of New York, gave a very favorable report after a series of experiments upon rabbits. Recent experiments in the laboratories of the Jefferson Medical College Hospital by Dr. A. B. Craig and Dr. A. G. Ellis, reported by them at the Philadelphia Academy of Surgery, February 6, 1905, did not yield such encouraging results. The experiments were made by Dr. Craig upon dogs and included operations in the peritoneal and cranial cavities and upon nerves.

and tendons. The membrane was found of but little value in the peritoneal cavity, adhesions forming in essentially every instance. Contrary to expectations, the membrane did not stay in place unless sutured. In the cranial cavity and around tendons and nerves the membrane appears to be of some value in preventing adhesions; the chromicized variety resists absorption longest and in general gives the best results. Histological study of the tissues by Dr. Ellis, the first microscopic investigation of this subject, showed that the membrane acts as an irritating foreign body, new tissue being formed around it in every instance. The ultimate fate of the membrane is absorption, which appears to follow the action upon it by lytic substances in the body fluids. This is indicated by the sections and particularly by the changes occurring in pieces of the membrane enclosed in sealed celloidin capsules, which were placed for varying periods of time in the peritoneal cavities of the dogs employed in the experiments. Phagocytosis as a factor in the removal of the membrane in the tissues was not demonstrable.

Fewer Matriculates in Medicine in Great Britain.—The desire to enter the ranks of British medicine is not so keen as in days gone by. The statistics, published in the *Medical Register*, for 1905, show that there has been a steady decline in registrations during the past decade. The high water mark was reached in 1893, when 1,579 registrations were made—770 in England, 638 in Scotland, and 171 in Ireland. Since then the figures have shown an annual decrease, 1904 being the lowest recorded (1,168) since 1881 (1,053). In 1904 the percentages of total registrations were 53.4 for England, 33.3 for Scotland, and 13.3 for Ireland. The principal decline during the decennial period has been in England and Scotland; Ireland contributing a fairly steady number of registered medical men to the world annually. The averages of restorations to the *Register* during the past five years were 105. During 1904, 558 names were removed from the *Register* on evidence of death, 2 on ceasing to practise, 95 failed to answer the registrar's inquiries regarding change of address and were erased, and 2 were struck off under the penal clauses (sections 28 and 29 of the Medical Act). Of the total number of persons registered from 1858 until January 1, 1905 (67,214), there are 38,492 names in the present *Register*.

Disturbances of Digestion in Infants Resulting from the Use of Too High Fat Percentages.—Holt, in the *Archives of Pediatrics*, for January, 1905, discusses this question and cites illustrative cases in which infants suffered great disadvantages from too free use of fats (cream). He thinks the errors into which both physicians and patients too frequently fall are due to their fondness for Jersey or Alderney milk and cream. Milk from herds which yield four or four and a half per cent. of cream is to be preferred. One of the chief causes of failure in feeding from the milk laboratory has been the excessive use of fat, and physicians are especially prone to make this mistake in cases in which they hope to overcome chronic constipation by the free use of cream.

Such mistakes can often be avoided if the physician knows approximately the richness of the milk in fat, that is, the percentage of cream or top milk. The mistake is often made of treating all specimens of milk and cream alike, using them in accordance with the prescribed formula of some work on infant feeding.

It is of importance that the physician should ascertain at the milk laboratory the percentage of fat in the milk which he is prescribing and calculate his dosage of cream accordingly. It is also desirable that he should examine the milk and cream for his own information. If he habitually uses milk from the same dairy his calculations as to percentages of fats will be fairly accurate. A Babcock tester or one of its modifications may be used to determine the quantity of fat or the milk may be tested and analyzed at a milk laboratory. He should learn to think in percentages. There is a limit to the quantity of fat which the infant stomach will tolerate and it is desirable to ascertain it and not go beyond it. The author has found it unwise to use more than four per cent. of fat for the average child. Bad results will surely follow the use of larger quantities than this. If there is gastric or intestinal indigestion it may be necessary to decrease it below four or even three per cent.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending April 14, 1905:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Florida—Jacksonville	Apr. 1-8	3	
Illinois—Cairo	Apr. 3	5	
Illinois—Danville	Apr. 1-8	3	
Louisiana—New Orleans	Apr. 1-8	26	1
Louisiana—Pointe Coupee Parish	Apr. 1-8		
Louisiana—St. James Parish	Mar. 1-31	Several.	
Louisiana—St. John Parish	Mar. 1-31	1	
Michigan—Grand Rapids	Apr. 1-8	2	1
Michigan—At 47 localities	Mar. 18-25	Present.	
Mississippi—Natchez	Mar. 25-Apr. 8	2	
Missouri—St. Louis	Apr. 1-8	28	8
Nebraska—Omaha	Apr. 1-8	1	
Nebraska—South Omaha	Apr. 1-8	1	
New York—New York	Apr. 1-8	4	
North Carolina—Goose Creek	Apr. 1-8	1	
North Carolina—Hog Island	Apr. 3	50	
Ohio—Cincinnati	Mar. 31-Apr. 7	6	
South Carolina—Charleston	Apr. 1-8	2	
Tennessee—Memphis	Apr. 1-8	1	
Smallpox—Foreign.			
Africa—Sierra Leone	Mar. 10-17	240	
Brazil—Bahia	Feb. 25-Mar. 11	24	1
Brazil—Escada	Mar. 11	8	Epidemic.
Brazil—Rio de Janeiro	Mar. 12	8	
Ecuador—Guayaquil	Mar. 7-14	2	4
France—Paris	Mar. 18-25	29	6
France—St. Etienne	Mar. 1-15	2

Peru—Cajamarca.....	Mar. 10.....	Present.	

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending April 12, 1905:

CUMMING, H. S., Passed Assistant Surgeon. Granted leave of absence for ten days from April 15th.

DREW, A. D., Acting Assistant Surgeon. Granted leave of absence for two days, March 8 and March 24, 1905, under paragraph 210 of the regulations.

EARLE, B. H., Assistant Surgeon. To proceed to certain points in Oregon for special temporary duty.

FOWLER, J. B., Acting Assistant Surgeon. Department letter of February 13, 1905, granting Acting Assistant Surgeon Fowler leave of absence for thirty days, revoked. April 7, 1905.

FRICKS, L. D., Passed Assistant Surgeon. Granted three days' leave of absence from April 3, 1905, under paragraph 191 of the regulations.

MCKAY, M., Pharmacist. To report to chairman of board for physical examination to determine his fitness for promotion to the grade of pharmacist of the first class.

MEAD, F. W., Surgeon. Granted leave of absence for six days from April 24th.

MULLAN, E. H., Assistant Surgeon. Relieved from duty at New York (Stapleton), N. Y., and directed to proceed to Ellis Island, N. Y., and report to Surgeon G. W. Stoner for duty.

SAFFORD, M. V., Acting Assistant Surgeon. To proceed to Portland, Maine, for special temporary duty.

STIMSON, A. M., Assistant Surgeon. Relieved from duty in the Hygienic Laboratory, and directed to proceed to Ellis Island, N. Y., and report to Surgeon G. W. Stoner for duty.

WATERS, M. H., Pharmacist. Granted leave of absence for fifteen days from April 12th.

WIGHTMAN, W. M., Assistant Surgeon. Granted leave of absence for three days from March 18, 1905, under paragraph 191 of the regulations.

Promotions.

Assistant Surgeon T. D. BERRY, commissioned (recess) as passed assistant surgeon, to rank as such from March 24th.

Assistant Surgeon A. J. McLAUGHLIN, commissioned (recess) as passed assistant surgeon, to rank as such from April 10th.

Appointment.

Dr. MARY A. ISRAEL appointed medical inspector for duty at Manila. P. I.

Boards Convened.

Board convened to meet at Washington, D. C., April 10, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Assistant Surgeon General W. J. PETTUS, chairman. Assistant Surgeon H. MCG. ROBERTSON, recorder.

Board convened to meet at Boston, Mass., April 12, 1905, for the physical examination of Pharmacist M. MCKAY to determine his fitness for promotion to the grade of pharmacist of the first class. Detail for the board—Surgeon R.

H. WOODWARD, chairman. Assistant Surgeon W. C. RUCKER. Acting Assistant Surgeon F. H. CLEAVES, recorder.

Board convened to meet at Washington, D. C., April 17, 1905, for the physical examination of officers of the Revenue Cutter Service. Detail for the board—Assistant Surgeon General W. J. PETTUS, chairman. Assistant Surgeon H. MCG. ROBERTSON, recorder.

Board convened to meet at San Francisco, Cal., April 20, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon W. G. STIMPSON, chairman. Passed Assistant Surgeon J. M. HOLT, recorder.

Board convened to meet at San Juan, Port Rico, April 24, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon W. W. KING, chairman. Acting Assistant Surgeon P. DELV. ATILES, recorder.

Board convened to meet at Port Townsend, Wash., April 24, 1905, for the physical examination of officers of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon J. H. OAKLEY, chairman. Passed Assistant Surgeon D. E. ROBINSON, recorder.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending April 15, 1905:

BANISTER, J. M., Major and Surgeon. On arrival at San Francisco, Cal., ordered to proceed to Fort Riley, Kans., for station.

BIRMINGHAM, H. P., Major and Surgeon. Relieved from duty as chief surgeon, Department of Texas, and ordered to Fort McPherson, Ga., for duty.

CARTER, W. E., Major and Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

COLLINS, C. C., First Lieutenant and Assistant Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

EASTMAN, W. R., First Lieutenant and Assistant Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

FORD, C. S., First Lieutenant and Assistant Surgeon. Ordered to report to commanding officer, Artillery District, Potomac, Fort Washington, Md., not later than May 1, 1905, for duty in connection with joint Army and Navy exercises.

GIRARD, A. C., Assistant Surgeon General and Brigadier General. Retired from active service at his own request, having attained the age of 62 years.

GRAY, W. W., Major and Surgeon. Relieved from duty at Fort McPherson, Ga., and ordered to Atlanta, Ga., for duty as chief surgeon, Department of the Gulf.

GREENLEAF, H. S., First Lieutenant and Assistant Surgeon. Ordered to report to commanding officer, Artillery District of Baltimore, Fort Howard, Md., for duty in connection with joint Army and Navy exercises not later than May 1, 1905.

HARTNETT, E. H., First Lieutenant and Assistant Surgeon. Ordered to report to commanding officer, Artillery District, Potomac, Fort Washington, Md., not later than May 1, 1905, for duty in connection with joint Army and Navy exercises.

HATHAWAY, L. M., First Lieutenant and Assistant Surgeon. Granted two months' leave of absence, to take effect when relieved from duty in Alaska.

HESS, L. T., First Lieutenant and Assistant Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

HUMPHREYS, H. G., First Lieutenant and Assistant Surgeon. Left Washington, D. C., on thirty days' leave of absence.

MANLY, C. J., Captain and Assistant Surgeon. Granted thirty days' leave of absence.

METCALFE, R. F., First Lieutenant and Assistant Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

MILLER, R. B., First Lieutenant and Assistant Surgeon. Ordered to report to commanding officer, Artillery District of Baltimore, Fort Howard, Md., for duty in connection with joint Army and Navy exercises not later than May 1, 1905.

MORRIS, E. R., First Lieutenant and Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

RAYMOND, H. I., First Lieutenant and Surgeon. On arrival at San Francisco, Cal., to proceed to Fort Riley, Kans., for station.

RICH, E. W., First Lieutenant and Assistant Surgeon. Relieved from duty in the Philippines Division, and ordered to proceed to San Francisco, Cal., and report to the Military Secretary for further orders.

ROCKHILL, E. P., First Lieutenant and Assistant Surgeon. Left Presidio of San Francisco, Cal., on thirty days' sick leave of absence.

STRAUB, PAUL F., Captain and Assistant Surgeon. Relieved from duty at Fort Leavenworth, Kans., and ordered to report in person to the Secretary of War for further orders.

WICKLINE, W. A., First Lieutenant and Assistant Surgeon. Left Washington, D. C., on twelve days' leave of absence.

WILSON, J. S., Captain and Assistant Surgeon. Ordered to report to commanding officer, Artillery District of Baltimore, Fort Howard, Md., for duty in connection with joint Army and Navy exercises not later than May 1, 1905.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending April 15, 1905:

BAKER, J. W., Surgeon, retired. Ordered to additional duty in performance of medical attendance of officers of the Navy and Marine Corps in the vicinity of Boston, Mass., not otherwise provided with medical attendance.

BENTON, F. L., Surgeon. Ordered from the Naval Recruiting Station, Philadelphia, Pa., for course of instruction at the Naval Museum of Hygiene and Medical School, Washington, D. C.

BISHOP, L. W., Passed Assistant Surgeon. Detached from the *Southery*, for course of instruction at the Naval Museum of Hygiene and Medical School, Washington, D. C.

CATHER, D., Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the Naval Training Station, Newport, R. I., with additional duty on the *Constellation*.

CORDEIRO, F. J. B., Surgeon. Detached from the *Solace* and ordered home to await orders.

FARWELL, W. O., Medical Director, retired. Ordered to the Naval Recruiting Station, Philadelphia, Pa.

FIELD, J. G., Surgeon. Detached from the *Bennington* and ordered to the *Solace*.

FISKE, C. N., Passed Assistant Surgeon. Relieved from duty at the Naval Hospital, Boston, Mass., and ordered to Washington, D. C., for course of instruction at the Naval Museum of Hygiene and Medical School.

FURLONG, F. M., Passed Assistant Surgeon. Ordered to report to the Surgeon General for special duty in the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

IDEN, J. H., Passed Assistant Surgeon. Detached from the Naval Hospital, Narragansett Bay, R. I., and ordered to Washington, D. C., for course of instruction at the Naval Museum of Hygiene and Medical School.

LEYS, J. F., Past Assistant Surgeon. Ordered to Washington, D. C., April 28th, for course of instruction at the Naval Museum of Hygiene and Medical School.

LUMSDEN, G. P., Surgeon. Detached from the *Minneapolis* and ordered to the *Olympia*.

MURPHY, J. A., Passed Assistant Surgeon. Detached from the Navy Yard, Washington, D. C., and ordered to Washington, D. C., for course of instruction at the Naval Museum of Hygiene and Medical School.

NORTON, O. D., Surgeon. Detached from the *Olympia* and ordered to the *Minneapolis*.

OHNESORG, K., Passed Assistant Surgeon. Detached from the *Topeka* and ordered to the Museum of Hygiene and Medical School, Washington, D. C., for course of instruction.

PECK, A. E., Passed Assistant Surgeon. Detached from the *Pensacola* and ordered to the *Bennington*.

PRYOR, J. C., Surgeon. Detached from the Naval Hospital, Narragansett Bay, R. I., and ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C., for course of instruction.

SHIFFERT, H. O., Passed Assistant Surgeon. Detached from the United States Revenue Steamer *Franklin* and ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C., for course of instruction.

SHIPP, E. M., Surgeon. Detached from the Naval Hospital, N. Y., and ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C., for course of instruction.

SMITH, G. T., Surgeon. Ordered to the *Maryland*.

STEEP, J., Passed Assistant Surgeon. Detached from the Training Station, Newport, R. I., and ordered to the *Topeka*.

STRINE, H. F., Assistant Surgeon. Detached from the *Helena* and ordered to the *Barry*.

Births, Marriages, and Deaths.

Born.

BRANCH.—In Fort Wood, N. Y., on Tuesday, March 28th, to Dr. Frederick D. Branch, United States Army, and Mrs. Branch, a son.

Married.

BLANCHARD—LOSER.—In Grand Rapids, Wisconsin, on Wednesday, April 5th, Dr. William Blanchard and Miss Harriet Loser.

DENNETT—WHEELER.—In Brooklyn, N. Y., on Wednesday, April 12th, Dr. Roger Dennett and Miss Agnes V. Wheeler.

FISHER—KANE.—In Washington, D. C., on Wednesday, April 5th, Dr. James Grant Fisher and Miss Amy Frothingham Kane.

GUNBY—PATTERSON.—In Philadelphia, on Thursday, April 6th, Dr. Hiram H. Gunby and Mrs. Sallie R. Patterson.

LANIER—STROUD.—In St. Louis, Missouri, on Saturday, April 1st, Dr. L. Herbert Lanier and Miss Annie Stroud.

SMITH—CANTERBURY.—In Brooklyn, Mass., on Monday, April 3rd, Dr. Winfield Smith and Miss Gertrude P. Canterbury.

VIRGIN—SORIA.—In New York, on Thursday, April 13th, Dr. Frederick Oakman Virgin and Miss Florence Soria.

Died.

BAKER.—In Davenport, Iowa, on Friday, April 7th, Dr. J. W. H. Baker, in the eighty-fifth year of his age.

GRANT.—In Clarksdale, Mississippi, on Thursday, April 6th, Dr. Hector M. Grant, in the eighty-fourth year of his age.

FULLILOVE.—In Boerne, Texas, on Tuesday, April 4th, Dr. T. W. Fullilove.

HULL.—In Maple Ridge, Michigan, on Tuesday, April 4th, Dr. Thomas A. Hull, in the fifty-sixth year of his age.

SCHROEDER.—In Bloomington, Illinois, on Friday, April 7th, Dr. Herman Schroeder, in the eighty-fifth year of his age.

SMALL.—In Lewiston, Maine, on Thursday, April 13th, Dr. William D. Small, in the forty-second year of his age.

WILLIAMS.—In Dunkirk, N. Y., on Monday, April 10th, Dr. Julien Taintor Williams, in the seventy-seventh year of his age.

WHOLE No. 1378.

Original Communications.

NEPHROPEXY, PRO AND CON.*

By A. ERNEST GALLANT, M. D.,

NEW YORK,

PROFESSOR OF GYNÆCOLOGY, NEW YORK SCHOOL OF CLINICAL
MEDICINE, ETC.

Nephropexy has been strenuously advocated on the ground that in many instances a prolapsed, movable kidney is productive of well marked symptoms which can only be relieved by this means, and this premise would hold good (a) if the kidney remained fixed; (b) if the kidney alone was at fault, and (c) if the other abdominal viscera were not distended, distorted, or dislocated.

Looking backward to 1885, we find that Glénard, under the heading *Entéroptosis*, was the first to recognize, clearly describe, and practically demonstrate that in nearly every case of prolapsed kidney a careful examination of the whole abdomen would detect more or less dislocation or dilatation of the stomach and intestines, with or without ectopy of the liver and spleen; and Glénard's findings have been confirmed by a host of careful observers.

Prolapsed, movable, replaceable kidney occurs frequently, often produces serious symptoms, can be easily palpated, certainly differentiated, and easily fixed, and when combined with postoperative rest in bed, quiet, and diet, the fixation brings about (for a time at least) most gratifying results, but only to end in a more discouraging relapse and return of all the previous symptoms whether the kidney adheres to its new attachment or not (Case V).

From clinical study we have learned to attribute certain symptoms to the kidney mobility; another group to gastrointestinal atony, prolapse, and distention; and others to the combined effects of both.

The symptoms due to prolapsed kidney are characterized by (a) their acuteness; (b) frequent recurrence; and (c) rapid subsidence after the kidney has been replaced.

The attacks designated *Diet's crises* come on with little warning, severe headache, nausea and vomiting, pain, and unilateral swelling along the loin, or general abdominal swelling, a sense of suffocation, an irresistible desire to loosen and remove all clothing and lie down, followed in a short time by relief and freedom from pain.

Hydronephrosis.—The most common and striking result of the traction and dragging of the prolapsed kidney on its ureteral pedicle is an acute angulation, causing retention of urine and dilatation of the kidney pelvis and the kidney itself, often to a serious degree (Case I). In many instances the woman patient is perfectly well on arising, but soon notices soreness and distention and pain along the loin and back, rapidly increasing to a "maddening" degree, culminating in an overmastering demand to loosen everything at the waist, and lie down for a short time, during which all the symptoms subside except some soreness along the loin; on arising she is compelled to urinate frequently and "as if she could never stop." These attacks are repeated from day to day or at longer intervals, but seldom produce nausea and vomiting, especially if the patient lies down soon after the attack begins, otherwise there will be added elevation of temperature, pulse, and respiration.

Jaundice.—Due to the traction of a prolapsed kidney on the cystic or common duct (Treves) jaundice not uncommonly follows confinement, and is often seen in multiparæ with lax, flabby, distended abdominal walls, coming on rather suddenly or gradually, with pain in the hypochondrium (gall bladder), radiating to the back at the lower end of the scapula, often agonizing and only relieved by morphine in liberal doses. Nausea and vomiting may persist for several days; the skin may be jaundiced as early as the first day or discoloration may not be noticeable for two or three days; it diminishes rapidly when the patient is placed in bed with the foot elevated; and reappears within a few hours if she is permitted to sit up without a snugly fitting abdominal support or binder. In every case seen by the writer, the right kidney has been found very

* Read before the Section in Surgery, New York Academy of Medicine.

much enlarged, forming a mass, its lower pole projecting two and a half to four inches below the chondral border, non-replaceable, tender on pressure, and easily to be mistaken for an enlarged gall bladder or lobe of the liver. On careful palpation and percussion, however, the free border of the liver can be distinguished from the rounded lower pole of the kidney, and the latter can be gradually replaced by careful massage and manipulation, thereby ruling out the possibility of gallstones, gastroduodenitis, etc. (Case III).

Hæmaturia caused by prolapsed kidney has been recorded by W. Cheyne and A. T. Cabot, and noted by the author as in Case II.

Appendicitis is without doubt an accompaniment of movable kidney, but experience teaches that inflamed appendices continue to cause pain, etc., after the kidney has been sutured, and that their removal is the only means of securing their owner from the danger of recurrent attacks.

The gastrointestinal group of symptoms, in contradistinction to those peculiar to mobile kidney, are notable in that they first appear during early womanhood, run a chronic course, and are seldom if ever relieved by the ordinary methods (Case V). The symptoms are those due to

(a) Chronic gastritis from dilatation or displacement of the stomach and colon; retention—fermentation, belching of gas, acid regurgitation, pain (epigastric, cardiac, left shoulder, and back), inconstant appetite, fear of certain food, and discomfort sooner or later after eating; each pointing to the stomach as the source of discomfort (Case IV).

(b) Chronic constipation. As the result of gastric atony, food, incompletely prepared, is discharged into the duodenum, which must bear the burden and finish, if may be, the preparation of food for absorption, an amount of work which it is not wholly competent to accomplish, and which leads to intestinal lethargy, manifested by irregular defecation, prolonged fecal retention, often constipation-diarrhoea, with chronic or recurrent mucous colitis and *autointoxication*, the most insidious because unappreciated form of intoxication—paralyzing all muscular, mental, and moral activity by an overmastering malaise. The skin is dry, mottled, or of a dirty brownish hue, the feet and hands are moist, the nose is oily, cracks and “fever blisters” occur on the lips, the breath is foul, the tongue coated, the urine scanty and high colored; there are frequent headaches, sleeplessness, irritability, and lack of power of concentration. The slender figure, slowness of hips, and underweight, each proclaims *malnutrition*.

OPERATION.

To operate or not to operate, that is the question; and one which cannot be answered by a hasty yes or no. The proximity of the solid viscera to the diaphragm, their up and down movement, the constant effect of gravity, the instability of the abdominal contents, variability of the hollow viscera, often associated with a lax abdominal wall, are features which must receive due consideration ere we solve so complex a matter and decide that we (a) must replace all prolapsed viscera; (b) must fix some; (c) may fix others; (d) must support all with or without fixation; and (e) must restore the muscular, mental, and moral equilibrium.

A. Visceral replacement can best be accomplished by placing the patient in bed, the foot being raised twelve inches from the floor, the body extended, and the head resting on a pillow. Gentle rubbing over the abdomen and kidney region will then relieve pain and “short-stop” the “crisis,” hydronephrotic distention will subside, the jaundiced skin clear up, the urine become free from pus, blood, and albumin, and, what is of equal importance, the diagnosis will be established; furthermore, confirmed, for when the patient sits up for a few hours, the pain, etc., will promptly return.

B. Fixation imperative. No surgeon will question the justifiability of suturing a prolapsed kidney after operations on the kidney or ureter for removal of calculi, drainage of a pus kidney, tuberculous kidney, or cystic kidney, or to fix a displaced kidney in its new location if producing symptoms of pyelitis or stricture of the ureter (El-liott), if albumin is present, or, as in Bramwell's case, pyloric stenosis and constriction of the duodenum by peritoneal bands are found. I have found it necessary to fix a large, heavy kidney lying below the waist line, in a woman over 50 years old, with a very lax, thin abdominal wall.

C. Fixation selective. The great mass of records, enforcing the view that a prolapsed kidney is an indication of Glénard's disease, enteroptosis, splanchnoptosis, call it what you will, especially in its association with dilated or prolapsed stomach, “must give us pause” ere we recommend nephropexy for those tormented with multiple ptoses.

The position of the kidney. Owing to the greater obliquity of the ribs in women, that organ (lower pole), when in place, lies above the twelfth rib posteriorly and above the costochondral border of the eighth rib in front, and cannot be palpated during quiet respiration, a fact which, to the writer's knowledge, has never been mentioned

in any anatomical textbook, all diagrams showing the relation of that organ being made from male subjects post mortem. This point assumes great importance when we endeavor to replace and suture the kidney, as in all methods so far devised at least one half of the kidney must lie below the twelfth rib, and be subject to constriction and compression by the corset and waistbands and dragging of the heavy clothing, as must also be the case when prolapsed just far enough to lie at the waist line, causing such pain that the woman cannot wear tight laced corsets or tighten her clothes around her waist. Furthermore, any kidney which has prolapsed to the waist line cannot be sutured to the loin *without pulling it down somewhat farther*, certainly a procedure not wholly free from danger. On the other hand, a kidney on or near the false pelvis but rarely causes acute symptoms, as the support from below prevents dragging on its pedicle. The ureter accommodates itself to the abnormal relations, and hydro-nephrosis but rarely intervenes, but retention of some urine in the inverted pelvis must occur and set up a pyelitis, which would justify nephropexy or, what I deem would be a more rational plan, *resection of the ureter and uniting the kidney pelvis to the ureter on a level with the pelvic brim*, and thereby reestablishing perfect drainage.

Gastroenterostomy, etc. There can be no question that in appropriate cases of stomach dilatation, plication of the stomach by the method of Bircher and others, or gastroenterostomy will afford relief; and the cases collected by Warren show that splenectomy is far less dangerous than attempts at fixing a wandering spleen. Carstens and others have successfully replaced and sutured the liver, which Einhorn has found so frequently to be mobile.

Suture of the lax recti abdominis has proved of benefit in the hands of Webster, Robinson, and Morris, who, "following German surgeons," has sutured the recti together in fifty-one cases.

But few operators are willing to follow Ingalls when he advises nephropexy, hepatopexy, splenopexy, gastropexy, fixation of the transverse colon, and reconstruction of the abdominal wall on one and the same patient, to say nothing of operations on the pelvic floor.

Kidney fixation, when the kidney remains fixed, will in some instances entirely relieve the attacks due to kidney mobility—Dietl's crises, hydronephrosis, hæmaturia, and jaundice—and drain the kidney pelvis of residual urine. In too many instances, however, the kidney does not "stay fixed," the wound area is painful, rarely hernia occurs, and a few patients die. Furthermore, the

chronic gastrointestinal syndromes (gastritis, constipation, malnutrition) and neurasthenic manifestations are not relieved, and the patient feels that she has been subjected to an operation which she would have been better off physically and financially without.

Mechanical measures in the treatment of movable kidney, such as belts, binders, bandages, and pads, have in a great majority of cases proved unsatisfactory, chiefly for the reason that they *compress, but do not support, or compress without replacement*, thereby doing additional injury to the already much abused intraabdominal viscera.

In order to meet the indications, since 1898 I have applied a new principle, first enunciated in 1901 (*Am. Journ. of Obstet.*, 1901, xliv, p. 1), whereby:

1. The prolapsed viscera are replaced by gravity, the patient lying in the dorsal posture with the hips elevated, and at the same time the viscera are manipulated toward the diaphragm.

Semiopisthotonos posture: Woman lying in bed, hips raised, causing viscera to gravitate toward the diaphragm when fastening corset for movable kidney, etc.

2. To support the replaced viscera the patient is fitted with a specially designed corset, made from measurements taken while lying upon her back, put on while in the semiopisthotonos posture, laced with two strings, introduced from above down, and adjusted by hooking from the lowest upward. When made and put on in this way the corset fits very tightly over the suprapubic area, and prevents the viscera from prolapsing, provides ample room at and above the waist line for the replaced stomach and colon, and the replaced kidney cannot be forced down while the corset is thus worn. In thin women the lower and back part of the corset must be padded inside to prevent undue pressure over the anterior superior spines. As soon as the corset is properly adjusted the wearer experiences a grateful sense of relief and support, Dietl's crises do not return, and the general condition gradually improves. The corset is not a "cure all," but it will

confirm the diagnosis, stop the attacks, and put the patient in a curable condition.

Rest cure. In some cases, owing to emaciation, frequent recurrence of the hydronephrosis, and predominance of neurasthenic symptoms, it has been found necessary to place patients in bed for four to eight weeks' "rest cure," and to fit the corset before permitting them to get up.

In some instances Rose's plaster strapping of the abdomen has been found of temporary use, especially while waiting for the corset, but the irritation of the plaster, and the difficulty and danger of wearing it *with an ordinary corset*, are objections which cannot be overcome.

From the considerable number of cases of Glénard's disease which I have seen, I select a few examples illustrating the views herein expressed.

CASE I.—(No. 1862, Roosevelt Hospital, O. P. D.) Glénard's disease (hydronephrosis). White girl, 11 years old. For about a year had suffered from attacks of pain in her back, both iliac regions, right hypochondriac and epigastric areas; belching, bloating, and indigestion; bowels moved daily; urination painful and excessive at times. Lower pole right kidney palpable, and replaceable; greater curvature of stomach on level with the umbilicus. Abdomen protuberant. Treatment: A specially fitted corset to support the prolapsed kidney and stomach, after replacement in the semiopisthotonos posture. This measure relieved all symptoms.

CASE II.—Hæmaturia due to prolapsed kidney. H. B., 42 years old, mother of two children. For the past week had been suffering from "misery" in the small of her back and along the right loin. Urinated frequently and noticed previous night that urine looked like blood. Examination of the right loin and hypochondrium disclosed a very tense mass, which on careful manipulation could be pushed upward behind the chondral border. The urine microscopically showed blood *thoroughly mixed* with the urine. Treatment: Rest in bed, and an alkaline diuretic. She was advised to elevate the foot of the bed, keep quiet, and rub the lump upward if it could be felt. Three days later she reported no return of the pain or blood since I had replaced the kidney. No recurrence during the past two years.

CASE III.—Postpuerperal Glénard's disease (jaundice). E. W., 22 years old, only child born five months before. Patient of another physician. Had not been well for four months; could not lie down on account of burning in her chest and right loin. Skin jaundiced for the past week. Half of the right kidney, very much enlarged, could be palpated below the chondral border, causing pain at the sternal junction of the fourth rib on the right side the same as she experienced during the attacks. Greater curvature of the stomach two inches below umbilicus. Treatment: Rose's plaster bandage. Eighteen days

later, the plaster having become loosened, she had a very severe attack, relieved by posture and morphine. Next day plaster reapplied. Five weeks later a special corset was put on and no recurrence has taken place during the past year.

CASE IV.—Gastrectasia. Dr. J. L. B., 65 years old, for the past twenty-five years had suffered from indigestion and intestinal colic, much worse for past four years. The attacks lasted about four days, and were associated with a dull constant pain, worse on movement, extending from the right hip to the back and occasionally to the umbilicus; not infrequently there was also a sort of "strangulation" of the muscles of the neck on the left side, with jerking. The application of Rose's plaster bandage soon relieved the pain on the right side; later, however, on account of irritation and inability to bathe while wearing it, the plaster was replaced by a special muslin bandage, and as the doctor expressed it "he could not believe such a change possible."

CASE V.—Nephroptosis, gastrectasia, not relieved by nephropexy. October 2, 1901. Mrs. F. E., 23 years old, one child, 13 months old. Complained of a feverish feeling in suprapubic region, and soreness in the sacral region, "like cords pulling;" frequent micturition; daily stool; good appetite, indigestion, occasional heartburn, hypogastric pain, no belching. Had lost weight for three years (127 to 107 pounds). Unable to wear a corset for the past year and a half. Only vegetarian diet. Right kidney opposite the anterior superior spine, replaceable under the ribs. Her former physician advised nephropexy. A ready made corset was put on in the dorsal decubitus and she was not heard from until May, 1904, when she complained of a stitch-like feeling in the right kidney region; felt weak and not good for anything. Greater curve stomach two and a half inches below umbilicus, succussion well marked. New corset adjusted; stomach lavage. November 25, 1904. Reported that since last seen she returned to her former physician and had the kidney sutured (August 29th) to the loin, the retroverted uterus to the abdominal wall; and was "just as bad as ever, in spite of operation and wearing an expensive abdominal belt." The ventrofixation caused pain by the drag of the uterus; the right kidney lay fixed three and a half inches below the chondral border, and was compressed by the waistbands; and the gastritis was as troublesome as of yore. Her financial condition now permitting she was fitted with a made to order corset and immediately experienced great relief.

CONCLUSIONS.

As the majority of clinicians now accept Glénard's theory that the movable kidney is merely an incident in the general ptosis, and symptoms referred to the kidney are much more likely to be the result of intestinal displacement, as is also the case in troubles caused by deformity or abnormal mobility of the spleen, liver, or kidney, and dilatation of the stomach, and as the symptoms due to kidney mobility (Dietl's crises, with hydro-

nephrosis, jaundice, or hæmaturia) can be differentiated by their acuteness, recurrence, and subsidence when the patient has been placed in the inclined dorsal position, and the kidney replaced; and *per contra*.

As the evidences of gastrointestinal displacement and disorders (gastritis, constipation, malnutrition, nervous instability, splashing sound, and distorted abdominal outline) are notable for their chronicity and rebelliousness to treatment; we deem that

1. Nephropexy is justifiable on a displaced kidney after operation thereon, involving it or its pelvis or ureter, or to relieve hydronephrosis or hæmaturia from a non-replaceable kidney.

2. Hepatopexy, splenectomy, gastroplication, gastrojejunostomy, and suture of the recti may be occasionally indicated.

3. The main obstacle to nephropexy in women lies in the greater obliquity of the lower ribs, which prevent suturing the kidney high enough to avoid harmful compression by the ordinary corset and waistbands.

4. Nephropexy is unjustifiable when, in order to place the sutures, it is necessary to drag the kidney farther down.

5. Nephropexy may relieve the symptoms due to kidney mobility, but in order to overcome those caused by the general ptoses it has been necessary to adopt a new principle, viz. (a) gravity replacement by the semipisthotos posture; (b) support of the replaced viscera by a corset made to order from measurements taken while the woman is lying down, laced with two strings, inserted from above down, put on while in the inclined dorsal posture, and fastened in front from below upward. By this method the viscera cannot prolapse while the corset is worn, and with this support nephropexy for replaceable kidney, *per se*, is but rarely indicated, multiple operations can be avoided, and the patient be placed under curable conditions.

60 WEST FIFTY-SIXTH STREET.

A New Hospital for Baltimore.—The North-western Hospital and Free Dispensary will soon be opened at 1147 North Fremont Avenue, Baltimore, where the executive board has secured temporary quarters and is fitting them for a waiting and drug room, a department for general medical treatment, one for the treatment of eye, ear, nose, and throat afflictions and one for gynecological diseases. It is the intention of the board to erect a building for the exclusive use of the dispensary, and it is probable that a general hospital will be included. Dr. William S. Gardiner is president of the association and Dr. Lee Cohen secretary and treasurer. The executive committee is composed of Dr. A. G. Barrett, Dr. Lee Cohen, and Dr. Albertus Cotton.

GALLSTONE DISEASE; REMOTE EFFECTS AND TREATMENT.*

By SAMUEL P. GERHARD, M. D.,

PHILADELPHIA.

To the efforts of the surgeon we owe much for a better knowledge and a clearer idea of the pathology of gallstone disease and from this we can deduce our view of the prognosis, treatment, and prevention of the remote effects.

The therapist has made very little progress in the application of remedies for this condition; therefore, the disease must be considered mostly from a surgical standpoint. Still there are many conditions and phases that call for medical treatment as palliative and cases where the surgeon would not feel justified in assuming the responsibility of an operation.

There is no doubt that many persons have gallstones and suffer no discomfort. Riedel states that in Germany ten per cent. of all adults have them, and that in five per cent. of this number they cause trouble. Thus in some persons the disease is latent, but trouble is liable to begin when the calculi escape from the gall bladder, excepting where the stones are so small that they pass out unobstructed and without inconvenience to the patient. However, in some cases where the stone is too large for the biliary ducts, great pain and obstruction of the channel supervene, and here is where the damage may begin. If, however, the spasm of the duct caused by the presence of the stone, which is practically a foreign body, is overcome and the flow of bile is strong enough to push the incarcerated stone along, it may pass out into the intestines, and, as far as that stone is concerned, the trouble is over; but there is no certainty how many more there may be in the gall bladder, how long they will remain there, and what their career may be after they pass out of the viscus. The attacks of biliary colic may then be frequent and indefinite. The gallstones of themselves never prove fatal and are perfectly harmless while they remain in the gall bladder, but there is no telling what accident may happen to any one on its journey through the ducts, and it is in place here to consider some of these accidents and their results.

If a calculus should become lodged in the neck of the gall bladder or in the cystic duct, the biliary fluid cannot pass in and out and the gall bladder becomes filled with a yellowish mucous mass, increasing in size. If infection is present cholecystitis comes on with its train of fatal effects, such as empyema and gangrene of the gall bladder, or a mild inflammatory condition may progress, and

* Read before the North Branch of the Philadelphia County Medical Society, December 8, 1904.

adhesions with the neighboring structures will be produced, causing repeated pains and gastrointestinal disturbances after the primary biliary attack has passed. The calculus may go back into the gall bladder, or it may escape from the cystic duct and pass down into the common duct and out into the duodenum; but its progress may be arrested in the common duct near the orifice, and if it remains there very long it is apt to grow larger from the continued precipitation of cholesterolin and completely close up the channel. Then on account of the anatomical relation of the biliary duct with the other organs we may have a chain of effects, especially if there is infection, which is most likely at this point. The calibre of the canal is decreased by the consequent inflammation and swelling, which still further fastens the stone and backs up the bile into the liver, causing cirrhosis, cholemia, and inflammation in the overworked kidneys. Adhesions as a result of the inflammatory process may occur between the neighboring and contagious structures, such as the omentum, stomach, and intestines, producing vague gastrointestinal symptoms.

As shown by Opie the pressure upon the head of the pancreas may cause pancreatitis, hemorrhagic pancreatitis, and pancreatic fat necrosis. A fistula into a neighboring organ through which the stone may escape into the stomach or bowel may be produced by suppuration. The danger of peritonitis cannot be overlooked at this point, nor the possibility of carcinoma of the gall bladder and passages.

After the gallstones have reached the gastrointestinal tract they usually pass out through the bowels without further trouble, but Schuyler has shown that they sometimes occlude the bowel from irritating the wall and cause reflex contraction and ulceration. This happens mostly at the ileocaecal valve and is rare. Yet with the great number of gallstones that remain quiet or are passed without any discomfort or dangerous symptoms it would not be wise to worry ourselves too much with the *remote effects*, but be always on our guard and watch for them so as to give timely warning for the proper surgical interference.

With our increased knowledge of the pathological processes involved in this condition, it is our duty to present a prognosis from a surgical standpoint, or where an operation has been advised. The best authorities and operators agree that in uncomplicated cases the mortality in operation is about three per cent., and this low percentage may be due mostly to the condition of the patient and not to the operation; but where there is infec-

tion, or the calculus has passed out of the gall bladder and become lodged in the duct, the mortality is higher and reaches sixteen per cent., so that we can infer that in those cases where the condition has not been allowed to progress too far and where an early operation is done the chances for recovery are very good, and doubtful only where surgical interference has been postponed too long. From this we see that it is the complicated cases that cause a high death rate from operation.

TREATMENT.

A few years ago the treatment of gallstone disease was entirely within the domain of internal medicine and the tendency of to-day is to put the disease under the head of surgery. This is due to the successful work of the surgeon who has given us an insight into the pathological condition as it exists in the living. Thus by a more exact diagnosis a better method of treatment can be outlined than was possible heretofore. As mentioned previously the medical treatment has made very little progress, and it seems that we have come to a point where we should study the prophylactic treatment, and we must admit that we know very little in this direction.

How to prevent the formation of gall stones is the mystery to be solved.

We may do something in the way of managing the habits and diet of our patients, advising the proper method of dressing, such as the avoidance of tight lacing or anything that may interfere with the natural flow of the bile, for it is admitted that bile stasis is one of the chief causes of the formation of calculi. Deep breathing should be encouraged so as to assist in clearing out the gall bladder.

When the calculi have once been formed there is no solvent yet found that will disintegrate them within the viscus. Many drugs have been lauded as solvents, such as sodium succinate, sodium oleate, and sodium glycolate, which are theoretically indicated because they increase the amount of bile salts, thereby preventing the precipitation of cholesterolin, which is the principal constituent of biliary calculi. But how can we get these drugs directly to the gall bladder without change? The experiment of dissolving calculi works splendidly in the test tube, but it is not possible to make a drug pass into a gall bladder against the natural outflow of its contents. We have heard much of the Carlsbad treatment which claims a great number of successful cures, but we can agree that if the same system was carried out at home we would obtain just as good results.

Many practitioners can mention numbers of

cases of success in biliary colic. Richardson submits a plan that may have some ground for the careful attention of those who have cases in charge. He advises the administration of sodium glycolate, which is a product of the liver and a bile salt, with a diet rich in fat, making a soap which he thinks may be absorbed through the intestinal wall and be carried by the circulation into the hepatic secretion and through this directly upon the calculi, thereby holding in solution the cholesterol and dissolving any precipitated cholesterol that may be present.

Olive oil was praised by many in the profession a few years ago and was thought to be a specific; even to-day the laity has great faith in its power to eliminate biliary calculi, but it has been demonstrated that it has no direct action and operates probably in a mechanical way, dilating and lubricating the channels as far as it can reach. It may act as a means of relieving the local catarrhal congestion of the neighboring intestine and clearing out the obstructing fecal matter, thereby allowing an imprisoned stone to pass along more easily.

The busy practitioner, however, is called upon in most cases to relieve a sudden biliary colic. It may be the first attack, the pain is intense and most agonizing and relief is desired at once. He is justified when he finds no signs of suppuration or tenderness or an enlarged gall bladder to give a hypodermic injection of morphine sufficiently large to relieve pain. A few whiffs of chloroform until the morphine acts, with hot fomentations over the region of the liver are very grateful. This may overcome the spasm of the duct and allow the stone to escape and relieve the most intense agony a body can suffer. It is remarkable how promptly this condition responds to morphine, but where you have a continuance of the colic after this medication, or a distended gall bladder, it should not be repeated and a search should be made for complications. The question then arises, Shall we operate?

I have recommended all my biliary colic patients to submit to operation, but in every instance they refused and declared they would rather take their chances of being relieved with medication than to suffer the loss of time and expense of an operation, and in every case their judgment was good, for in no case were there any remote effects.

The cases that require the most careful watching are those with vague symptoms without jaundice and only slight recurring pains over the region of the gall bladder; these are the cases that run on to suppuration and deceive the attendant.

The natural tendency of the gallstone is to pass

out by the nearest route, and this is through the biliary ducts, and so far as that is concerned we can trust nature to accomplish it. Therefore, in a well marked case of biliary colic we assist the process of nature with palliative treatment until the stone has safely passed beyond the danger of damage. But what of those calculi that remain? Now that one of the number has left the rest are more liable to follow by reason of the disturbance of their arrangement, and there will be an indefinite number of attacks of biliary colic. Shall we operate, or watch the course of each stone and ease the patient for the time being, hoping that they will all pass out safely? No one can tell what accident may befall the progress of any one of them; that there is danger in each stone there is no doubt, and for that reason the surgeon advises operation before there is trouble. But supposing they are all removed, what will prevent the formation of new calculi? Here lies the problem for the internist to solve.

The surgeon can remove them, but he cannot prevent the formation of new ones, excepting by the removal of the gall bladder, and even this will not prevent their recurrence in the biliary passages. However, we must not lose sight of the fact that wonderful strides have been made since 1878, when Marion Sims performed the first cholecystostomy, and the brilliant results that have been accomplished in the surgery of the gall bladder.

The operative treatment and technics have been so perfectly developed that we need have no fear to advise operation early in well marked cases of recurrent biliary colic, especially where there is the slightest sign of prolonged obstruction or inflammatory process present. Where the jaundice persists for more than a month it would undoubtedly be wise to cut in and drain the gall bladder. The operative technics of the biliary passages has not been developed so perfectly as that of the gall bladder, therefore it is urged by many to operate and remove the calculi as soon as recognized, and before they pass down into the passages where they cannot be so easily reached; hence the plea for early surgical interference.

The Carlsbad treatment is supposed to overcome this difficulty, but it seems to consist only in the ingestion of large quantities of water and the absorption of alkalies to encourage the production of bile salts. Means for the expulsion of the calculi are questionable, for it should be the duty of the physician and the aim of the treatment to prevent the disturbance of the calculi in the viscus and keep them quiet. From this we can see the fallacy of massage of the gall bladder,

for it is quite possible thus to produce a cholecystitis or force a stone down into the ducts and cause an obstruction.

Excessive purgation should not be permitted for the same reason, but the bowels should be regulated to move naturally with proper doses of sodium phosphate or sulphate or both in combination. The catarrhal condition in the duodenum about the orifice of the common duct after a stone has passed out or after an operation can be very nicely overcome by the administration of tincture of colocyth in doses of ten to twenty drops three times daily before meals.

The drinking of large quantities of alkaline water should be encouraged with a view of increasing the bile salts, and if it is true as some think that cholelithiasis is caused by cholecystitis or by an infection beginning in the bowel, then it would be our duty to administer intestinal antiseptics, but these two conditions may coexist and it would be too late to begin the antiseptics. The treatment then resolves itself into palliative and surgical, and we must use our good judgment and decide which to follow under the circumstances.

CONTRIBUTION TO THE PLASTIC SURGERY OF THE URETHRA.

By G. FRANK LYDSTON, M. D.,

CHICAGO,

PROFESSOR OF THE SURGICAL DISEASES OF THE GENITOURINARY ORGANS AND SYPHILOLOGY IN THE MEDICAL DEPARTMENT, ILLINOIS STATE UNIVERSITY; SURGEON TO SAINT MARY'S AND SAMARITAN HOSPITALS.

The plastic surgery of the urethra is in general one of the most unpromising fields of surgical endeavor. The conditions surrounding attempts to restore the normal continuity and calibre of the canal in cases of fistula, especially where there is marked loss of tissue, are such as peculiarly tend to prevent the accomplishment of asepsis, and to prevent the immediate union that is so essential to successful plastic operations in this region. Some of the lesser degrees of destruction of the urethral wall are more trying to the surgeon than others of much greater degree. In the extreme degrees of hypospadias and epispadias, for example, the conditions are often such as to render operation unwise. Again, where operations for these major defects of the urethra are performed, the patient is usually content with even a moderate degree of improvement, and of necessity must be reconciled to failure. In the slighter cases of hypospadias and urethral fistula the patient expects more; the closure of the canal seems easier of accomplishment, and the surgeon is likely to be tempted into simple and incomplete plastic pro-

cedures, which, *ab initio*, should not rationally be expected to succeed.

In the slighter forms of fistula a very important drawback to operation is the fact that, as plastic operations are ordinarily performed in this region, so much normal tissue is sacrificed that in case of failure, the patient is worse off than he was prior to the operation. It is nothing unusual to meet with cases in which a succession of operations have been performed by operators of a greater or less degree of competency, each of which operations has resulted in an aggravation of the urethral defect. Accumulating experience of this kind has led the profession in general to believe it inadvisable to operate upon the minor degrees of hypospadias, notwithstanding the great mental disquiet and physical discomfort incidental to the congenital defect.

After a considerable experience in the line of operative work under consideration, I feel justified in presenting to the profession the methods which I have found most satisfactory in my own cases.

The operation devised by my friend, Carl Beck, of New York, consisting of freeing the urethra and reattaching it at the extremity of the glans through a tunnel made in the latter, has a certain range of application, and has proved a very valuable method of relieving penile hypospadias. The shortening of the urethra, however, resulting from the operation and the occasional contraction of the glandular part of the new urethral canal are drawbacks of sufficient importance to render a successful substitute for the method welcome to the surgeon.

In that most frequent variety of hypospadias, in which the glandular portion of the urethra is represented by a cleft, and the congenitally defective meatus is situated just behind the base of the glans, Beck's operation seems rather too radical a procedure.

I have devised an exceedingly simple plastic operation for these cases, which has met with a large proportion of successes, and to which no exception can be taken on the ground of danger or loss of urethral tissue which shall enhance the deformity. The operation is done as follows:

When there is no cleft representing the roof of the urethra on the under surface of the glans a cleft is made as a preliminary step for the operation. This cleft is kept open so far as possible, so that when healed it will constitute the roof of the new canal, the formation of which is comprehended by the plastic operation. When healing of this cleft has been completed, two triangular surfaces are denuded, one upon either side, in the form of an isosceles triangle. The bases of these triangles are parallel with the proposed line of the urethra (Fig. 1). Between the bases of the triangles is left a narrow strip

FIG. 1.—The denuded surfaces, triangular in shape.

of intact epidermis, which represents the floor of the new urethra. The posterior portion of this intact strip consists of penile integument; the anterior of the roof of the cleft in the glans, which is to form the roof of the newly constructed portion of the canal.

The work may be done entirely under cocaine. The denudation having been completed, a very fine catgut suture is introduced, beginning at the centre on one or the other side at A. This is anchored, and a continuous suture made in such a manner that as the stitching proceeds the triangular surface is doubled upon itself at the centre. It is not always necessary to introduce one or more sutures at the outer edge of the triangular surfaces after the inner stitching is completed. The suturing of one side having been completed, the other side is stitched in a similar manner. (Fig. 2.)

FIG. 2.—Appearance after stitching.

By the procedure described the integument of the penis is brought forward in such a way that an intact epithelial floor of the new canal is provided, the floor itself consisting of a double layer of integument and subintegumentary structures, similar to that of the prepuce.

In cases in which circumcision has not been performed, the inferior surface of the base of the prepuce constitutes the integument involved in the flap from which the new floor of the urethra is constructed.

A catheter is introduced into the bladder and retained for about a week. I am by no means certain that in these minor cases the retained catheter is absolutely necessary, and I have suspected in certain cases in which primary union failed that the irritation of the catheter, acting as a foreign body, and followed secondarily by mild pus infection, was responsible for the failure. It has been my experience, however, that all is by no means necessarily lost in case of failure of primary union, for in several instances, as cicatrization proceeded, the flaps were drawn forward in such a way that what seemed likely to be only a partial success or possibly a complete failure proved an excellent result.

Small fistulae with a short tract in either the perineal or penile portions of the urethra may sometimes be dealt with in a very simple manner. The granulations lining the tract are first rubbed away with gauze wrapped about a probe by a rotary motion, or by a small curette. Hydrogen peroxide is freely used, so as to make the tract as nearly aseptic as possible. A longitudinal incision, the length of which necessarily varies with the location of the fistula, is made in the overlying tissues, the centre of which is made to correspond with the centre of the fistulous opening. The tissues are dissected away for a short distance upon either side of the incision, thus making a pocket.

FIG. 3.—The operation for small fistulae; dotted line shows pocket formed.

(Fig. 3, dotted line.) The fistulous tract is now carefully dissected out, the dissection just falling short of entering the urethra.

The cicatricial tissue and integument about the orifice of the fistula are next cut away. With a small torsion forceps the fistulous tract is twisted upon its axis, rope-wise, care being taken not to twist the tissues surrounding the fistulous tract to the extent of rupture, or to make it so short as to cause tension when it is stitched.

A suture is now passed from side to side, and made to transfix the pedicle, thus anchoring it in the wound. (Fig. 4.) The edges of the pocket formed by the preliminary incision are now brought together and stitched with horsehair or fine catgut. A collodion dressing is placed over the whole.

FIG. 4, a

FIG. 4, b.

Transfixing the pedicle.

It will be readily observed that in case of failure no tissues have been sacrificed. It is obvious, moreover, that the earlier the operation is done after the fistula has formed, the more promising the outlook. Where the simpler torsion method fails, and the penile fistula is small, the lateral buried flap method of Symanowski is an excellent one. It is most serviceable for the penile urethra, but in my experience is not so useful where there is a considerable loss of the urethral floor as the procedure that I will shortly describe.

It is a frequent experience after perineal operations involving the urethra that the wound is very slow in healing; not rarely a permanent fistula results. The latter may very often be avoided when the case shows stubbornness in healing by securing secondary union. The perineal wound is first denuded of granulations by rubbing vigorously with

gauze or by curettement, or both, as occasion may demand. The tract of the fistula is treated as already described in the torsion operation. A sound is introduced into the bladder, and double silkworm gut ligatures are introduced from side to side, care being taken to have the points of entrance and emergence of these sutures well away from the margins of the perineal opening. The larger the bight of the sutures, i.e., the more of the urethra included, the better the prospect of success. A small, hard roll of iodoform gauze is introduced beneath the loops of the sutures upon one side of the perinæum, the margins of the wound being brought firmly together by pressure upon the sides of the urethra, the fingers dipping well down into the perinæum. A second roll of gauze is placed within the pairs of ends of the sutures upon the opposite side. The ends are now tightly tied over the second roll of gauze. (Fig. 6.) The principle is the same as in the old

FIG. 5.—Method of securing secondary union.

fashioned quilled suture. The rolls of gauze are intended to act in lieu of the fingers, the pressure of which forms the best method of closely approximating the fistula. Fine catgut sutures may be introduced at the cutaneous margins of the fistula before the retaining sutures are tied over the gauze, if this procedure seems requisite. The number of retaining and of superficial sutures of necessity varies with the extent of the perineal opening which it is necessary to close.

Where there are no contraindications, it is well to introduce a catheter to be retained in the bladder, although this is by no means always necessary. In many cases secondary adhesion is perfect within a few days, although the patient is passing his urine *per vias naturales* at the usual intervals.

A successful result is usually obtained. Unless there is some special source of infection, failure is never complete, and a partial closure is obtained, which is often followed by prompt healing without any further surgical intervention. If it is necessary to suture again, this may, of course, be done.

It will, of course, be understood that the method just described is not applicable to long standing fistulae, the tracts of which have become callous and perhaps multiple.

In these cases a perineal section, with free division of all points of resistance to the urinary outflow, and the excision of the fistulous tracts, usually gives excellent results. Where necessary, the method of secondary suture which I have described may be undertaken during the healing of the perineal wound that has been made for the relief of obstruction and cure of the fistulae.

The operation of secondary suture of the perineal wound may usually be done under local anæsthesia, but even this simple operation is not always devoid of danger in nervous, irritable patients suffering from damaged kidneys. In two instances in my own experience acute suppression of urine and death from uræmia have resulted from the introduction of three or four sutures in the perinæum under cocaine. In both instances the apparently slight operation was performed several weeks after the original perineal section.

Fistulae of moderate or extreme size in the penile urethra may be closed in the following manner: As a preliminary to the plastic work any stricture or strictures in the urethra should be removed by dilatation or urethrotomy. The flap which is to be used in the construction of the new urethral floor may be formed either anteriorly or posteriorly to the fistula, according to the exigencies of the case. When the fistula is well forward toward the base of the glans, or located posteriorly in the vicinity of the scrotum, the posterior flap is usually best. When the fistula is located near the middle of the organ, there may be a slight choice in favor of the posterior flap, because of the fact that the circulation of the flap is less interfered with than when it is formed anteriorly. When there is very little loss of the urethral floor especially, the location of the flap, provided always it is longitudinal, is not important. In such cases the base of the flap is very broad relatively to its length, and the circulation is thereby made secure.

One advantage in the posterior flap, when the fistula is located near the scrotum, is that the scrotal tissues may be utilized for the new urethral floor, and these tissues being relatively thick, as compared with the penile integuments, the advantages thereby accruing are obvious. Should non-union occur when a thick scrotal flap is used, a partially successful result at least is liable to be secured, and subsequent plastic procedures are thereby rendered much simpler.

Where a scrotal flap is used, it may be necessary to destroy the hairs as a preliminary step.

Possibly I could do no better in describing the technics of the operation under consideration than to recount two typically illustrative cases.

CASE I.—Man, 45 years of age. History as follows: At the age of 3 years a small calculus escaped from the bladder and became lodged at the perinæo-scrotal junction. The physician who was called, unmindful of the disasters attendant upon external cutting operations into the penile urethra, cut directly down upon the stone and removed it. More or less suppurative and destruction of tissue resulted, and a fistula nearly an inch in length remained. The posterior commissure of this fistula was well down into the penoscrotal angle. Several attempts had been made to close this fistula by the ordinary methods

of freshening the edges, cutaneous flaps, and suture. These operations not only signally failed, but left behind more or less cicatricial tissue, which was destined to be an obstacle to further attempts at repair. Several attacks of gonorrhoea had been contracted during the patient's adult life.

I found upon examination three strictures, one in the middle portion of the penile urethra and another at each commissure of the fistula. The surface corresponding to the roof of that portion of the urethra involved in the fistula was formed of a smooth, level, cicatricial skin surface.

The preliminary steps of the operation consisted in cutting the strictures, followed by systematic dilatation. Simultaneously with the internal urethrotomy, a cleft was made with the knife in the tissues exposed by the fistula, with the intention of forming a continuation of the roof proper of the urethra. A fairly successful result was obtained from the operation upon the strictures, and a distinct sulcus continuous with the roof of the normal portion of the urethra was obtained.

After healing was complete, the patient was prepared for operation. A general anæsthetic was given. A semi-oval flap of penile integument, three quarters of an inch in width and an inch and a half in length, was marked out upon the skin of the penis anterior to the fistula. This was carefully denuded of epithelium down to a point corresponding with the anterior boundary of the fistula. (Fig. 6, A.)

A strip of intact epithelium a little less than a quarter of an inch in width was allowed to remain, extending from the anterior commissure of the fistula to within one quarter of an inch of the anterior extremity of the flap. (Fig. 6, B.) This was intended to form the epithelial surface of the new urethral floor that was to be constructed from the flap. A transverse incision was made at the base of the proposed flap from each side of the anterior commissure of the fistula to the outer border of the flap. Beginning just below this point, a pocket was made by dissecting the integument and subcutaneous connective tissue free from the underlying fascia. This pocket extended down into the scrotum, and extended to a point a little more than a quarter of an inch external to the border of the fistula. The posterior portion of this pocket involved the scrotum. The dimensions of the pocket are indicated by the dotted line. (Fig. 6, C.) The flap which had been outlined anteriorly was now dissected up carefully to the anterior commissure of the fistula, care being taken not to buttonhole it, until when drawn

down, it was continuous with the floor of the normal urethra without detaching it at any point at its base. This part of the operation obviously requires some delicacy of manipulation.

The flap having been detached, it was transfixed by two ligatures in its anterior extremity. Upon each end of the ligature was threaded a needle. (Fig. 6, D, shadow flap.) The flap was now drawn down, and the needles passed down to the bottom of the pocket and made to emerge, as indicated at A, Fig. 7. The flap was finally turned down over

Fig. 7.—The operation in Case 1. A, of the flap are needles emerging from bottom of pocket.

the fistulous opening and tucked into the scrotal pocket, this being furthered by tension upon the sutures. When it was snugly applied into the bottom of the pocket, the ligatures were tied. This procedure leaves the appearance shown in Fig. 7. The edges of the pouch being turned outward, the margins by the sides of the pocket by several superimposed layers of continuous fine catgut. The corners of the pocket now being trimmed off, the edges of the entire raw surface are brought together by continuous suture of catgut. This suture is best introduced in such a manner that something less than one quarter of an inch of raw surfaces is opposed. The whole is reinforced by a continuous suture at the skin margins.

It will be seen that a double layer of skin and cellular tissue is formed in this procedure, the whole being reinforced by a ridge of skin and subcutaneous tissue arranged in such a manner that there is a double line of suture between the flap and danger of infection. A perineal puncture was made and drainage established by a catheter of moderate size. The wound was sealed with iodoform gauze and collodion. The result in this case was ideal, and when last seen, some months after operation, conditions were still satisfactory.

CASE 2.—Man, 48 years of age, presented himself with the following history: He had been operated upon five different times for the closure of a defect in the urethral floor. He was not clear as to what the first operation was performed for, but I gleaned that it was probably an attempt to close a minor hypospadias. Each operation had resulted in failure, and what was worse, in the loss of a certain extent of the urethra.

On examination I found the floor of the entire urethra gone from the meatus to the scrotum. The pseudomeatus was located at the penoscrotal angle. At a point corresponding with the superior commissure of the normal meatus was a bridge of skin, evidently the remnants of the prepuce, about three

quarters of an inch in width. This was in a double layer, as is the case ordinarily in the prepuce. There was a slight chronic urethritis, in the discharge of which no gonococci could be found. The calibre of the portion of the urethra which was still intact was normal. Urinalysis showed a slight trace of albumin, but no casts. The excreted solids, and the quantity of urine were slightly subnormal. On account of the slight abnormality of the urine, and notwithstanding the extent of the urethral defect, I determined to use as a local anæsthetic a preparation used extensively by dentists, known as *acestoria*, which contains about one per cent. of cocaine in combination with essential oils and a very small dose of nitroglycerin. This preparation I have found safe and exceedingly reliable. The operation was as follows:

A posterior scrotal flap, three quarters of an inch in width and two and one half inches in length, was outlined. The superior extremity of this flap was rounded at each angle. This flap was now denuded, leaving a strip of intact epithelium about one eighth of an inch in width down its centre to within one half inch of the extremity. This flap began anteriorly a little in front of the posterior border of the defect in the urethral floor. The intact epithelium was continuous with the surface of the mucous membrane of the urethral floor. Beginning at the base of the proposed flap anteriorly, the penile integument and cellular tissue were dissected up on either side, forming a pocket. This dissection was carried into the preputial band already described by splitting the latter of the two layers. The pocket being completed, the flap was dissected up and brought forward, after transfixing its extremity with two double ligatures, as described in the previous operation. The needles were made to transfix the bottom of the pocket anteriorly in the preputial pouch already mentioned, and the ligatures tied. The edges of the pocket now being retracted upon either side, the thick flap was stitched down to the fascia propria of the penis by a continuous suture of fine catgut. This suture was inserted a little externally to the line of intact epithelium, stitching the urethral surface of the flap at this point to the edge of the quasimucous surface representing the urethral roof. This tier of sutures, it will be observed, is completely concealed by the flap. Two reinforcing lines of sutures, one above the other, were now superimposed, the triple suturing being made possible by the thickness of the scrotal flap. It will be noted that by this procedure leakage was opposed by three distinct lines of suture, the edges of the flap extending well out beyond the newly formed urethra. An attempt was now made to slide lateral flaps formed by the edges of the pocket toward the median line. This was found to be possible only for a small extent of the surface anteriorly, on account of the large amount of cicatricial tissue left by previous operation. On account of this impediment, a semilunar surface, the convexity of which was forward, was left upon the under surface, at the base of the penis, and at the point from which the scrotal flap had been removed. This was readily covered in by a second lateral flap, taken from the scrotum, which was twisted into position and sutured.

It will be seen that the new urethral floor was of

considerable thickness, the posterior portion of it being composed of two layers of scrotal tissue. I will state that it was not found necessary to remove any hairs from the posterior flap, from which the new urethral floor was made, the skin being largely cicatricial, the hairs having been destroyed by previous operations.

A small perineal puncture was made, and a No. 14 catheter introduced into the bladder for drainage.

The course of this case, so far as the success of the plastic operation was concerned, was ideal. It had, however, a very unfortunate ending. On the seventh day slight symptoms of uræmia developed, with a sudden diminution in the quantity of urine excreted, with considerable albumin and a few blood and numerous hyaline casts. The tube was removed, and the patient allowed to urinate *per vias naturales*. There was complete primary union, and although the patient urinated normally in greater or less amount from that time until the end, there was at no time a single drop of leakage, nor the slightest suppuration.

The patient died upon the eleventh day. Autopsy showed older interstitial nephritis, with recent acute inflammation, and hemorrhagic infarcts.

The outcome of this case was especially deplorable, in view of the fact that so far as shock was concerned the operation was a trifling one, and further because of the extreme care that had been taken to guard against just such an accident as occurred by employing local rather than general anesthesia.

From my experience in plastic surgery of the urethra, I have concluded that the average percentage of successes would be very much greater than it now is if perineal puncture and drainage were always instituted in plastic operations of any magnitude. The danger is not so much in the mere contact of the urine *per se*, but in the septic quality which it often possesses primarily or its destructive effect upon tissues and consequent interference with primary union when it remains in the interstices of wounds and there decomposes.

A frequent source of failure is the endeavor to get a large surface of intact epithelium for the formation of the new urethral floor in repairing large solutions of continuity. Where the surface of intact epithelium is broad, it is likely to become fixed in the outer margins of the wound in locations in which raw surface should be applied to raw surface. Obviously, when one of the surfaces brought in contact is covered with intact epithelium, no union can possibly occur. The necessity for a wide strip of intact epithelium in the urethral floor is greatly exaggerated. The narrowest possible strip of epithelium is amply sufficient, by virtue of the reproductive power of the cells of which it is composed. I learned this principle early in my surgical experience by observation of the growth of military skin grafts on chronic ulcers and granulating wound surfaces. A small military graft, for example, where it takes, will usually develop a round surface of epithelium of nearly if not quite the size of a silver dime. A very narrow strip of intact epithelium upon the floor of the urethra can be relied upon to form a new epithelial surface extending a variable distance from its border. The intact epithelial cells which were already normally adherent to the flap not only will not perish, but are very much more

likely to reproduce themselves and form a considerable surface of new epithelium than are miliary grafts.

I do not know of a more important point in the plastic surgery of the urethra than this. The method of repairing by a double layer of tissue the urethral defect, the flaps being taken from a location that insures considerable thickness, is as nearly ideal as it is possible to make a plastic operation in this region.

INFLAMMATION OF THE GLANDS OF BARTHOLIN.

By CHARLES C. MILLER, M. D.,

CHICAGO.

(Continued from page 802.)

TREATMENT.

Palliative treatment which has heretofore been recommended need not be considered. Soothing lotions, leeching, hot or cold applications, poultices, and other applications are of no value. Waiting from three days to a week for pus to form is neither logical or desirable in any case. If pus has not formed we have at least an accumulated fluid, which is responsible for the tension, and as the tension is the cause of the pain, relief of tension is the cardinal indication, and this should be accomplished only by the evacuation of the fluid causing it. This fluid has been present from the moment pain has manifested itself, and its evacuation is possible from the beginning. No interval of waiting and suffering is to be recommended.

These patients have almost without exception suffered a prolonged chronic infection, and I believe it is justifiable to recommend in all these cases the most radical plan of treatment, that is, the extirpation at once of the small tumor present. Such a plan is not imperative and will not be accepted in many cases, but it is no doubt the best way of disposing of a gland which menaces the woman's health and comfort in several ways, and renders her a source of danger to any with whom she may have sexual relations.

We will first consider the palliative treatment, where permission to extirpate is refused. The cyst of duct or gland should be emptied at once. In some cases this may be accomplished through the duct. The orifice of the duct should be found if possible. This will require a good light and a fine probe. At the junction of the posterior and lateral walls of the vaginal entrance the largest myrtiform caruncle will be found as a rule, and near its base will be found the opening of the duct. Sometimes several openings can be seen. Each of these should be tried in turn and if one is found which allows the passage of the probe

for a half inch it is most likely the duct of Bartholin. The dilated mucous follicles are as a rule not more than one half this length. If a very fine probe cannot be slipped into the cyst, we can sometimes overcome the resistance and facilitate the passage of the probe by forcibly distending the patulous portion of the duct with glycerin. This is accomplished with a piston syringe, which is supplied with a tip which will permit of entrance into the duct. After the glycerin injection we may again try the probing. Should we fail to insinuate the probe into the cystic accumulation, but pass it nearly to the tumor, it is justifiable, in the woman who is particularly afraid of any cutting, to attempt to force the probe into the cyst. To do this the tumor should be located and steadied by the disengaged hand. The force is then gradually increased to the probe, and it is directed directly toward the tumor. A fairly large probe may be used for this purpose, so that a somewhat free opening is secured. If the probe is forced into the cyst upon its withdrawal the contents will escape. Gentle pressure may be used to facilitate this. When the cyst is emptied, the duct is again likely to become occluded. One factor may act to cause an immediate closure, and this can be guarded against in some cases. The forcing of the duct will cause some laceration and bleeding into the duct. This cannot be avoided. The blood may clot and occlude the duct. The bleeding can be controlled by the injection of a one to five thousand solution of the active principle of the suprarenal glands. I have used for this purpose both the suprarenalin and the adrenalin solutions. Several drachms of the solution should be allowed to flow into and out of the cavity. That portion which remains in the cavity should not be disturbed. By the time its effect has worn off the tendency for bleeding to occur may have passed, and with no blood clots to assist in the blocking of the duct we may have it remaining patulous until the inflammation of the tissues about the gland has subsided, and then the strictured duct and diseased gland should be treated as I have previously described. Inflammation of the labia and perinæum, which may have developed before the patient was seen, may be treated by soothing applications to promote the disappearance of the inflammation so that treatment of the duct can be begun before it is again obstructed.

Where the opening of the duct cannot be found we must evacuate the accumulated secretions at once. This can be done from the inner side of the labium majus, but this site must never be selected for the incision in a case of this kind.

where no fistulous openings communicate with the inner surface of the labia or the vagina. Such an incision would drain virulent secretions too close to the vaginal orifice for safety. An exception might be made of the woman suffering from a purulent vaginitis. The incision should be made on the skin surface of the labium majus well away from the genital cleft. Where we merely intend to open the gland and drain off the secretions, cocaine injections will sufficiently obtund sensation to permit of the incision.

The tissues are steadied with one hand and the incision made directly down to the tumor. When the pus escapes, and the bleeding has been permitted to cease, a careful inspection of the parts should be made. The wall of the cyst can now usually be seen without difficulty. The margin of the cyst wall should be grasped with fine forceps, and after making traction it should be drawn out and separated somewhat, so that it can be drawn up near the skin margin on each side. It should now be stitched to the skin margin on each side by a single stitch. A ten per cent. cocaine solution should be used to mop out the cavity and this should be followed by pure carbolic solution. The excess of the carbolic should be wiped out and the cavity should be packed with sterile or antiseptic gauze. This gauze should be changed as often as soiled with pus. The irritation of the carbolic and the gauze will cause the formation of granulations, and when the cavity is allowed to heal from the bottom it will be thus obliterated. This will cut off the gland from the vaginal entrance, and it will almost invariably atrophy without difficulty. We should also make sure that the duct is obliterated so that a portion of it cannot remain as a nidus for the growth of the gonococcus. It is to be remembered that this treatment applies to those cases where the cyst has just appeared, and inflammatory symptoms have been present only for a few hours. Where the patient has not been seen until an inflammation of all the parts about the gland has developed cocaine injections will not permit of painless operations.

Thomas and Mundé in their work on gynecology recommended an operation from the mucous surface. It is in my opinion only applicable to those cases in which fistulae have formed on this surface and are imperfectly draining the cyst. In this operation an elliptical piece of the mucous membrane over the tumor is excised. The cyst is then partly emptied and a portion of its wall excised. They recommend that tincture of iodine be used to mop out the cavity and then that it be packed with iodoform gauze. I would warn

against the iodine as it will cause intense burning pain for some hours after the operation. I have had such an experience with it in two operations of this kind and from this experience in both instances advise against its use.

Hart and Barbour recommended opening these cysts with the cautery, but the only advantage of the cautery is that primary union of the cut is prevented. We can secure the same result by keeping the cavity packed for a few days after incising it.

The injection of irritating solutions such as the ten per cent. zinc chloride solution after aspiration of the cavity has been recommended, but should no longer be practised in the light of present surgical methods. It will be followed in all probability by continuation of the painful symptoms, as these strong irritating injections are liable to augment the inflammation, and result in the rapid throwing out of inflammatory material.

THE ACTUAL CAUTERY IN THE RADICAL TREATMENT OF SUPPURATING GLANDS.

Where the gland is enlarged and inflamed and there is a retention cyst filled with pus and mucus, we can treat the condition by freely opening the cyst; then, carrying our finger into the cavity, dilate the various subdivisions of the cavity so that all become accessible, and then with the actual cautery we can destroy all secreting surfaces and treat the cavity by gauze packing.

In doing this operation we must decide as to the site of our incision. If we place it well down in the interval between the labia minus and majus, it will be effectively hidden after healing has occurred, but this incision has several disadvantages.

If suppuration is quite free, there is danger of reinfecting the vagina or even the urethra after the operation, and this may prove anything but a simple matter. The woman may have previously escaped a pelvic inflammation, and following the reinfection we may find it ascending to the uterus, tubes, and ovaries and irreparable damage may be the consequence.

Following this operation packing must be used and healing must occur after the development of granulations, and in this way a considerable scarring may occur at this point, and it is possible that this scar will be tender so that sexual relations are rendered painful. I have used the incision several times, but have never noted any such untoward consequence as a subsequent tender scar. It is mentioned by other writers as a possible untoward consequence.

The best incision, in my opinion, is made well out of the skin surface of the labia majora and

well back toward the perinæum and encroaching upon this latter structure.

It will be a surprise to the man who operates upon these cases for the first time to see how far backward and how close to the rectum the incision should extend to permit of perfect drainage from the cavity which he makes or finds after opening or extirpating this gland. Therefore at first it is well to begin the incision at least no farther forward than on a level with the posterior vaginal wall.

If a large cystic tumor exists, the knife will very quickly enter the cavity of the cyst. The opening should be made large enough to permit of the entrance of the index finger of the operator. The finger is carried in and a number of intervening *sæpta* will be found which subdivide the cavity into a number of compartments. These should all be explored to their limits by the finger of the operator, and the *sæpta* broken down where this exploration is prevented.

The finger should now be carried backward, and then with scissors or scalpel the incision should be enlarged posteriorly until the limit of the cavity is reached. This enlarging of the incision is of importance as the patient will lie upon her back after the operation and it will thus allow of perfect drainage. In some cases it will be necessary to lengthen the incision anteriorly to give perfect access to the entire secreting surface of the gland, but in many this will not be required.

If forceps are applied to the lips of the wound and good retraction is secured, the gland surface will lie exposed before the operator. It will be found to be quite irregular, as a rule, and it is my custom to trim away all irregular glandular masses which project into the cavity before using the actual cautery. This is accomplished with scissors and causes some bleeding, which is checked by the cautery.

The cautery is to be used freely and the operator must make sure that all portions of the cavity receive a thorough application of the cautery while it is hot. The Paquelin cautery is cooled very quickly when it is sunk into oozing tissues.

After all surfaces have been treated with the cautery the cavity should be mopped out with gauze, and then packed with either the sterile gauze or gauze impregnated with iodoform. In these cases I prefer the iodoform gauze.

These patients are put to bed after the operation, and the packing is changed daily for three days. After this time only enough gauze is inserted into the cavity to hold the posterior portion of the skin incision open until healing by

union of granulations has occurred. The cavity is filled more or less with granulations.

Where the incision has been carried well forward and it has been necessary to make it rather long to allow of perfect access to all the gland surface, the anterior portion of the incision can be closed by sutures, and scarring is thus minimized.

Where there is but a slight reaction, and the parts do not become much inflamed, the patient may be allowed to be up and about in a day or two after the operation, but where the reaction is at all severe the patient will feel but little inclination to leave the recumbent posture.

The time of healing varies in these cases. In some free suppuration develops: In all these cases the suppuration is checked most quickly in my own experience with irrigations with a one to five thousand solution of formalin.

The irrigations of formalin are used from one to three times in the twenty-four hours, when the suppuration is free, and the iodoform gauze packing kept up until it is checked. As soon as suppuration is checked, the cavity should not be dilated by packing, the walls should be allowed to fall together and only a very small strip of gauze used to hold open the skin incision.

The scarring following this operation is not objectionable as a rule, as it is not great and the scar is so far back as to be quite out of sight of the patient. The parts are also more or less covered with hair at this point, and when such grows out it further serves to render the scar less conspicuous.

THE REMOVAL OF THE SLIGHTLY ENLARGED GLAND
IN ALL CASES WHERE THE OPPOSITE SIDE IS TO BE
OPERATED UPON FOR A FREELY SUPPURATING
INFLAMMATION OF THE GLAND.

Whenever a gland is to be operated upon in which free suppuration has caused the development of a distinct tumor, the operator should always carefully palpate the opposite side, and if it is possible to feel the gland on that side, an incision should be made and it removed before the operation upon the suppurating gland is attempted. Some may object to this suggestion on first thought, but it is not to be forgotten that if the gland is palpable it is infected. Trouble to the patient may not come for some time, but the gland is a menace to her and to any with whom she should have sexual relations, so that its removal will be more of an advantage than otherwise and the wound made will heal long before that of the opposite side.

It is important to operate on one of these glands by

first, as after the operation upon the suppurating gland infection is much more likely to occur. The gland should not be considered uninfected.

Operation upon these glands is very simple. The gland is steadied between the fingers of one hand, and with a scalpel it is exposed. Now in many more instances than the beginner would suspect, the gland will be found to contain considerable secretion and pus, so that it should be handled carefully and should not be cut into if possible.

The dissection should be made to the outer side and behind before the portion toward the vagina is separated, and should a pearly smooth surface come into view, it should be kept well away from, as it is probably a dilated duct, which should be severed last.

Should the gland be removed without soiling the wound with secretions or pus, it is advisable simply to close the wound by one or two stitches, and then to seal the skin surface by several coats of collodion before attacking the opposite side. If the gland contains pus, or secretions mixed with pus, and they escape into the wound, it is advisable to pack the cavity with iodoform gauze, after a silkworm gut suture or two have been inserted. These sutures are not to be tied until we have controlled any suppuration which may develop.

Sometimes there will be quite a persistent oozing from the bottom of the cavity, or anteriorly, as a result of injury of numerous small veins. This condition is controlled with difficulty by hot irrigations, and as there is no particular bleeding point we cannot catch it with hæmostats and twist or tie it. These bleeding surfaces are controlled without the least difficulty, if a mattress suture of fine catgut is carried beneath the surface which is bleeding, and tied. In tying such a suture it is not necessary to tie at all tightly. The suture is grasped and tied gently with a single knot. An assistant now mops out the cavity with gauze, and if the suture is tight enough no further bleeding occurs from this point. Should the oozing persist the suture is tightened slightly, and the parts are dried again by the assistant. As soon as the oozing is controlled, a second knot is made in the gut and it is cut short. These sutures I have never found to cause any harm, even in infected cases where they have been carried rather deeply into the surrounding parts.

(To be concluded.)

Dr. G. B. Tanguay, of Laval University, Montreal, has been appointed examiner in pathology for the College of Physicians and Surgeons of the Province of Quebec.

THE PROBLEM OF EXTERMINATING MOSQUITOES; DISCOVERY OF IN-ACCESSIBLE BREEDING PLACES.

By H. A. EBERLE, M. D.,

GREENSBORO, S. C.,

LATE CAPTAIN AND ASSISTANT SURGEON, UNITED STATES VOLUNTEERS.

During a term of service spent at various army posts in the Philippine Islands in the capacity of sanitary officer and assistant surgeon United States Army, the subject of mosquito destruction and propagation became an interesting study to the writer.

At the army post of Jolo, Jolo Island, P. I., from one to two battalions of soldiers were stationed, and from the number of admissions into the hospital of soldiers suffering from malarial and dengue fevers caused by the bites of mosquitoes, the subject of exterminating the pests became an important one.

The walled city of Jolo has well paved streets and is well drained with open cemented sewers. The streets were swept twice daily, the yards and alleys cleaned, and all accumulation from kitchens and back yards were daily carted away. No pools of water were allowed to exist and no grass or weeds were permitted to grow in the public gardens.

Every receptacle capable of holding water was removed and efforts were made to do away with all suspicious breeding places where mosquitoes might propagate.

Yet with all these precautions to prevent their propagation there were myriads of mosquitoes, and the important question arose as to where they came from. It chanced one morning, as the writer hitched his horse to a papaya tree, he observed a knot hole on the trunk of the tree full of water, and on close observation it was found that the water was alive with countless mosquito larvæ (grigglers). This interesting discovery hinted that the numberless knot holes in the trees might be a source from which the bothersome pests originated.

To test the suspicion the writer mounted his horse and went to the hospital, where he procured a wide mouthed bottle and a spoon, then returned to the papaya tree and carefully transferred the contents of the knot hole (consisting of about four ounces of water, sediment of decayed leaves, and dirt) to the bottle. Taking this at once to the laboratory the contents were emptied into a gallon glass jar filled with distilled water, and covered over with two layers of mosquito bar.

Next morning, on examining the jar, there

could be seen myriads of mosquito larvæ in all stages of development. Pupæ were numerous, and twenty-five fully fledged mosquitoes perched on bits of cork as a resting place were noticed. These newly fledged mosquitoes were collected, chloroformed, and classified with the aid of a powerful lens. Daily, during the next ten days, a new crop of mosquitoes was collected from the jar, and in all five hundred were hatched from the contents of one knot hole.

Three species of mosquitoes were noted, and several varieties found of each of the species. *Culex*, or the common mosquito, predominated; next in number was *Stegomyia fasciata*, or the yellow fever mosquito, and *Anopheles*, or the malaria producing variety came next.

The second discovery in regard to the breeding places of mosquitoes came about in the following manner: One morning while on his way to attend a sick call at the hospital the writer noticed a branch which had recently fallen from a cocoanut tree and on examining it found, where the stem becomes broad and concave at its point of attachment to the tree, a mass of undisturbed black sediment. This was carefully gathered in a clean paper, and taken to the hospital laboratory, where it was placed in a jar of distilled water. The next day newly hatched mosquito larvæ could be seen wriggling their way to the surface of the water to breathe. Daily examinations were made and within ten days many fully developed mosquitoes were collected and classified.

The writer's observations were extended to the banana tree with the result that in the sulci which always were found to contain water, mosquito larvæ could be found and subsequently developed into lively mosquitoes.

A great majority of tropical trees are of the palm variety, having at the joining of each leaf with the tree sulci or concave depressions where-in mosquitoes may breed and hatch safe from disturbance, the only possible means of eradicating them being by the complete destruction of the palm crop. In view of the impossibility of destroying a country's most profitable crop what becomes of the mosquito control question? Must diseases like yellow fever, malaria, filaria, and dengue always prevail in tropical countries?

Among the laity there is a widespread though erroneous belief that the mosquito bite of itself causes the disease and that the infection is from the mosquito *per se*. This is no doubt due to hearing the various species of mosquitoes classed as "malarial mosquito," "yellow fever mosquito," etc., but the fact is that the mosquito is merely the transferring agent and must become infected

itself before it can inoculate a human being with disease. Some species are capable by their organism of carrying one disease, while others are limited to an entirely different one, each species spreading its own peculiar variety of infection. The bite of a mosquito of any species is innocuous, however, unless it has itself been previously infected.

In view of this it is the opinion of the writer, who has done much sanitary work both in the Philippines and Porto Rico, that the only method of preventing the spread of transferable diseases is to teach the people to observe the strictest sanitation, both of their persons and surroundings. Not only yellow fever, but many other transferable diseases are filth diseases and their micro-organisms spring no doubt *de novo* from filth causes, but the contagion must be transferred to us, who are incapable of receiving the infection direct from the filth, through the mosquito which is so infected.

Hence if absolute sanitation was observed there would be no primary infecting of the mosquito, and hence no infection carried by their bites.

The sanitary officer has a burdensome task to perform, yet one that will show the most brilliant results in stamping out transferable diseases by teaching the people to observe the simple rules of sanitation.

218 SUMMIT AVENUE.

Cerebrospinal Meningitis.—Coincident with the appointment by the department of health of a commission of eminent physicians for the investigation of cerebrospinal meningitis, a corps of medical inspectors, five in number, was organized and assigned to the sanitary supervision of the disease in the borough of Manhattan. These physicians attend to the isolation and quarantine of patients at their homes, order the necessary disinfection of premises and bedding in patients who have recovered, died, or been removed to a hospital, and report as to the sanitary condition of the premises and any violations of the sanitary code. They have had the opportunity of observing a large number of cases of the disease, and their services are at the disposal of any physician who may wish assistance in the diagnosis of suspected cases. A physician trained in such work has been assigned to the performance of lumbar puncture at the request of the attending physician. The department of health advises that lumbar puncture be done in all cases where practicable; both as an aid to diagnosis, and in order to obtain more material for bacteriological study and consequent advancement in our knowledge of the disease. Requests for the services of a physician for diagnosis, disinfection, or lumbar puncture should be made direct to the Department of Health, Fifty-fifth Street and Sixth Avenue (telephone, 1204 Columbus), where they will receive prompt attention.

PRIMARY EPITHELIOMA OF THE UVULA, WITH REPORT OF A CASE WHERE RECURRENCE TOOK PLACE AFTER TWO OPERATIONS FOR RE- MOVAL.*

By HARMON SMITH, M. D.,

NEW YORK,

ASSISTANT SURGEON MANHATTAN EYE, EAR, AND THROAT
HOSPITAL.

The infrequency of epithelioma in this locality warrants a few remarks upon this subject in addition to the mere recital of the features of this particular case. Nearly all authorities are agreed that smoking may possibly enter as a causative factor, and in nearly every instance the subject has been a male. Heredity has apparently played no important part in the etiology of the disease. Another fact at variance with the customary symptoms of epithelioma, is the relative early age at which the growth appears. McCaw¹ reports a case of epithelioma in a woman aged 37 years. Lenox Browne a case aged 48 years,² and the patient whose case I now report is 51 years old.

The adjacent glands have not been frequently involved, showing that the growth has not spread by the lymphatics, except when the tonsils and lateral wall of the pharynx have been implicated. This should lead us to the definite conclusion that the growth is one involving the muciparous glands of the soft palate, and consequently of slower growth than one extending through the lymph channels. This conclusion is verified by all the pathological reports, in the light of which the operator has more reason to believe that an operation of sufficient magnitude would entirely circumscribe an epithelioma in this location and thoroughly eradicate it. In both Downie's³ and Lennox Browne's cases the operation was a success within a period of seventeen months in the former, and nine months in the latter. In a case reported by S. Oppenheimer, the age of the patient (81 years) and extensive involvement of adjacent structures excluded the feasibility of operation. In this case the cervical glands were enlarged, but I presume that this occurred only after the neighboring structures were included in the growth. Here the employment of the x ray or radium might have given us important data as to their effectiveness. In the case of McCaw's the method pursued was of such combination of surgical procedure and x ray application that a definite conclusion as to the effectiveness of either is wanting. In his case the family seem to have had some

malignant tendencies, as one sister died from an operation for the removal of an abdominal tumor, and a second sister living is suffering from an obscure abdominal growth.

The partial excision by the cautery knife of the uvula and part of the soft palate in the first instance, together with x ray treatment in the interim, possibly reduced the rapid extension of the tumor; while the second removal with the same agent may have entirely eradicated it. However, the time is too short to form any definite opinion relative to the merits of either procedure. I must confess some skepticism as to the efficiency of the x ray in the cure of malignant growths. I have seen pain reduced and discharge stopped, but either a deeper penetration of the tumor resulted or a metastasis was produced. The invariable symptom complained of in all these cases has been irritation in the throat, and not pain. The inconsequent innervation of this part would account for the absence of pain, while the irritation is possibly due to the mass scratching the pharynx during the act of deglutition. I believe the only rational way of treating these cases is thorough extirpation with scissors or the cautery knife. I shall give subsequent reports upon this case, and should the last operation prove inefficient, I will try the x ray for a time sufficient to note whether there is improvement or not, and then use radium. Should neither of these remedy the case, I shall have recourse to a new light ray advocated by⁴ Dr. Piffard.

From the examination of 12,000 cases of cancer, the committee for the investigation of cancer in Germany found the relative frequency of cancer of the nose and throat in males, as compared to its frequency in females, to be as follows in 1,000 cancer patients:

	Males.	Females.
Nose	13	17
Lips	77	8
Mouth	13	2
Tongue	21	3
Larynx	17	2

This bears out the statement already made of the greater proportion of cases existing in males.

PATIENT.

W. I., aged 51 years, a cooper by trade, was received at the clinic of the Manhattan Eye and Ear Hospital, June 13, 1904, with a history of difficulty in swallowing and dryness of throat for nearly one year. All the discomfort was referred to the larynx. Denied any specific or tuberculous conditions, and had been on iodides a sufficiently long time to exclude syphilis. He had been a great pipe smoker.

Examination revealed an angry strawberry-looking mass on the uvula, with induration extending outward on the soft palate of the right side for half an inch, some erosion of the surface, and creamy exudate thereon. No glandular involvement on the

⁴ Med. News, December 3, 1904.

right side, but a very large, hard gland was felt in the opposite submaxillary region. Patient had some pain in the right ear and was emaciated and cachectic. Could not sleep, eat, or work. The clinical diagnosis was epithelioma, and arrangements were made for immediate operation, likewise for the examination of a frozen section to determine the extent of the substance to be removed.

The patient was anesthetized June 20th and a piece of the growth was removed for the frozen section examination, the result of which proved the tumor to be an epithelioma. A wide incision was then made with scissors around the mass on both sides, including a considerable portion of the soft palate. Some difficulty was encountered in controlling the hemorrhage, as the soft palate through which the incision was made was very much indurated and was at least half an inch thick. The hemorrhage was finally controlled by tying off sections of the palate around the line of incision. Such induration existed that it was impossible to coaptate the edges of the wound, consequently a large U shaped opening was left.

The tumor was submitted to a further microscopical examination by the pathologist of the hospital, Dr. Zabriskie, who confirmed the former diagnosis. The vascular changes were those of chronic arteritis with dilatation.

Recovery was rapid and satisfactory. The patient left the hospital July 1st. The highest temperature during the entire time was 101° F.

I saw the patient once a week after this, and noted that he had gained in weight (15 pounds). He resumed work and seemed to be getting well. On July 20th, however, I noticed a slight redness and induration on the right border of the wound which suggested a recurrence. After a week's consideration, during which time the appearance became more conclusive, another operation was performed in which the lower and right border of the palate was removed as far as the right pharyngeal pillars. The piece was submitted to the pathologist at the hospital, and the report is of sufficient interest to warrant its being given in full.

"The sections show the principal mass of the tumor lying on vascular tissue containing glands which are undergoing atrophy. The tumor consists of epithelial cells lying in whorls and irregularly scattered about, with no supporting intercellular substance. As there is a distinct layer of muscular tissue undergoing this which shows only a very moderate degree of inflammatory reaction, I should say that the mass had been pretty thoroughly eradicated, at least judging from that portion submitted for examination. This, however, is no positive indication that it will not recur."

The patient was able to leave the hospital on the next day after the operation and I removed the sutures put in for controlling the hemorrhage one day later. The patient was still held under observation and seen once a week. He gained altogether 30 pounds and has felt well since.

Three months later, about November 1st, a small granular tumor, of the size of an apple seed, appeared at the upper angle of the wound, and was sensitive to the touch, pain being referred to the larynx. This tumor continued to grow until it was the size of a

pea, when it was advised to perform another operation in the endeavor to completely eradicate the growth. It was also deemed advisable to remove the enlarged gland from the left submaxillary region. The patient was again operated upon December 2nd, when everything at all suspicious on the right side was taken out, including part of the pharyngeal pillar. The gland of the opposite side was removed and was found to be attached to the submaxillary, a part of which was likewise removed. Hemorrhage was controlled by clamps, and after their removal a combination of compound tincture of benzoin and iodoform applied.

The patient left the hospital on December 7th, and the wound healed without incident. There was some speculation as to the character of the glandular involvement, and I give herewith the pathological report of Dr. Jonathan Wright upon the gland removed, likewise his report upon the tissue removed, which to observation appeared to be a recurrence of the epithelial growth:

"On examining microscopically sections of the submaxillary tumor it is evident at once that we have here a racemose gland and that it is much altered by disease. There is great increase in the fibrous framework, but through the main structures I am unable to find any invading epithelium either glandular or heterogenetic.

"The glandular epithelium itself is so greatly proliferated and degenerated in places apparently quite mucoid in character, that it is impossible to be sure that heterogenetic epithelium has not invaded it. I am inclined to think, however, that this is not the case in view of the fact that I can discover no epithelium in the lymph channels, but that we have here a chronically inflamed submaxillary gland, which from the history has existed for a long time, and so far as these sections go, presents no evidence of extraneous infiltration. Some of the arterioles in the stroma present also a mucoid degeneration of their coats, and this in places under the low power gives rise to the suspicion of an epithelial nest. Without a complete examination of all the sections of the gland I am unable positively to assert the non-existence of such a focus.

"*Microscopical Examination of Piece Removed from Soft Palate.*—There is a small area in this epithelium which takes a lighter stain than the rest and at two or three spots there are some abnormally large and degenerate epithelial cells. There is, however, no satisfactory evidence that the epithelium is infiltrating the stroma, or that this hyperplasia is really malignant."

At this date, some five months after the last operation, the patient is in fine health, and no evidences are apparent of the recurrence of the growth.

44 WEST FORTY-NINTH STREET.

The Oneida County, N. Y., Medical Society elected the following officers on April 11th: President, Dr. Herbert G. Jones, of Utica; vice-president, Dr. C. A. Frost, of Rome; secretary, Dr. F. H. Brewer, of Utica; treasurer, Dr. E. D. Fuller, of Utica; librarian, Dr. Smith Baker, of Utica.

INFECTION THROUGH THE TONSILS.

By WILLIS S. ANDERSON, M. D.,

DETROIT, MICH.,

LARYNGOLOGIST, HARPER HOSPITAL POLYCLINIC.

The tonsils, ubiquitous in medical literature, have received much consideration during the past decade, and it would seem from the voluminous literature devoted to these structures that little could be added that is new. The vast amount of literature and the widely differing opinions expressed by various observers as to the importance of these structures, both in normal and pathological conditions, show that there are still many points that need to be settled. Even their function has elicited much discussion. It is now generally accepted that the tonsils are lymphoid in character, and have a function similar to that of the lymphoid tissue in other parts of the body.

In various portions of the body Manfredi has shown that the lymph nodes protect in three ways: 1, By filtration; 2, by weakening the microorganisms that reach them; 3, by the whole organism obtaining a greater or less degree of immunity while the first two processes are in operation. The tonsils, which resemble the lymph nodes, probably exert an influence in lessening the virulence of organisms which they filter out. The prejudice that exists against the removal of diseased tonsils is ill founded, as whatever may be their use, they certainly cannot functionate when markedly pathological, and may and often do become a serious menace to the health of the individual.

During the past few years considerable attention has been given to the tonsils as portals of infection, and many somatic diseases have been traced to them as a starting point. Infection through the tonsils from various organisms may occur at any age, but is found more frequently in children than in adults. The susceptibility in early life is due to the greater development of the lymphatic system in childhood. Sappey, in his studies of the lymphatic system, was accustomed to use newly born infants for purposes of injection, and often found that the lymphatic vessels in various portions of the body could be injected in the newly born when it would be impossible to demonstrate them in older subjects.

Dr. Francis R. Packard, in the Wesley Carpenter lecture, reviews the subject carefully, especially in connection with acute articular rheumatism. He cites the studies which have been made on the flora of the buccal and pharyngeal cavities, enumerates the many pathological organisms frequently found, and mentions the protective function of the mucous membrane and secretions. Experiments upon ani-

mals have demonstrated that not only pigments but microorganisms may be taken up by the tonsils, and carried to the neighboring lymph nodes. Clinical experience gives abundant evidence that this frequently takes place, and that remote organs may become infected by the tonsillar route. In May, 1899, at the meeting of the Association of American Physicians, Packard reported five cases of endocarditis following acute angina. In three of these cases it was definitely known that the heart was normal before the attack of angina. During the attack endocardial murmurs developed; after the attack cardiac signs and symptoms persisted. This same author cites numerous instances reported by other observers where cardiac lesions followed acute amygdalitis. Mention is also made of the frequency of cardiac lesions without the history of preceding rheumatism, but with a history of one or more attacks of severe sore throat. A number of cases have been reported of pleurisy following acute amygdalitis, also a number showing the close relation existing between chorea and throat affections.

Koplik calls attention to the tonsils as portals of tuberculous infection. He mentions the possibility of a primary isolated process unaccompanied by tuberculous foci elsewhere. He cites the exceedingly rare case of Friedman's of a child, aged sixteen months, dying from causes other than tuberculosis, in which the tonsil was the only organ affected by the disease. The secondary forms of tuberculosis of the tonsils are more common. In both forms the cervical lymph nodes are involved. Children are more often affected than adults. Tuberculous ulcers of the tonsils are only rarely observed. One observer reports 19 cases of tuberculosis of the tonsils out of 161 specimens examined. There was no clinical evidence of tuberculosis of other organs. A case is reported supposed to be a primary tuberculosis of both tonsils with a distinct tuberculous ulceration of one tonsil. The patient was a male child, fifteen months old, who associated closely with his grandfather, a subject of tuberculosis. The tonsils and infected cervical glands were removed. Secondary infection of the larynx and lungs took place, which resulted fatally. Another case of a twelve year old girl is reported where the lymph nodes were tuberculous from tonsillar infection. Most writers believe that the inspired air plays but a small part, and that the infection is brought about through the ingestion of infected food. Hypertrophy of the tonsils predisposes to tuberculous infection. A case is reported of a child who died of tuberculous meningitis. The lymph nodes of the left side of the neck and the left tonsil were found tuberculous. Most of the organs were affected with acute miliary tuberculosis. Woodhead has demon-

strated in pigs that the course of tuberculosis is through the pharyngeal and tonsillar structures, through the glands of the neck into the thorax, and finally to the lung itself. A few cases of primary tuberculous infection of the tonsils have been reported, but a histological examination of a large number of tonsils, together with the examination of other organs, shows that the condition is rare. Wood from experiments has shown that the tubercle bacillus can pass through the tonsillar tissues into the lymphatics without causing any local disease in the tonsil itself.

Morse reports four cases of acute nephritis following amygdalitis. Two of these cases were in adults and two in children. In all it seemed possible to absolutely exclude scarlet fever and previous disease of the kidneys. Lymphatic leucemia, or Hodgkin's disease, may manifest itself primarily by tonsillar enlargement. Swain refers to a case of a young man, of twenty years, suddenly stricken with acute Hodgkin's disease following a simple streptococcic amygdalitis. Death resulted in six days. He cites another case where tonsillar enlargement was an early symptom, and eventually led to death. Cases are reported where skin eruptions have followed acute follicular amygdalitis. The marked toxæmia, with high temperature, which accompanies acute follicular amygdalitis, illustrates the absorptive power of the tonsils. Acute inflammation of the pharyngeal tonsil may occur in children with high temperature and all the toxic symptoms of a faucial amygdalitis.

Many other cases might be cited to illustrate the importance of the tonsils as portals of infection. There are a number of cases where mild, chronic infection is constantly taking place through the diseased crypts of the tonsils that are frequently not recognized. The enlarged cervical glands of childhood, and less often in adults, are examples of such infections. The large majority of children dying in foundling institutions from any cause have enlarged bronchial nodes. In cases of enlarged glands we ought to search for the site of infection. It may be found in the tonsils, nose, nasopharynx, mouth, or teeth. A tonsil does not have to be markedly hypertrophied in order to act as a portal of infection. It is necessary to examine a tonsil with a suitably bent probe for pockets or diseased crypts. An accumulation of cheesy material will be found frequently in one or more of these blind sacs. If this is removed, and the crypt destroyed, the source of irritation and infection will be removed.

The slow absorption of septic material is illustrated by the case of a medical student examined several years ago. He had had a small glandular swelling near the angle of the jaw, on the right side,

for several months. It varied somewhat in size, but never disappeared. An examination of the pharynx showed the right tonsil to be slightly enlarged, but with a probe a deep pocket filled with cheesy material was found. The crypt was destroyed by the galvanocautery, and without further treatment the enlarged gland completely disappeared. Cases occur where the general health is impaired by the slow absorption of septic material from the throat. Many delicate children, who are poorly nourished, peevish and fretful in disposition, and susceptible to changes in temperature and humidity, are sufferers from chronic toxæmia. This condition is usually accompanied by obstruction of free nasal breathing due to adenoids, which partly accounts for their condition. When nasal breathing is established, and sources of infection are overcome, these patients improve rapidly in general health. The writer has observed a number of cases of enlarged glands of the neck in childhood due to infection through the tonsils. A case of spasmodic torticollis has been seen recently which seemed to have as an ætiological factor an accumulation of cheesy material in a tonsillar crypt. A foul odor to the breath often accompanies this condition, and the swallowing of the infected material may cause gastric disturbance. On the other hand gastric disease and a coated tongue predispose to chronic lacunar disease of the tonsils.

TREATMENT.

The treatment of these various conditions depends upon the condition found after careful examination. There is some difference of opinion as to whether all hypertrophied tonsils should be removed. It seems that it is not necessary to insist upon the removal of every tonsil simply because it is larger than normal. If the tonsils are the source of obstruction or irritation, or if the crypts are diseased and the seat of septic absorption, then it is our duty to advise the removal of the tonsils or the destruction of the crypts. If, on the contrary, no symptom can be traced to the tonsil, then it is not necessary to urge their removal unless for the purpose of improving the voice or lessening the predisposition to frequent colds.

The treatment of enlarged tonsils may be divided into medical and surgical. Medical treatment may be of value to improve the general health, but neither constitutional remedies nor local applications have any permanent beneficial effect on a chronically hypertrophied tonsil. In fact, the long continued application of astringents, such as nitrate of silver, to the tonsils favors fibrosis, which is undesirable. The surgical removal of the offending tonsil is the easiest, the quickest, and the surest method of treatment. Electricity has limited value. The use of

electrolysis is slow, uncertain, and not to be recommended. The galvanopuncture destroys a certain amount of tissue with each puncture, which is followed by contraction, but if the tonsils are at all large, repeated punctures will be necessary and the reaction and pain following each application are nearly if not quite equal to those of their complete surgical removal. The fibrous scar tissue left after repeated punctures may in itself be the source of considerable irritation. The galvanocautery is of value when a single crypt is to be destroyed. The bent electrode is passed to the bottom of the pocket, and the current turned on, and the heated electrode is drawn toward the median line, cutting through the intervening tissue. This converts a blind pocket into a furrow which, as it heals from the bottom, obliterates the crypt. The crypt can also be opened by a bent tonsil knife, and trichloroacetic acid applied.

In the majority of cases it is more satisfactory to remove the tonsil. The method most often used is by one of the many forms of amygdalotomes. In children, where the tonsil is soft and projects from between the faucial pillars this is a quick and usually satisfactory method. The hæmorrhage generally ceases within a few minutes. In adults, and in all cases where the tonsil is adherent to the pillars, or is flat and irregular, the results with the amygdalotome are not so satisfactory. It is difficult to engage the flat, irregular tonsils in the loop of the instrument, and in case of adhesions the pillars may be injured. In fibrous tonsils, the hæmorrhage may be severe and even dangerous.

One of several methods may be used for fibrous, irregular, or adherent tonsil; first, the galvanocautery knife; second, the dissection of the tonsils with a bistoury, curved scissors, or cutting forceps; and third, the snare. In all cases where adhesions are present the tonsil should be freed before any attempt is made to remove it. This may be done by any of the many forms of curved tonsil knives. The advantage of the galvanocautery knife for dissecting out the tonsils is that the danger of hæmorrhage at the time of operation is overcome. The disadvantages are more pain at the time of and following the operation; the formation of a slough, which increases the danger of sepsis and secondary hæmorrhage; and the danger of cauterizing the pillars at the time of the operation. Dissecting out the tonsils by means of the bistoury, scissors, or cutting forceps is a surgical procedure which gives good results, but the danger from excessive hæmorrhage is so real that this method finds little favor with the majority of operators. The cold snare has many advantages. It can be adapted to tonsils of different shapes and sizes. The tonsils can be cut through slowly, which minimizes the risk of hæmorrhage,

and there is little danger of injuring other structures. The tonsils can easily be grasped with a forceps, and pulled toward the median line, so that the snare can be made to grasp as much or as little as is desired. Care should be used not to pull the structures more than is necessary, as tension of the muscles is often followed by pain referred along the course of the stylopharyngeus muscle. The after-treatment consists of the use of antiseptic gargles or sprays until healing is complete. No operation is a success unless there is sufficient tissue removed to prevent the formation of pockets. Cases frequently come under observation with a history of having the tonsils "burned" or "cut" without any benefit and sometimes with positive injury. The explanation in the majority of cases is simple. Many apply the cautery to the surface of the tonsils, which closes the opening of the crypt and allows the secretions at the bottom of the crypt to form a retention cyst or, if infected, an abscess. This retention of the secretions often causes considerable irritation, with cough and a constant desire to clear the throat. The improper or partial removal of the tonsil may lead to a similar result. There is an ill founded fear that the removal of the tonsil may injure the voice. The removal of diseased tonsils improves the voice in proportion as it restores the pharynx to a more nearly normal condition. The voice becomes clear and more resonant. Injury may be done to the flexibility of the voice if the faucial pillars are injured.

The keynote to the successful treatment of catarrhal affections of the nose and throat is to remove the causes which impair respiration and excite irritation, and when this is done, the danger of infection through the nasopharyngeal mucous membrane is reduced to the minimum.

912 CHAMBER OF COMMERCE.

The Société Internationale de la Tuberculose, the object of which is to study the most efficacious means of defense against treatments of tuberculosis, held its general annual meeting in Paris on March 14th, under the presidency of Mr. Richelot, member of the French Academy of Medicine. After an address by Dr. Samuel Bernheim, in which he clearly set forth the actual state of the question, the society proceeded to elect its bureau for 1905 and 1906, and the following gentlemen were elected:

President, Professor Lancereau, of the French Academy of Medicine, of Paris; vice-presidents, MM. Huchard, Richelot, S. Bernheim, of Paris; Professor von Schrötter, of Vienna; Sir Hermann Weber, of London; Professor de Lancaster, of Lisbon; general secretaries, George Petit, of Paris; Count Ivan Tolniewski, of London; treasurer, M. Papillon, of Paris; assistant treasurer, M. L. Garnier, of Paris; secretaries of séance, MM. Tartiére, Bourdin, Richelot, and Chauveau, of Paris; archivist, M. Ruault, of Paris.

All applications for membership, etc., to be addressed to Dr. George Petit, 51 rue du Rocher, Paris.

MODERN MOTHERHOOD.

By THERESA BANNAN, M. D.,

SYRACUSE, N. Y.

There are religious communities whose members spend their lives in prayer to atone for the impiety and wickedness of the world. So there are women who by their yearning for maternity unconsciously expiate the sins of their sisters who desecrate the holy temple of motherhood.

The ideal mother is fast passing from the scene, and though she may reappear from time to time, the atmosphere of these days will long cling to her garments. The time has passed when the young bride easily and naturally assumed the duties of her wifehood, when children were accepted as gifts of God and sterility bemoaned as a sign of His displeasure. To-day, even the maiden will flippantly disclaim ambition of her natural office, so widespread is the doctrine which threatens the existence of nations. The superb American woman in society, in the professions, in the home, the shop, the factory, the kitchen, is the apostle of this doctrine which dwarfs her whole being. Her most faithful follower is her husband, who gives her instruction and aid in their common immorality.

The diminishing birth rate among the most progressive nations is well recognized, but its cause and its remedy are both equally obscure. Many theories explain it in part, but there yet remains the fact that the vast majority of those upon whom unwilling the duty of reproduction rests have no other reason than their own will and pleasure. They give many reasons, which in their very multiplicity confess their weakness. They do not want children and will not have them is the final argument, and whatever causes this state of mind will explain the diminishing birth rate.

It required many centuries to teach man to limit the number of his offspring by art, but after half a century of such knowledge it becomes necessary to teach him the duty of procreation. God alone has the power to give life, yet man dares to hinder and destroy. The bride, most unwisely learned, leaves the fruitful path for the barren highway. Her instincts are conquered by her own selfishness, her husband's acquiescence, and the commiseration or scoffs of her friends who successfully evade their duties. Evil counsel leads her to the druggist, the physician, or the professional homicide until the fair robes of maternity are torn and bedraggled. Augury inauspicious when she who is well seeks the healer of the sick to invite disease. Yet the young

woman, with the mother love just beginning to shine in her face, with her whole being answering the impulse of her unborn, will hold to her stubborn resolve and turn deaf ears to argument or entreaty, dominated by an influence opposed to her well being, an influence which degrades, defiles, and slays. Fountains of tears and infinite yearning never bring back that hour of choice. The mind conscious of wrong is a persistent avenger.

There are many types among the voluntary barren and the sporadically fruitful. Without the infusion of new blood the natural tendency of families and nations is to extinction. Sterility is a stigma for which heaven has been wearied by prayer, and rites, and sacrifice.

Caspar: Calphurnia,

Stand you directly in Antonius's way
When he doth run his course. Antonius,
Forget not, in your speed,
To touch Calphurnia: for our elders say
The barren, touched in this holy chase,
Shake off their sterile curse.

In these days extinction is anticipated, sterility is invited and bears no reproach. The few who bemoan it as a curse are lost in the crowd who seek it. Here are the barren from choice, who prevent conception. Here are those who repeatedly destroy the product of conception by drugs, or instruments, or other means. Many by such practices bring upon themselves diseases which cause sterility. Many by preventing conception find themselves at last unable to conceive, and their cleverness only too effective. Those who risk and contract venereal disease swell the ranks of the voluntarily unfruitful.

The sporadically fruitful woman may bring forth one child, or several children at long intervals, as her pleasure dictates. Or, having borne one or more, she refuses another burden, either dreading the pains of childbirth or having been lately instructed in the doctrine of prevention. Many, advised by their physicians of ailments which might make child birth dangerous, accept his opinion with a docility unwarranted by his learning or skill, and follow his advice with a fidelity most unusual and exemplary.

These subjects are treated and discussed with a levity which has no relation to morality or conscience. A few decades ago public opinion stamped a woman suspected of these practices so that children fled in terror at her approach. Now the giant who consumed boys and girls is a forbidden story, while "mothers but smile when they behold their children quartered."

The significance and enormity of the diminishing birth rate in this country is masked by the

tide of immigrants who, for a time, increase and multiply. But soon these very people note, admire, and imitate the habits of their neighbors.

Before this union of elements, the most populous nation may well fear for its future existence. "The wages of sin is death," but "there is not in the mind of man a passion so weak but it mates and masters the fear of death."

There is not one sound argument in favor of these practices. Nature herself cries out against them, and idle, indeed, and vain the crusade to bring their followers back to her ways. Relentlessly she avenges herself by the survival of the fittest.

503 WARREN STREET.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 808.)

Adrin (epinephrin hydrate), the active principle of the suprarenal gland, as made and marketed by the H. K. Mulford Company, Philadelphia, is now supplied in the following new forms and combinations: Adrin powder, almost white, stable, non-hygroscopic. Adrin 1 to 1000 solution. Adrin tablets 0.001 gramme ($\frac{1}{85}$ grain) for the extemporaneous preparation of 1 to 1000 solution; each tablet dissolved in 1 c.c. (15 minims.) sterile water yields a 1 to 1000 normal saline solution. Adrin suppositories contain $\frac{1}{25}$ grain of adrin, the equivalent of 40 minims of a 1 to 1000 solution. Adrin throat tablets are composed of adrin, $\frac{1}{800}$ grain; menthol, $\frac{1}{35}$ grain; acid benzoic, $\frac{1}{12}$ grain; oil gaultheria, $\frac{1}{10}$ grain; eucalyptol, $\frac{1}{16}$ grain; and sugar, q. s.

Cornutol is the proprietary name for a concentrated and permanent preparation of ergot of rye intended for hypodermic and general use. The following claims for cornutol are made: (1) It contains all of the effective principles of ergot and is absolutely pure and therapeutically active; (2) it is free from fat and all substances which irritate and cause abscesses, and is aseptic; (3) it does not produce nausea when administered by the mouth, and may be given in repeated doses without cumulative effect; (4) it is a stable product, not being affected by age or temperature; (5) it is the most eligible of all preparations of ergot for hypodermic use, since it is freely soluble in water and the solution remains perfectly clear; (6) it is highly concentrated, 1 minim representing $2\frac{1}{2}$ grains of the best Spanish ergot; (7) its therapeutical effect can always be relied upon, since it is carefully assayed and standardized, both chemically and physiologically. The dose is, hypodermically, 5 to 30 minims (or $\frac{1}{8}$ to 2 c.c.); by the mouth, 10 to 30 minims, or $\frac{2}{8}$ to 2 c.c. Cornutol is furnished in 1 ounce vials, and in hermetically sealed aseptic bulbs, each bulb containing 2 c.c. (30 minims).

Epinephrin Hydrate is the chemical designation of adrin, the active principle of the suprarenal gland.

Hæmatosin is stated to consist of a composition of the following ingredients: Albumin, 35 parts; organic iron, 7 parts; nutritive salts (Nährsalzen), 3 parts; blood salts (Blutsalzen), 2 parts; pepsin, 3 parts; sodium glycerophosphate, 5 parts; lecithin, 1 part; malt, 15 parts; oatmeal, 15 parts; and cocoa, 15 parts. It is administered in doses of one teaspoonful, either cooked in water or milk or mixed with lemonade, beer, or wine.

Ichden is the name applied in Switzerland to an ichthyol substitute which in other countries is known as piscarol. It is understood to have the same chemical composition as ichthyolammonium sulphionate.

Ichthyokreosote is a compound of ichthyol, 1 gramme; creosote, 1 gramme; eucalyptol, 0.05 gramme, with an excipient, which originated in France; it is recommended in the treatment of pulmonary disorders.

Iodinol is an iodized sesame oil, similar to iodipin.

Iodoil is a dry, powdered preparation, similar in constitution to bromoil, but owing its activity to iodine.

Iothion is a combination of iodine and mustard oil, containing either 10 per cent. of iodine and 1.6 per cent. of sulphur, or 25 per cent. of iodine and 2.5 per cent. of sulphur. The union between the two is a chemical one. Iothion is in the form of a syrupy, yellowish brown liquid, and may be used internally or by subcutaneous injection.

Iodgelatin is made by melting a mixture containing gelatin, 3 grammes; potassium iodide, 2 grammes; iodine, 1 gramme; water, 100 grammes; sodium and calcium hypophosphites, of each 2 grammes. When filtered, this makes a clear, colorless solution, and is believed to be well adapted for internal administration where iodine is indicated.

Isoform is an iodoform substitute, the correct chemical name of which is paraiodanisol. It is obtained by the oxidation of iodanisol. It forms glittering silvery scales, sparingly soluble in cold water, more soluble in dilute acetic acid, insoluble in alcohol and in ether. The pure body is not put on the market, but the powder, consisting of equal parts of calcium phosphate and isoform, is supplied. Isoform paste, containing equal quantities of isoform and glycerin, is also prepared. Isoform is given internally as an intestinal disinfectant, as well as being employed as an external bactericidal preparation. In the latter connection, a 1.3 and 10 per cent. isoform gauze is employed as a protective for wounds.

Itrol Crede is a silver citrate in a state of extremely fine powder, which is intended for use in the treatment of diseases of the eye. It is put up in small black bottles containing 0.5 gramme and 1 gramme. Itrol is very sensitive to light and air, and cannot be kept longer than two weeks if the container is frequently opened.

NEW YORK, SATURDAY, APRIL 29, 1905.

THE BACTERIOLOGY OF PNEUMONIA IN INFANCY.

Dr. Martha Wollstein, of the Babies' Hospital, New York, has recently made a notable study of the pneumonia of infancy from the bacteriological point of view, and she gives an interesting account of her observations in the February number of the *Journal of Experimental Medicine*. They were made on the cadavers of a hundred infants that had died of the disease. The areas of consolidation were rapidly exposed, and the author lays some stress on the fact of their not having been subjected to heat in the process of taking the specimens, and on the fact that glucose, glycerin, and agar formed the culture medium in the experiments.

In age the infants, fifty-six boys and forty-four girls, ranged from eighteen days to three years and a half, but the great majority of them were less than a year and a half old. In thirty-three cases of primary bronchopneumonia, the pneumococcus alone was found in fifteen, associated with the streptococcus in seven, and with *Staphylococcus pyogenes aureus* in two; the streptococcus alone in two, and associated with *Staphylococcus pyogenes aureus* in two; the staphylococcus alone in two, and associated with *Bacillus coli communis* in one; and the streptococcus and *Oidium albicans* in one. In all but four of the cases the pneumonic areas

were scattered, and in sixteen the whole or the greater part of one or more of the lobes was affected. In eleven the pleura was normal; in the others it was covered with fibrin or pus. In twenty there was pus in the bronchi, in the pleural sac, in pulmonary abscesses, or infiltrated.

The remainder of the study was devoted to secondary pneumonia associated with athrepsia, enterocolitis, diphtheria, measles, meningitis, cerebral abscess, malarial disease, septicæmia, or tuberculous disease. The author gives useful references to similar research work by Dürck, Netter, Neumann, Mosny, Queisner, Blumer, and Pearce.

THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOUS DISEASE.

The importance of this subject calls for its frequent and careful consideration, and the public should be thankful to the Illinois State Board of Health for a very valuable pamphlet recently issued by it. The multifarious aspects of the matter are handled in the board's accustomed admirable manner, "Every suspected case," says the pamphlet, "should be treated as a suspected case and examined accordingly. More cases of tuberculosis are overlooked for want of examination than for lack of knowledge on the part of the physician." The diagnosis should be made as soon as possible, and then there should be no concealment of the nature of the disease; hesitation to inform the patient himself as to its nature is indefensible at the present day, in view of the resources now at our command for virtually curing the disease.

Perhaps there has of late years been too great a tendency to underrate the importance of the family history. It is pointed out in the pamphlet that the peculiar type of chest and tissue that indicates less than the normal power of resistance to tuberculous infection is perhaps inherited; and, moreover, that the previous occurrence of tuberculous disease in a given family, if we assume that the family remains in the same habitation, furnishes a probable source of infection. In addition, the patient's personal history, especially as to such points as age, occupation, habits, manner of life, and previous illness, should be taken into account.

In his general remarks on these matters the writer of the pamphlet teaches much that both the profession and the community at large ought to bear constantly in mind with regard to incipient tuberculous disease of the lungs, and he follows them with what we must pronounce a most excellent condensed treatise on the early diagnosis of such disease. In this pamphlet the Illinois State Board of Health has added notably to the services it had already rendered to the public health.

CONDITIONS OF HEALTH IN THE BAHAMAS.

Dr. Clement A. Penrose tells, in an interesting pamphlet, published under the auspices of the Geographical Society of Baltimore, the story of the part that he took in a recent expedition to the Bahama Islands. Many topics are touched upon by Dr. Penrose, but we have not the space to mention more than a few of them.

It seems that race peculiarities may be studied to advantage in the scattered little islands. Some of them are inhabited entirely by whites, who have excluded the blacks; and in some others the blacks have almost wholly excluded the whites. The white inhabitants show a decided mingling of races, being descendants of early Spanish, English, and American colonists, and in some localities intermarriage has been carried to an extent that is thought to account for a considerable prevalence of bodily and mental abnormalities. Moreover, there has been much miscegenation, for between the pure whites and the pure blacks every gradation of color is to be found.

Dr. Penrose tells us that leprosy is becoming prevalent in the islands, but that no attempt at isolating the lepers has been made, save in Nassau, on the island of New Providence, where there is a retreat for them, to which, however, they resort only on their own volition. He properly remarks that the geographical and commercial relations of the islands make it important that the disease should be thoroughly studied and the lepers segregated. There is a great prevalence of diseases of the organs of special sense, especially the eye, and on most of the islands there seems to be no provision at all for medical attention, the inhabitants having nothing of the sort to depend on

beyond the chance visits of physicians, visits which they consequently hail with delight.

THE ÆTIOLOGY AND TRANSMISSIBILITY OF CARCINOMA.

It is clinically quite as probable that carcinoma is contagious as that tuberculosis and leprosy are transmissible. This theory may, for that matter, be quite in accord with the views of the two great schools which have been at war upon this question, one considering cancer as a constitutional or diathetic affection, a disease of the blood, the other believing it to be a purely local affection from its beginning. This latter hypothesis being admitted, carcinoma may be likened to a soft chancre, and consequently should be both contagious and inoculable. It is well known that carcinoma has not been inoculated, at least up to the present time; the great number of essays which have been undertaken during the last twenty years, not only on animals, but also on man, have all failed, or at least have given only such uncertain results that it has been quite impossible to draw any conclusion. In man, inoculations have been made at different times, but have given no marked results. The contagiousness can consequently be demonstrated only by clinical data, and not only are facts of this kind of extreme rarity, but they also lack the necessary precision for conclusions which cannot be attacked.

Cases of carcinoma have been observed in several members of the same family or among people living under the same roof, but all such instances can always be explained as simple coincidences. Thus, for example, cases of epithelioma of the penis have been observed in husbands of women afflicted with carcinoma uteri, and it is precisely upon this fact that we base ourselves in order to combat the theory of contagion. All general practitioners meet with many cases of carcinoma of the uterus, but they very infrequently encounter carcinoma of the penis. Is there a more sensitive mucosa or one more susceptible to inoculation than that of the glans? And is there an organ more favorable to morbid receptivity? Now, it is well known that epithelioma of the penis is a very rare condition, while malignant tumors of

the uterus are of extreme frequency. Uterine carcinoma may be present for a year or even more, manifesting itself by slight clinical symptoms without any reaction on the general health and not even attracting the patients' attention. During this period the women have a sexual existence of a most active nature, and coitus has been practised hundreds and thousands of times without any distinctive fact of contamination resulting. I have had under my care a number of prostitutes afflicted with carcinoma of the cervix, all having frequent sexual relations with different individuals; if transmissibility were possible, it would certainly have occurred, because the intimate contact of the glans, often excoriated, with the cervix during coitus about equals an attempt at inoculation. It would seem probable, for this reason, that one cannot invoke carcinoma of the penis as a proof of contagion; the extreme infrequency of malignant growths of the penis, compared with the frequency of these same tumors in the cervix, would appear, on the contrary, the very best demonstration of the non-transmissibility of the disease.

As to other cases of carcinoma observed in members of the same family, they appear to me to demonstrate, not contagion, but heredity, a fact that all writers since Hippocrates have been unanimous in recording. The results of recent statistics made in Holland, Germany, and Italy have shown that heredity occurs in twenty per cent. of cases of cancer. Consequently heredity is found in one case out of every five, and it would seem that this was an ætiological point which should particularly meet with attention, rather than those very doubtful observations of direct contagion.

At the present time it would appear that the ætiology by contagion is quite *à la mode*, especially since a large number of physicians have proposed specific sera. Far be it from me to contest the value of certain therapeutic procedures which time alone can settle and which always give hope to patients, at the same time that they often relieve the practitioner who is at the end of his resources in hopeless cases. I would say only, apropos of the new sera which have recently been noisily announced, that other sera quite as effi-

acious have already been put on the market in preceding years and have died. I do not condemn the proposed therapeutic methods in hopeless cases; I desire only that they be inoffensive and honestly applied. I consequently believe that it is not in the theory of contagion that one will find either scientific or therapeutic indications.

Apart from measures of cleanliness, of prophylaxis, and of hygiene, which impose themselves upon healthy as well as cancerous individuals, apart from the moral satisfaction that every human being feels in the idea that the disease which attacks him is *not born in him*, but has been communicated to him by another, apart from these general considerations, where does the hypothesis of contagion lead us from the therapeutic standpoint? To nothing. Now, medicine is not only prophylactic, but is above all curative, and I consequently believe that the rational therapeutics of cancer must be looked for elsewhere than in the hypothesis of contagion. In the first place, I believe that the microbic theory should be given up; it has been a thick cloud which for twenty years past has kept physicians from entering into true pathological research, and it is now time to return to the starting point of all formations of normal or abnormal tissues; in other words, the cell. Before endeavoring to ascertain whether or not carcinoma can be transmitted from one individual to another, one should first learn how the neoplasm forms in the individual and how it becomes transmitted from one tissue to another in this same individual. It is in the cell transformation, in the intranuclear changes which the normal cell undergoes, that the ætiology of carcinoma should be looked for, and it is just on this side of the question that the most recent researches have been carried.

Carcinoma has been the object of most important work in England, started under the inspiration of a committee with the patronage of the King, who has given a considerable amount of money for carrying out this work. In the first paper, which was published in the *Lancet* on December 26, 1903, relative to the analogy existing between the development of the cells of malignant tumors in man and the normal cells of the tissues of reproduction, Professor Farmer makes

the following observation: 1. Mitotic phenomena are identical in all somatic cells. 2. These mitotic phenomena are different in the cells which develop in the ovaries and testicles, forming what this authority designates under the name of heterotypic mitosis. Now, observation has led experimenters to this interesting remark, that in malignant tumors the nuclear division is far from being that of the type occurring in the somatic cell, and comes nearer to the mitosis observed in the cells composing the tissues of the reproductive organs. To sum up, cell mitosis is normal, or homotypic, in benign tumors, and heterotypic in the tissues composing carcinoma.

This analogy in the development of carcinomatous tissues and the development of the organs of reproduction had already been pointed out by Beatson, of Edinburgh, in 1896, who emitted the opinion that carcinomata consisted in an epithelial proliferation similar to that observed in germinative epithelium. He also adds that, in his way of thinking, the carcinomatous process might be explained by the fact that the epithelium of the affected mucosa had taken on the properties of germinative epithelium. As may be seen, this hypothesis is relatively confirmed by recent researches. It may be added that Beatson endeavored to apply his theory in practice by performing double oophorectomy in women having "inoperable" carcinoma of the uterus. This therapeutic measure, imitated by a certain number of operators, has appeared to give favorable results, inasmuch as it has retarded the evolution of the uterine neoplasm.

The still more recent writings of Bashford and Murray have confirmed Farmer's opinions. I will merely mention the essential points: 1. Vertebrate animals have the same malignant tumors that occur in man, and these growths present identical characters in their histology, pathology, and clinical course. 2. A carcinoma of one animal cannot be transmitted by inoculation to another, but only by transplantation, or graft; the cell reproduction takes place only in the portion of the tumor transplanted and not in the tissues of the animal upon which it has been transplanted. These authorities come to this general conclusion, that carcinoma is a local and abnormal manifesta-

tion of a process which occurs naturally in all organized beings. But before making any deductions from these facts, it is well to take into consideration the judicious observation of Isch-Wall, on the coexistence of leucocytosis and malignant growths. Lutaud has made the same observation, but he has not been able to determine whether the leucæmia is the consequence or the cause of the carcinoma, though he believes that both theories may be upheld.

It is evident that the general condition designated under the term cachexia, which is always met with when a malignant growth has exercised its ravages on the economy, is nothing other than a leucæmia of unknown cause, but does leucæmia predispose to carcinoma when it exists before the appearance of the growth? The observations made by Lutaud lead him to suppose that it does. Now, it is well known that leucæmia always coincides with an exaggerated development of the lymphatic vessels and with an abnormal production of lymphoid tissue; this shows that there already exists a tendency to cell proliferation which, in the first place normal, constitutes a morbid process by excessive proliferation, but it is very probable that the development of the lymphatics can only favor the rapid development in the organism of the cancer cells which form accidentally at some point of the economy.

The migration of the morbid cell is one of the most interesting features of the pathology of carcinoma, and one may rightly ask why malignant tumors have a tendency to rapidly invade other tissues than those in which they start, while benign tumors, the type of which is represented by lipomata, usually remain localized. It is because a carcinomatous growth is almost always wedged in healthy tissues without any limiting capsule, and mitosis takes place without any hindrance, rapidly extending into the neighboring structures by a proliferation of newly formed germinative cells. It is consequently quite rational to admit that lymphadenia considerably aggravates the prognosis of carcinoma by favoring the migration of the morbid cell.

To sum up, it may be said that carcinoma is neither a constitutional nor a diathetic disease; it cannot be inoculated, and no experiments ob-

served up to the present time can allow one to conclude that it is contagious. Carcinoma has always a local origin due to the abnormal proliferation of cells normally existing in the body. The initial production of the cell which determines the malignant growth does not differ greatly from the abnormal production which results in the formation of the so called non-malignant neoplasms. The gravity of the prognosis appears to be due to the absence of encapsulation of the growth, to the development of the neighboring lymphatics around the point at which the morbid cells have taken their origin. Leucæmia appears to favor the rapid development of carcinomatous tissue and its generalization throughout the economy.

CHARLES GREENE CUMSTON.

A GRAVE ACCUSATION.

At a recent hearing before a legislative committee of the State of New York, on the optometry bill, a supporter of the bill read a letter from an optician in which it was stated that for fourteen years the writer had paid to about sixty physicians commissions varying from twenty-five to fifty per cent. of his charges for executing their orders, but that two years ago he had refused to continue the practice, whereupon the physicians concerned had used their influence in favor of those of his competitors who were still willing to pay them a commission. Hence, he remarked, the physicians who opposed the bill were not altogether disinterested. A representative of the legislative committee of the Medical Society of the State of New York was present at the hearing, but of course he could not on the spot refute the statements made in the letter. It is to be hoped that they can be refuted, although they are by no means important as affecting the fate of the bill.

EXPERIMENTAL ARTERIOSCLEROSIS.

At a recent meeting of the Society of Vienna Physicians (*Wiener klinische Wochenschrift*, 1905, No. 6; *Berliner klinische Wochenschrift*, March 27th) Dr. Ludwig Braun reported that he had varied Josué's experiments in producing arteriosclerosis in rabbits by intravenous injections of adrenalin in that he had injected amyl nitrite at the same time, and yet the arterial sclerosis had followed. This showed, he remarked, that its production was not due to the action of adrenalin in raising the blood pressure, but to its action as a poison. The subject seems worthy of further investigation.

THE DOCTOR'S CARRIAGE.

In our large cities the distinctive vehicles formerly used by physicians are fast disappearing, partly, perhaps, because the public conveyances have been so improved that they meet the needs of a practitioner having a large amount of visiting work to do, and partly because the few motor carriages that are owned by physicians do not differ in appearance from those employed by the general public sufficiently to attract notice.

AN UNUSUAL MERCURIAL RASH

The exceeding sensitiveness of some persons to mercury is well shown by a case reported by Dr. Max Joseph, of Berlin (*Dermatologisches Centralblatt*, October, 1904; *Berliner klinische Wochenschrift*, March 27th). The rash, which appeared on the face, followed the filling of teeth with amalgam, and disappeared on the removal of the fillings.

Obituary.

COLONEL CHARLES SMART,

OF THE MEDICAL CORPS OF THE ARMY.

Dr. Smart died in St. Augustine, Florida, on Sunday, April 23rd, aged sixty-four years. He was Scotch by birth. He served as a medical officer of a New York regiment of volunteers in the civil war, and entered the medical corps of the regular army in 1864. His service in the army was varied and always creditable. Three years ago he became an assistant surgeon-general with the rank of colonel.

It was not in the military service alone that Dr. Smart was known and esteemed. He long ago won an honorable rating with the profession at large by reason of his numerous investigations in the interest of sanitation, on which subject many valuable reports of his have been published. In addition, he was the author of a very popular book entitled *Handbook for the Hospital Corps of the United States Army and State Military Forces*, which appeared in 1889.

PATRICK J. LYNCH, M. D.,

OF NEW YORK.

Dr. Patrick J. Lynch, a well known physician of New York, died on April 21st. Dr. Lynch was born in Virginia, County Cavan, Ireland, in 1828, and came to the United States fifty-five years ago. Taking up the study of medicine, he graduated from the University of the City of New York in 1857, and was chief of clinic to Dr. Valentine Mott for several of the latter years of that great surgeon's life. He is survived by his wife and seven children, one of whom, Dr. Charles T. Lynch, is a practising physician in New York. The deceased gentleman was a member of several important medical societies. In addition to the beneficent practice of his profession, he was active in the charitable work of the Roman Catholic Church.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 1st.—New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association; Hartford, Conn., Medical Society; South Pittsburgh, Pa., Medical Society; Chicago Medical Society.

TUESDAY, May 2nd.—New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society (Jersey City; annual); Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, May 3rd.—New York Academy of Medicine (Section in Public Health); New York Genitourinary Society; Harlem Medical Association of the City of New York; Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association.

THURSDAY, May 4th.—New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis.

FRIDAY, May 5th.—Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Manhattan Clinical Society, New York.

SATURDAY, May 6th.—Manhattan Medical and Surgical Society, New York (private); Miller's River, Mass., Medical Society.

NEW YORK

Change of Address.—Dr. Frederick M. Ives, to 213 West Seventy-ninth Street, between Broadway and Amsterdam Avenue. Telephone number, 3364 Riverside.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending April 22, 1905:

	April 22.		April 15.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	356	16	473	9
Diphtheria and croup	294	42	325	31
Scarlet fever	212	12	269	11
Smallpox	2	..	1
Chickenpox	61	..	180	..
Tuberculosis	314	189	372	175
Typhoid fever	7	16	6
Cerebrospinal meningitis	111	104	182	117
	1,363	370	1,710	350

Marriage.—Dr. William Sturgis Thomas, chief surgeon of the out-patient department of St. Luke's Hospital, was married on April 25th to Miss Emma Rheinfrank.

The New York Medical Association has elected the following officers: President, Dr. Francis J. Quinlan; first vice-president, Dr. John A. Bodine; second vice-president, Dr. H. H. Seabrook; secretary, Dr. W. R. Stone; corresponding secretary, Dr. Charles G. Child; treasurer, Dr. Charles E. Denison. Dr. H. A. Dodin was elected a member of the executive committee for three years.

City's Gift to Hospitals.—At the annual meeting of the distribution committee of the Hospital Saturday and Sunday Association, held in Mayor McClellan's office in City Hall on April 18th, \$76,000 of city money was apportioned among thirty-eight hospitals and charitable institutions upon the basis of charitable work done by them last year. The Montefiore Home and Hospital heads the list with \$7,600, and the New York Ophthalmic and Aural Institute ends it with \$250.

American Gastroenterological Association.—At the eighth annual meeting of this association, held at the Academy of Medicine, New York, April 24 and 25, 1905, the following officers were elected for the ensuing year: President, Dr. H. W. Bettmann, of Cincinnati; first vice-president, Dr. S. W. Lambert, of New York; second vice-president, Dr. John P. Sawyer, of Cleveland; secretary and treasurer, Dr. Charles D. Aaron, of Detroit; councillors, Dr. William G. Morgan, of Washington; Dr. A. L. Benedict, of Buffalo; and Dr. J. Kaufmann, of New York.

To Quarantine Meningitis Cases.—The weekly meeting of the commission appointed to investigate the spread of cerebrospinal meningitis was held April 22nd at the department of health building. While the commission does not feel in a position to advise the board of health, Dr. Darlington believes that the communicability of the disease has been sufficiently well established to warrant isolation. He said that in the future all such cases must be reported at once to the department. It is probable that the health department will order that all cerebrospinal meningitis cases in private houses be quarantined in the future.

Hospital Boat for Health Department.—At a cost of \$70,000 the New York Health Department is now building a hospital boat. It is to take the place of the *Franklin Edson*, and is to be used in transporting contagious cases from various parts of the city to North Brother Island, and also in returning convalescents from that island to their homes. The hospital wards, eight in number, will be on the main deck, all separately inclosed in steel, with air tight doors and windows to allow separate fumigation at suitable times. There will be room for six patients in each ward. The ceilings of the wards are to be dust proof. On the main deck will also be a small morgue. There will be room on the deck for an ambulance and a fire engine. The windows of the ward rooms will be large enough to escape through in case of an emergency. The hull will be of steel, with five water tight compartments. There will also be on board a powerful fire pump. The boat will be lighted by electricity. On the top deck will be a saloon for convalescents. The boat will be ready by next October.

The Late Dr. James Alexander Ferguson.—The following resolutions upon the death of Dr. James Alexander Ferguson were passed at a meeting of the medical board of Fordham Hospital, held April 1, 1905:

Whereas, The medical board of Fordham Hospital has heard with profound sorrow of the death of their colleague

and visiting surgeon, Dr. James Alexander Ferguson, which occurred March 7, 1905;

Whereas, Dr. James Alexander Ferguson was an esteemed member, and for several years president, of the medical board; he was a kind friend to many, and especially cordial in his relations with the younger members of the profession. Therefore be it

Resolved, That the members of the board hereby express their great grief at the removal of their esteemed colleague by death, and extend their sincere sympathy to the widow, relatives, and friends of the deceased;

Resolved, That a copy of this tribute to the memory of Dr. James Alexander Ferguson shall be spread on the minutes of this board, and a copy thereof be sent to the family and the board of trustees of Bellevue and Allied Hospitals.

(Signed) JOHN J. QUIGLEY, M. D.,
 president;
 THOMAS F. MAGUIRE, M. D.,
 secretary.

PHILADELPHIA.

Change of Address.—Dr. Elizabeth L. Peck, to 4113 Walnut Street.

Marriage.—Dr. J. C. Knipe and Miss Ruth D. Krauss were married on April 24th.

Municipal Hospital.—The following is the census of the Municipal Hospital for March:

	Remaining March 1.	Received.	Discharged.	Died.	Remaining April 1.
Diphtheria	51	85	62	15	67
Scarlet fever	93	48	44	2	95
Smallpox	0	2	0	0	2
Other diseases	1	6	1	3	3

Smallpox in Philadelphia.—Two cases of smallpox occurred in the city during March, the first to be reported since December, 1904. Both cases were imported, one from Mt. Union, Pa., and the other from York, Pa. Neither patient had ever been vaccinated.

Death.—Dr. D. Newlin Stokes died in Moorestown, N. J., on April 19th, in the seventy-second year of his age. Dr. Stokes graduated from Jefferson Medical College in 1854. He was a member of the board of managers of the State Asylum for the Insane at Trenton and a member of the Burlington County Medical Society.

Scientific Society Meetings for the Week Ending May 6, 1905.—Monday, May 1st, Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, May 2nd, Academy of Natural Sciences. Wednesday, May 3rd, College of Physicians; Association of Clinical Assistants, Wills Hospital. Thursday, May 4th, Obstetrical Society; Medical Society of the Southern Dispensary. Friday, May 5th, American Philosophical Society.

New Yorkers in Philadelphia.—Dr. A. Jacobi, of New York, addressed the Section in Medical History of the College of Physicians on Monday, April 24th, on The Most Eminent American Physician of European Birth.

Dr. Carl Beck addressed the Philadelphia County Medical Society on Wednesday evening, April 26th, on The X Rays in the Diagnosis of Tuberculosis of Bones and Joints.

Dr. James Ewing, of Cornell University, addressed the annual conversational meeting of the Pathological Society on April 27th on Some As-

pects of the Problem of Immunity in Typhoid Fever. A reception was tendered Dr. Ewing after the meeting at the University Club.

Bureau of Health Statistics.—In the division of medical inspection of the Bureau of Health, for March, 1905, 3,942 inspections were made, exclusive of schools; 614 fumigations were ordered, and 49 cases were reported for special diagnosis. One thousand and ninety-seven children were excluded from school; 355 cultures were taken; 79 injections of antitoxine given, and 765 vaccinations done. In the division of milk inspection 143,118 quarts of milk were inspected, of which 1,755 quarts were condemned. Chemical examinations were made of 129 specimens and microscopical examinations of 740 specimens. In the bacteriological laboratory 1,513 diphtheria inoculations were examined; 536 specimens of typhoid blood; 733 specimens of milk; 189 specimens of sputum; and 1,135 doses of antitoxine supplied.

Cerebrospinal Fever in Philadelphia.—Between January 1 and March 31, 1905, forty cases of cerebrospinal fever were reported to the Bureau of Health. Of these, 13 or 32.6 per cent., were fatal. Eight of the forty cases occurred in four houses, two in each house. From two of the houses the cases were reported on the same day. From the third house there was an interval of three days, and from the fourth house an interval of six days between the dates of the reports. In the last two houses, therefore, it is possible that the disease may have been transmitted from one individual to another. With these exceptions the authorities have had no evidence of the direct transmission from person to person. The cases are scattered all over the city. The majority of the cases occurred in persons between the age of one and twenty-one years. Only two cases were in children less than one year old.

The Health of the City.—During the week ending April 15, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever	147	21
Scarlet fever	36	2
Chickenpox	59	0
Diphtheria	63	12
Cerebrospinal meningitis	7	3
Measles	56	1
Whooping cough	21	2
Tuberculosis of the lungs	41	79
Pneumonia	64	4
Erysipelas	13	3
Puerperal fever	1	4
Trachoma	1	0
Anthrax	1	0

The total death rate for the week was 517, in an estimated population of 1,438,318, corresponding to an annual death rate of 18.69 per 1,000 population. The total infant mortality was 105; 87 under one year, 18 between one and two years. There were 28 still births, 19 males and 9 females. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 5; diarrhoea and enteritis, under two years, 25. The weather was rather warm. The thermometer recorded 74° on the tenth and 78° on the eleventh. There were two thunderstorms on the tenth; 1.25 inches of rain fell during the week.

GENERAL.

Medical Society of New Jersey.—The next meeting of the Medical Society of New Jersey will be held in West End, at the Hollywood Hotel, on June 20, 21, and 22, 1905, the dates previously given having been altered.

Youngstown, O., Antituberculosis Association.—The following officers of this association have been elected: President, Mayor W. T. Gibson; vice-president, Dr. C. R. Clark; secretary, Dr. J. L. P. Clarke; treasurer, Dr. B. Hirshberg.

Appointment of Medical Examiner, Boston.—Dr. William G. Macdonald, of Boston, has just been appointed by Governor Douglas medical examiner of Suffolk county, to succeed Dr. W. F. Draper, whose term of office expires June 30, 1905.

The Tompkins County, N. Y., Medical Society has elected the following officers: President, Dr. C. P. Biggs; vice-president, Dr. Edward A. Meany; secretary, Dr. R. Mandeville Vose; member of the executive committee, Dr. H. Burr Besemer.

The Yalobusha County, Miss., Medical Society was organized on April 4th and elected the following officers: President, Dr. J. S. Sanders; vice-president, Dr. L. T. Fox; secretary-treasurer, Dr. J. J. Landreth. Dr. H. L. Noel was elected delegate to the State association.

Montgomery County, Mo., Medical Society Organized.—The physicians of Montgomery county have organized a county medical society. The following officers were elected: President, Dr. J. L. Jones; secretary, Dr. M. M. Wheeler, of High Hill; treasurer, Dr. G. E. Muns, of Montgomery City.

Buffalo Quarantine Hospital.—Dr. C. F. Durand, of 76 West Genesee Street, Buffalo, has been appointed superintendent of the quarantine hospital. Dr. Durand's name was taken from the civil service list. The position pays a salary of \$1,200 a year. Dr. Durand succeeds the late Dr. John O'Hara.

Personals.—Dr. V. C. Vaughan has been elected president of the Michigan State Board of Health.

Dr. E. K. Herrmann has been reelected city physician of Ann Arbor, Mich.

Dr. Fred Grady Hodgson has been appointed to the staff of the Wesley Memorial Hospital, Atlanta, Ga.

The American Academy of Ophthalmology and Otolaryngology.—The Buffalo meeting of the American Academy of Ophthalmology and Otolaryngology will be held on Thursday, Friday, and Saturday, the 14th, 15th, and 16th of September, instead of August 23rd to 25th, as previously announced. George F. Suker, M. D., secretary.

The Association of Assistant Physicians of State Hospitals, of Ohio, has elected the following officers for the ensuing year: President, Dr. Nelson H. Young, of Toledo; vice-president, Dr. Edson C. Brown, of Massillon; secretary, Dr. Frank J. Latshaw, of Toledo; treasurer, Dr. Mary E. Cadwallader, of Dayton.

The St. Clair County, Mo., Medical Society, at its meeting on April 6th, elected the following officers: President, Dr. W. E. Wiatt, of East St. Louis; vice-president, Dr. Hugo Wangelin, of Belleville; corresponding secretary, Dr. George Hillgard, of Belleville; recording secretary, Dr. W. C. Spannagel, of East St. Louis.

Meeting of Suffolk District Medical Society, Boston.—The annual meeting of this society will be held at the Boston Medical Library this evening. The subject to be considered is The Treatment of Typhoid Fever. Papers are expected from Dr. F. C. Shattuck, Dr. Maurice H. Richardson, Dr. Mark W. Richardson, and Dr. C. D. Easton.

The Broome County, N. Y., Medical Society elected the following officers on April 11th: President, Dr. L. D. Farnham; vice-president, Dr. J. H. Martin; secretary, Dr. C. W. Greene; treasurer, Dr. W. H. Knapp. Dr. Orton and Dr. Greene were named as delegates to the State medical association to be held in New York in October. Dr. Farnham and Dr. Quackenbush were elected alternates.

Schuyler County, N. Y., Medical Society.—The Schuyler County Medical Society has been formed as a branch of the State Medical Society. Its objects are to promote fellowship among its members, elevate the standard of medicine and surgery, and protect the public from medical quacks. The officers elected for the first year are: President, Dr. M. L. Bennett; secretary, Dr. J. K. King; treasurer, Dr. D. W. Scutt. Dr. J. F. Barnes and Dr. G. C. Fordham constitute the legislative committee.

Birmingham, Ala., Medical College.—The eleventh annual commencement of the Birmingham Medical College took place on April 3rd at 8 p. m. Dr. B. L. Wyman, dean of the college, conferred the degree of doctor of medicine upon the following fourteen young men:

E. A. Wilson, Robert Nelson, E. G. Little, D. C. Walker, Marvin Scott, G. W. Wood, D. A. Painter, C. B. Crawford, J. G. Vance, J. A. Harris, Jr., F. W. McDonald, O. Manasco, R. C. Black, and J. S. Gray.

Physicians Licensed to Practise in Minnesota.—The State board of medical examiners has granted licenses to Dr. C. S. McKee, Dr. A. L. Laliberté, of Minneapolis; Dr. A. M. Cattauach, Dr. C. D. Conkey, of Superior, Wis.; Dr. H. Cannon, Dr. E. H. Bohland, of St. Paul; Dr. J. S. White, of Fort Snelling; Dr. D. Kalinoff, of Stillwater; Dr. F. R. Curney, of Chicago; Dr. P. H. Sundt, of Pine River, Minn.; Dr. W. A. McEachern, of Sandstone, Minn.; Dr. J. H. Fowler, of Tower, Minn.; Dr. C. H. Wall, of Mellen, Wis.; Dr. F. A. Christensen, of Lake Mills, Iowa.

The Union County, Miss., Medical Association was organized in New Albany on April 11th. Dr. F. W. Cullens, of Wallerville, was elected president; vice-president, Dr. W. A. Whitten, of Keownville; secretary-treasurer, Dr. H. N. Mayes, of New Albany. Dr. G. F. Cullens was elected delegate to the State association, with Dr. R. L. Goodman alternate. The first Mondays in Feb-

ruary, April, June, August, October, and December were fixed as dates for the regular bimonthly meetings.

First Naval Hospital in Philippines.—The first naval hospital established in the Philippines was thrown open for the reception of patients on the 14th instant. It is situated on high ground jutting out into the sea at Canacao, and has a capacity of eighty beds. It is expected that it will be of great value to the medical department of the navy. The hospital site was formerly occupied by an old Spanish hospital, every vestige of which was removed before work was commenced on the present hospital.

Lee County, Tenn., Medical Association.—A number of physicians of Lee county have organized the Lee County Medical Association. The following officers have been elected: President, Dr. T. A. Boggan; vice-president, Dr. J. A. Orr; and secretary and treasurer, Dr. W. C. Spencer. A board of censors was elected, composed of Dr. W. B. Holland, Dr. C. T. Keyes, and Dr. C. G. Stone. The members of this board were also made a committee on public health and legislation. Dr. W. C. Spencer was elected delegate to the State Medical Association, with Dr. T. F. Elkin as alternate.

Montgomery County, Md., Medical Association.—At the meeting of this association, held at Rockville on April 18th, the following officers were elected: President, Dr. Horace B. Haddox, of Gaithersburg; vice-president, Dr. Edward Anderson, of Rockville; secretary-treasurer, Dr. John L. Lewis, of Bethesda; censors, Dr. Edward Anderson, Dr. William L. Lewis, and Dr. J. H. Stonestreet; committee of legislation and public health, Dr. C. H. Mannar, Dr. J. H. Stonestreet, and Dr. Farquhar; delegates to State society, Dr. James E. Deets and Dr. Edward Anderson; alternates, Dr. William L. Lewis and Dr. O. M. Linthicum.

Oneida County, N. Y., Medical Society.—At the annual meeting of the Oneida County Medical Society in Utica on April 11th, the following officers were elected: President, Dr. Herbert G. Jones, of Utica; vice-president, Dr. Conway A. Frost, of Rome; secretary, Dr. F. H. Brewer, of Utica; treasurer, Dr. E. D. Fuller, of Utica; librarian, Dr. Smith Baker, of Utica; censors, Dr. Walter C. Gibson and Dr. M. J. Davies, of Utica; Dr. Charles Bernstein, of Rome; Dr. T. Z. Jones, of Waterville; Dr. Charles E. Smith, of Whitesboro; delegates to State Medical Society, Dr. T. H. Farrell and Dr. F. M. Miller, of Utica; Dr. H. D. White, of Rome.

Tennessee State Medical Association.—The following officers of this association have been elected for the coming year: President, Dr. Cooper Holtzclaw, of Chattanooga; first vice-president, Dr. S. W. Woodyard, of Greenville; second vice-president, Dr. Alfred Moore, of Memphis; third vice-president, Dr. A. F. Richards, of Sparta; secretary, Dr. George H. Price, of Nashville; treasurer, Dr. W. C. Bilbro, of Murfreesboro. Following the election of officers the meeting place for

next year was decided upon, and Memphis will get the meeting in 1906, and the by-laws prescribe the date, which is the second Tuesday in April of each year.

The Central District Medical Association, of Indian Territory, elected the following officers on April 12th: President, Dr. F. L. Watson, of Alderson; vice-president, Dr. Thomas J. Long, of Atoka; secretary-treasurer, Dr. Leroy Long, of South McAlester. The association will hereafter meet semi-annually, the next session being at Atoka, October 10th.

Fairfield County, Conn., Medical Society.—This society has elected the following officers for the coming year: President, Dr. W. J. Tracy, of Norwalk; vice-president, Dr. William S. Randall, of Shelton; secretary, Dr. Edward W. Smith, of Bridgeport; county reporter, Dr. Donald McLean, of Stamford; censor, Dr. F. M. Schavoir, of Stamford; fellows to State society, Dr. R. L. Higgins, of Norwalk; Dr. F. L. Smith, Dr. F. J. Adams, Dr. F. W. Stevens, and Dr. H. E. Smyth, of Bridgeport.

Association of American Medical Colleges.—A uniform minimum curriculum was adopted by this association at the Great Northern Hotel, Chicago, on April 10th. The requirements for matriculation were raised so as to make the term of preparation the full four years of the high school course, representing a certain specified number of hours' credit in each subject. A committee was appointed to pass upon the value of medical studies taught by colleges of liberal arts. The following officers were elected: President, Dr. Samuel C. James, of Kansas City, Mo.; first vice-president, Dr. William H. Earles, of Milwaukee; second vice-president, Dr. Eli H. Long, of Buffalo; secretary-treasurer, Dr. Fred C. Zapfee, of Chicago; judicial council, Dr. William J. Means, chairman, of Columbus, O.; Dr. Parks Ritchie, of St. Paul; Dr. Thomas J. Hawkins, of Denver; Dr. Randolph Winslow, of Baltimore; Dr. H. B. Ward, of Lincoln, Neb.; Dr. J. M. Dodson, of Chicago; Dr. George M. Kober, of Washington, D. C. The association will meet in Pittsburgh the third Monday of March, 1906.

Licensed to Practise Medicine in Massachusetts.—The following physicians have been licensed to practise in Massachusetts, having passed the examination held on March 14th and 15th:

Edmund Sanford Thomson, John O'Donoghue, George Floyd White, George Gibson Parlow, Frederick Marshman Kennison, Howard Fellows Morse, Walter Daniels Bieberbach, Marshal Fabyan, Edward Lawrence Salmon, Joseph Aloysius Trainor, Werner Adolf Reinhold Lagus, Fred Austin Stowell, Patrick Joseph Carney, Freeman Augustus Tower, Charles Sleeper Gilman, Lorne Wilborne Harris, Herbert Edmund Peckham, John William Lane, Joel Packard Bradford, Nathan Andrews Goddard, John Alexander MacDonald, Frank William Tilley, Abie Warren Sylvester, Eleanor Way-Allen, Charles Joseph Hanson, John Emen Gillis, David Damon Pratt, Orion Vassar Wells, Helen Francis Cleaves, William Entwistle Garlick, Frederick Dugdale, Archibald John Douglas, Joseph Simpson, Kent Oakley Brown, Walter Clement Kenney, Kendall Lincoln Achorn, Thomas McCurdy, George Henry Sanborn, Henry Church Pillsbury, Julian Dyer Lucas, Henry Harrison,

Archibald McMillan, John Bryant Hartwell, John Wilson Trask, Charles Bradley Russell, Margaret Elizabeth Carley.

Osteopathy Not Recognized as a System of Practice in Utah.—The governor of Utah, under date of March 20, 1905, has addressed the following letter to the Secretary of State:

Dear Sir: I have the honor to file in your office, without approval, Senate Bill No. 92, entitled "An Act to regulate the practice of osteopathy in the State of Utah, etc." In passing upon this act, I have kept in mind the fact that the object of medical legislation is not to benefit the doctors of any school or class, but to protect the public against practice in lines of medical work which the practitioner does not fully understand. Senate Bill No. 92 gives to osteopaths the right to practice minor surgery, and to treat cases, including contagious and infectious diseases, without having first passed examination before the regularly constituted board of medical examiners, in fundamental principles of medicine and surgery, as prescribed by the law. It appears to me that this would open the door for incompetent practitioners to enter our State. The present law seems to me to be broad enough to insure fair treatment to competent physicians, of all schools; and under its provisions osteopaths are allowed the privilege of practising, upon passing examination in the principles underlying their practice, before a board, consisting of graduates of various medical schools, and representing broad medical training and sympathy. And I believe that no one should be regularly licensed to practise even minor surgery without first passing a thorough examination in the fundamental principles of anatomy and surgical practice. Since, therefore, the present law seems to me sufficient, I am led to withhold my approval from this act.

Very respectfully,

JOHN C. CUTLER.

Statement of Mortality in Chicago for the Week Ending April 22, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Apr. 22, 1905.	Apr. 15, 1905.	Apr. 23, 1904.
Total deaths, all causes.....	558	548	643
Annual death rate per 1,000.....	14.56	14.35	17.41
By sexes.....			
Males.....	307	305	371
Females.....	251	243	272
By ages.....			
Under 1 year.....	108	105	96
Between 1 and 5 years.....	67	67	40
Over 60 years.....	100	96	154
Important causes of death.....			
Acute intestinal diseases.....	17	24	24
Apoplexy.....	15	11	19
Bright's disease.....	40	55	54
Bronchitis.....	25	30	21
Consumption.....	78	59	75
Cancer.....	32	23	23
Convulsions.....	12	6	16
Diphtheria.....	8	5	7
Heart diseases.....	45	51	57
Influenza.....	1	3	5
Measles.....	13	15	1
Nervous diseases.....	18	16	24
Pneumonia.....	72	84	141
Scarlet fever.....	3	..	6
Smallpox.....	2
Suicide.....	8	9	11
Typhoid fever.....	6	4	7
Violence (other than suicide).....	20	36	28
Whooping cough.....	8	15	..
All other causes.....	135	113	123

Except for the almost epidemic prevalence of measles and whooping cough, heretofore noted, public health conditions are unusually satisfactory for the season of the year. The total deaths from all causes recorded during the week are 85 fewer than for the corresponding week of last year and the decrease represents a decrease of more than 16 per cent. in proportion to population. As to the two child diseases above mentioned the health department can do nothing but repeat its warning to those having charge of the young: Guard them against exposure. It is hoped that the Easter recess and the cleansing of the

school buildings may help to check further spread of the contagions.

Nebraska State Medical Association.—This association will hold its thirty-seventh annual meeting at Beatrice, May 2, 3, and 4, 1905. The following papers are expected:

Oration in Medicine, He's Only a Doctor, by Dr. P. E. Plumb, of Gothenburg; Oration in Surgery, Surgical Enthusiasm. Is it Declining? by Dr. S. C. Beede, of David City; Oration in Obstetrics and Gynecology, Ideals, by Dr. M. L. Hildreth, of Lyons; A Plea for Surgical Intervention in Suspected Malignant Disease of the Abdominal Cavity, by Dr. B. B. Davis, of Omaha; Proper Management of Labor by the Country Doctor, by Dr. A. E. Cook, of Randolph; Obstetric Forceps, by Dr. Andrew B. Somers, of Omaha; The Choice of Operations for the Restoration of the Pelvic Floor, by Dr. J. W. Bullard, of Pawnee City; Chronic Metritis, by Dr. Ewing Brown, of Omaha; Conservatism in Gynecology, by Dr. A. B. Anderson, of Pawnee City; Chronic Salpingitis, by Dr. Frank Park, of Omaha; "Symposium" on Extrauterine Pregnancy—(a) Clinical Picture and Treatment, by Dr. W. O. Henry, of Omaha; (b) Histology and Pathology, by Dr. E. C. Henry, of Omaha; A Simple Method of Hysteromyectomy by the Aid of a Dagger Clamp, by Dr. H. M. Hepperlen, of Beatrice; Suprapubic Prostatectomy, by Dr. A. I. McKinnon, of Lincoln; The Abortive Type of Typhoid Fever, by Dr. William R. Young, of Ansley; Pain in the Upper Abdomen—What It May Mean, by Dr. J. E. Summers, Jr., of Omaha; Something New in Antiseptic Procedure, by Dr. William B. Ely, of University Place; Some Incomplete and Some Wrong Diagnoses, by Dr. George Haslam, of Fremont; The Diagnosis of Cancer of the Stomach, by Dr. H. L. Alkin, of Omaha; The Laryngeal Affections of Singers, by Dr. H. B. Lemere, of Omaha; Smallpox, by Dr. Francis P. Dorsey, of Hartington; Indications for Operation in Mastoid Disease, by Dr. S. E. Cook, of Lincoln; Report of Two Cases of Leucæmia and Two Cases of Splenic Anæmia and Their Differentiation, by Dr. W. O. Bridges, of Omaha; Intestinal Obstruction, by Dr. R. D. Mason, of Omaha; Nephritis—Etiology and Treatment, by Dr. John Mills Mayhew, of Lincoln; Actinomycosis of the Lungs, by Dr. E. Fletcher Ingals, of Chicago; Trypanosomes and Disease, with Demonstration of Nebraska Specimens, by Professor Henry B. Ward, of State University; Cysts of the Anterior Mediastinum, by Dr. A. P. Condon, of Omaha; The Diagnosis of Hemorrhage from the Alimentary Tract, with Cases, by Dr. W. F. Milroy, of Omaha; Variation from Routine Necessary in Some Operations for Inguinal Hernia, by Dr. John Prentiss Lord, of Omaha; "Symposium" on Diabetes Mellitus—(a) Physiopathological Consideration, by Dr. I. N. Pickett, of Odell; (b) General and Special Etiology, by Dr. P. L. Gillispie, of Wymore; (c) Diagnosis—With Special Reference to the Præglicosuric Stage, by Dr. George H. Brash, of Beatrice; (d) Ocular Complications, by Dr. John I. McGirr, of Beatrice; (e) Nervous Phenomena, by Dr. C. P. Fall, of Beatrice; (f) The Precautions a Surgeon Should Take for Operating on Diabetic Subjects, by Dr. H. M. Hepperlen, of Beatrice; (g) Diabetic Treatment, by Dr. C. A. Love, of Beatrice; (h) Medical Treatment, by Dr. B. M. Deardorf, of Clatonia; Some Notes on Mastoiditis with Spontaneous Perforation in the Digestive Fossa, by Dr. F. S. Owen, of Omaha; Endocarditis—Its Etiology and Symptomatology, by Dr. C. W. M. Poynter, of Lincoln; Adhesions About the Sigmoid Flexure, by Dr. Harry H. Everett, of Lincoln; The Pharmacology of Antipyretics, by Dr. A. L. Muirhead, of Omaha; Upon the Treatment of the Individual Case in Appendicitis, by Dr. C. C. Allison, of Omaha; Diagnosis of Bright's Disease, by Dr. L. B. Pillsbury, of Lincoln; The Symptoms Which Demand Operative Interference in Intestinal Obstruction, by Dr. Charles O'Neil Rich, of Omaha; Chorea—Its Etiology and Treatment, by Dr. H. M. McClanahan, of Omaha; General Surgery, by Dr. H. C. Moore, of Omaha; Too Much Medicine, by Dr. J. Lue Sutherland, of Grand Island; Foreign Bodies in the Esophagus, and Foreign Bodies in the Larynx and Trachea, by Dr. Warwick M. Cowgill, of Lincoln; The Diagnosis of Gastric Ulcer, by Dr. H. J. Lehnhoff, of Lincoln; Plaster of Paris in the Treatment of Surgical and Traumatic Wounds of the Soft Parts, by Dr. H. Winnett Orr, of Lincoln; Diseases of the Accessory Sinuses of Nose, by Dr. D. C. Bryant, of Omaha; When and How to Operate for Prostatic Hypertrophy, by Dr. A. C. Stokes, of Omaha.

Pith of Current Literature

REVUE DE MEDECINE.

March, 1905.

1. Contribution to the History of Sexual Neurasthenia,
By FÉRÉ.
2. Menstrual Fever in Those Who Are Suffering with
Pulmonary Phthisis, By SABOURIN.
3. A Case of Angioma of the Carotid, By HARDOUIN.
4. Bronzing in a Case of Diabetes, By MARGAIN.
5. The Hypophysis (Pituitary Body) and the Pathogenesis
of Basedow's Disease, By SALMON.
6. The Rôle of Glycogenesis in Consumptive Diabetes,
By LÉPINE.

1. Contribution to the History of Sexual Neurasthenia.—Féré narrates the history of two peculiar cases in which there was a general condition of depression which may be regarded as a favorable preparation for neurasthenia. The latter condition resulted in the one case after a sexual storm and in the other after a fall from a ladder.

2. Menstrual Fever in Phthisical Women.—Sabourin in a lengthy communication concludes that this recurring fever in women who, in many instances, menstruate not at all or only very little, is not a matter of great importance, notwithstanding the monthly repetition of more or less pronounced congestive phenomena relating to the lungs. He was unable to discover that it had any bearing upon the development of tuberculous lesions. They may remain in bed or not during the existence of this fever, the same as if the sufferers were not tuberculous. For those who have a tendency to hæmoptysis it is better to remain in bed when the catamenial crisis is present, and remain there during its entire duration. Hæmoptysis almost always precedes the menstrual flow and is arrested after the flow has been established. In cases of dysmenorrhœa one may administer hot drinks, sinapisms, foot baths, hot applications to the abdomen, etc. Should hæmoptysis persist after the menstrual flow has occurred it may be treated by simply restricting the diet for twenty-four or forty-eight hours as a means of reducing the congestion. If amenorrhœa has supervened no treatment will be of much use, except that which will improve general nutrition.

5. The Pituitary Body and the Pathogenesis of Basedow's Disease.—Salmon considers this disease to be due to initial intoxication of the nervous centres, which gives rise to superactivity of the thyroid gland. The primary cause is functional derangement of the pituitary body, the internal secretion of which is essential to the nutrition of the nerve elements, and is an antitoxine for the nerve centres. It is also functionally related to the thyroid gland, so that disease in one is accompanied by disturbance in the other. Thus in acromegaly and in tumors of the pituitary body the thyroid undergoes change, and there is always hypertrophy of the pituitary body with myxœdema and goitre. Bruda found the pituitary body very small and hard in two autopsies after Basedow's disease, while in a third it was normal. This relationship furnishes an explanation of the

complex ætiology of Basedow's disease; it explains the emotional phenomena, the traumatisms of the head, the relations between disease of the nasal passages and exophthalmic goitre, etc. Further, post mortem investigations in cases of Basedow's disease are very desirable for the further study of its relationship to the pituitary body.

6. Glycogenesis in Consumptive Diabetes.—Lépine remarks that in most cases of diabetes there is a diminution of the glycolysis in the tissues. But in most diabetics the element of denutrition must also be considered. This occurs in spite of abundance of albumenoid and fatty food and in spite of the tolerance of such drugs as opium and antipyrine. The author believes that in such cases glycogen does not constitute the exclusive source of sugar. This was proved by experiments upon dogs in which the sugar in the blood was increased from a few milligrammes per litre to more than twenty centigrammes within half an hour. This increase occurred during the passage of the blood through the lungs, the dogs being narcotized with chloroform. The same result was obtained after administration of carbonic oxide, after venesection, etc. Other experiments as well as clinical experience have shown that diabetics should avoid a diet rich in albumenoids. One of the most recent suggestions as a diet for diabetics consists in the exclusive use of potatoes, the vegetable albumenoids replacing those from animal sources.

REVUE DE CHIRURGIE.

March, 1905.

1. Castration for Sexual Perversion, By FÉRÉ.
2. On the Entrance of Air Into the Veins During Surgical Operations, By DELORE and DUTEIL.
3. The Surgery of the Heart, By GUIBAL.
4. Gastrorrhagia in Simple Ulcer of the Stomach,
By TUFFIER and JEANNE.
5. Intestinal Hæmorrhage Following the Operations for Hernia, By SAUVÉ.
6. Contributions to the Study of Functional Impotence Consecutive to Traumatisms of the Joints,
By MALY and RICHON.

2. On the Entrance of Air Into the Veins During Surgical Operations.—Delore and Duteil advise puncture of the right auricle when the accident in question has occurred. This may be done by thrusting a needle attached to an aspirator into the third intercostal space of the left side, one centimetre and a half from the border of the sternum. This will enable one to avoid the internal mammary vessels. A layer of lung tissue may be penetrated, but this will do no particular harm. By doing this operation promptly it may result in saving life.

4. Gastrorrhagia in Simple Ulcer of the Stomach.—Tuffier and Jeanne propose the following indications for surgical interference in gastrorrhagia: 1. Ulcers limited to the different layers of gastric tissue. When it is easy of access and involves only the mucous layer the latter should be ligated en masse, and transmucous sutures passed. When it involves the entire wall of the stomach, resection by gastrectomy or pylorotomy should be performed, according to

the situation of the ulcer, and sutures passed in two layers. When it is difficult of access and involves only the mucous membrane, cauterization may be practised. When it involves the entire wall a row of ligatures should be passed from each extremity of the curvature, which is nearest the ulcer. 2. Ulcers which have gradually extended beyond the stomach, adhesions to neighboring tissues having formed. When there is no stenosis of the pylorus, and the ulcer is easy of access, the edges should be laid bare, with or without curettage, and the wound sutured. If it is difficult of access the tissues at a distance from the wound must also be ligated. When there is stenosis of the pylorus gastroenterostomy should be performed, careful hæmostasis being observed. 3. Ulcers which are multiple and disseminated. Gastroenterostomy associated if necessary with direct hæmostasis. 4. Ulcers which cannot be discovered; gastroenterostomy is indicated.

FORTSCHRITTE DER MEDIZIN.

March 1, 1905.

1. Concerning Intermittent Lameness, By ZESAS.
2. The Morphology of Carcinoma and the Question of Its Parasitic Origin, By ORTH.
3. The Intravenous Administration of Salicylic Acid, By MENZER.

2. **The Morphology of Carcinoma and the Question of Its Parasitic Origin.**—Orth remarks that the only peculiarity of cancer consists in the presence of epithelial cells which appear in uninterrupted series from preformed epithelium. From a scientific standpoint, therefore, every cancer should be designated an epithelioma. To differentiate it from other epithelial new growths it can be designated as a malignant, destructive, or heterotopic epithelioma. There is no metaplasia of connective tissue cells or other cells into cancer cells and the stroma of cancer has no peculiar significance. Two groups of heterotopic epitheliomata can be distinguished: 1. Those in which there is a typical arrangement of the cancer cells, including adenomata and caneroids; 2. those in which the cells are arranged atypically and which may receive the general name cancer. Inasmuch as parasites constitute a feature in suppuration, tuberculosis, etc., one may be justified in concluding that this must also be the case in cancerous new growths. If parasites do indeed form a feature of cancer they must differ from those which occur with suppuration, tuberculosis, etc., because they must stand in the closest relation to the cancer cells. But the occurrence of such parasites has not yet been demonstrated. In experiments which have to do with the transmission of tumors, the question concerns only transplantation, the formation of a secondary tumor and metastasis. It is not necessary to assume the presence of parasites; on the contrary, various explanations are possible for that which occurs in connection with cancer. The unsystematic, heterotopic proliferation of epithelial cells can be very well comprehended without resorting to the hypothesis of parasites.

3. **The Intravenous Administration of Salicylic Acid.**—Menzer informs us that the methods of

administering salicylic acid, by the mouth, rectum, and inunction, have been reinforced by Mendel's proposal of intravenous injection. His solution consists of sodium salicylate 17.5 grammes, caffeine 2.5 grammes, distilled water to 100 grammes. Two cubic centimetres of the mixture are injected, containing 0.35 grammes of sodium salicylate. Rubens has tried this method in 60 cases. An illustrative case is that of a man who had inflammatory rheumatism, with fever, swollen joints, and great pain. Five minutes after the above solution was injected the swelling disappeared from his joints and his pain left him. The pain returned, however, in half an hour. Burgsch, who has also tried this method, reports that it is very painful, and could not well be introduced into general practice. It has no advantages in the treatment of acute articular rheumatism, and in the mild subacute and chronic cases it is less effective than other measures.

March 10, 1905.

1. The Use of Thiol in Dermatology, By LEREDDE.
2. Concerning Intermittent Lameness, By ZESAS.

1. **The Use of Thiol in Dermatology.**—Leredde states that no specific effect is to be attributed to thiol. He knows of no pruriginous disease, however, in which it may not be used with advantage. He has used it for pruritus vulvæ, prurigo, urticaria, and lichen planus. It may be employed as long as the changes in the skin are superficial. In chronic pruritus it will relieve, but not cure. A cure may be obtained from radiotherapy. It has been used advantageously for acne and for burns. It has also given good results in the treatment of pityriasis rosea.

March 20, 1905.

1. Concerning the Diagnostic Significance of Certain Skin and Tendon Reflexes, By ROTHMANN.
2. Concerning Local Exsanguination and Local Anæsthesia, By MÜLLER.

2. **Concerning Local Exsanguination and Local Anæsthesia.**—Müller prefers the use of cocaine mixtures for local anæsthesia to eucaïne B, combined with adrenalin, though the latter are believed to be less poisonous. Cocaine does not interfere with the efficiency of adrenalin and suprenalin. Eucaïne B. and tropa cocaine modify the contracting power of suprenalin and adrenalin so that stronger solutions of the latter are required when combined with the former. Cocaine combined with suprenalin has been found very efficient in operations on the female genital organs. Suprenalin when injected into the female genital organs may produce poisonous symptoms. Stovaine is also recommended as a safe and efficient local anæsthetic.

ZENTRALBLATT FUER GYNAEKOLOGIE.

March 11, 1905.

1. A Case of Acute Œdema of the Cervical Lips During Pregnancy Due to Coprostitis, By L. SEITZ.
 2. Prevention of Bladder Disturbances After Gynaecological Operations, By GUTERD.
1. **Acute Œdema of the Cervix.**—Seitz reports the case of a multipara in whom a midwife incised the prolapsed œdematous lips of the cervix,

mistaking them for the membranes. Severe hæmorrhage followed. The woman's rectum was loaded with feces and their removal was promptly followed by a subsidence of the œdema. Recovery followed.

2. The Bladder After Operations.—Gutbrod advises the use of a permanent rubber catheter for five to eight days after hysterectomies, Alexander's operations, and colporrhaphies for the avoidance of cystitis and bladder irritations. The plan has worked well in his hands.

March 18, 1905.

1. Facial and Hypoglossus Paresis Following Spontaneous Births, By A. STEIN.

1. Facial Paresis After Normal Births.—Stein reports a birth in a primipara which lasted nearly twenty-two hours. The child presented a doughy swelling over the left mastoid bone which was regarded as a hæmatoma. Facial and hypoglossus paresis were present, the former disappearing in eight days, the latter a few days later. The author thinks that an intracranial hæmatoma must have existed in addition to the extracranial one to account for the symptoms.

BERLINER KLINISCHE WOCHENSCHRIFT.

March 6, 1905.

1. Relations Between Diabetes and Surgical Operations (*To be concluded*), By KAREWSKI.
2. Influence of Temperature of 55° C., Upon Agglutination in Ficker's and Widal's Reaction, By K. SADLER.
3. Macroscopic Agglutination Test in Typhoid Fever, By P. AASER.
4. Cold in the Treatment of Skin Diseases, By M. JULIUSBERG.
5. Serous Meningoencephalitis of Nasal Origin, By J. HERZFELD.
6. Forensic Tests for Blood, By H. MARX.

2. Influence of Temperature on Widal's Reaction.—Sadler reports his experiments showing the favorable influence of a temperature of 55° C. in using Ficker's test for typhoid fever. The same temperature acts favorably on Widal's reaction both microscopically and macroscopically. Ficker's test is more reliable than Widal's, also at a temperature of 37° C., if carried out under the same precautions. At 55° C. Ficker's reaction is obtained more quickly than the microscopic Widal test at 37° C.

3. Agglutination Test.—Aaser eliminated in his numerous experiments all pseudoagglutinations in order to have absolutely perfect results. He shows that even without a thermostat reliable results can be obtained. He mixed toluol with the reagent so that it was no longer dangerous and can be used in this manner by the practising physician.

4. Cold in the Treatment of Skin Diseases.—Juliusberg has used carbonic acid gas in the treatment of skin diseases, the acid having a powerful freezing action, so that its dosage must be carefully regulated. He uses the gas by allowing it to act upon the skin for from thirty to sixty seconds, repeating it in a week if necessary. He has used the treatment in cases of acne, psoriasis,

syctic processes, ulcers of the leg, ulcerations due to the Röntgen rays, chancroids, lupus, and lupus erythematosides. In psoriasis and lupus the lesions seemed to get worse, but in lupus erythematosides there was a decided improvement, all but one of the nine cases treated being benefited.

5. Meningoencephalitis.—Herzfeld says that abscesses due to serous meningoencephalitis of nasal origin is difficult of diagnosis on account of the absence of focal symptoms. He reports such a case following an empyema of the frontal sinus. Unconsciousness and convulsions of the left half of the body were the principal symptoms. Trephining over the right half of the brain brought about a cure.

6. Forensic Blood Tests.—Marx reviews the methods at present in vogue giving special prominence to the precipitate test for differentiating human from animal blood. This method is based upon the specificity of the proteids of the species.

March 13, 1905.

1. Morphology of Cancer and the Parasitic Theory (*To be concluded*), By J. ORTH.
2. The Complement Contents of the Blood in Different Forms of Tuberculosis, By J. KENTZLER.
3. A Newly Observed Accompaniment of Paresis of the Peroneal Nerve, By H. HIRSCHFELD.
4. The Physiological Action of Sool Baths, By T. GROEDEL.
5. The Modern Treatment of Heart Disease, By E. DE RENZI.
6. The Relations Between Diabetes and Surgical Operations (*Continued*), By KAREWSKI.
7. Sunshine and Epidemics in 1904-5, By J. RUHEMANN.
8. Rapid Dilatation of the Cervical Canal, By STOECKEL.

2. Complements in the Blood.—Kentzler concludes from his experiments that since the complement contents of the blood in all forms of tuberculosis are identical with those contained in normal human blood, it is clear that the blood of tuberculous persons is endowed with a sufficient quantity of protective material. It is, therefore, fair to assume that the amboceptor undergoes such a qualitative change in the course of tuberculosis that despite the presence of a sufficient quantity of protective material, the destructive action of the tuberculous virus is not inhibited.

3. Paresis of the Peroneal Nerve.—Hirschfeld has noticed that if a patient suffering from paresis of the peroneal nerve is required to bend the foot dorsally, the action is much more limited with the knee extended than if the knee is simultaneously flexed. This phenomenon is present only to a slight degree in the early stage of repair, but increases with the restoration of the paralyzed muscles and finally disappears when a cure is established. The practical result of this observation is to institute active movements in cases of peroneus paresis, with the knee flexed, as the paretic muscles are thus capable of a more extensive dorsal flexion.

5. Modern Treatment of Heart Disease.—De Renzi, after referring to many well known facts, urges a systematic salicylic treatment in cases of acute articular rheumatism in the hope of avoid-

ing cardiac complications. Digitalis, he says, is contraindicated in cases with good compensation. The author strongly advises the use of passive movements even in uncompensated cases.

8. Dilatation of the Cervical Canal.—Stoeckel reviews the many opinions which have been given on the virtues and demerits of the Bossi dilator. He says the instrument can be used at any period of pregnancy even in primiparæ, with the cervical canal still intact and with the os entirely closed. The after effects—lacerations of the cervix, immediate hæmorrhage, inflammatory exudates, etc.—have been in no way lessened by care and skill in the use of the instrument. The author does not advise its use by general practitioners.

March 20, 1905.

1. Our Knowledge of the Origin of Malignant Neoplasms (To be concluded), By VON HANSEMAN.
2. The Function of the Sebaceous Glands and Their Relation to Fat Metabolism, By A. BUSCHKE and A. FRAENKEL.
3. The Action of Alcohol Upon the Change in the Pupillary Reaction, By H. VOGT.
4. Rectal Gonorrhœa in Infantile Vulvovaginitis, By K. FLÜGEL.
5. The Morphology of Cancer and the Parasitic Theory (Concluded), By J. ORTH.
6. Relations Between Diabetes and Surgical Operations, By KAREWSKI.
7. Origin and Treatment of Myopia, By HELBRON.

2. Function of Sebaceous Glands.—Buschke and Fraenkel show experimentally that physostigmine produces an excessive secretion from the meibomian glands in guinea pigs, possibly by direct action upon voluntary and involuntary muscle fibre. The histological and chemical examinations make it appear likely that even in animals primarily fat is excreted by the sebaceous glands and that the destruction of the cells of the glands is a secondary matter. Further physiological examination shows that under especially favorable circumstances the fat of the food can be excreted through these glands, although there is no analogy between this fact and similar excretion through the cecygeal gland of birds.

3. Alcohol and the Pupillary Reaction.—Vogt notes that in normal persons, alcoholic intoxication produces no change in the reaction of the pupils, yet in mentally diseased individuals small doses of alcohol cause a delayed reaction to light. In one case the pupils reacted unequally, while arteriosclerotic persons in general showed a change in the pupillary reaction. The other reflexes were affected similarly to those in healthy individuals. Chronic alcoholics showed the same pupillary changes, so that it is evident that alcohol can, in time, bring about such lesions. It follows that the reaction of the pupils to alcohol is a test as to the cause of unconsciousness in those cases in which this condition follows the indulgence in alcoholic liquors.

4. Rectal Gonorrhœa.—Flügel found and proved bacteriologically twenty per cent. out of fifty-six cases of vulvovaginitis to have rectal gonorrhœa. The most common mode of infec-

tion is by the entrance of pus into the rectum from the vaginal discharge. The treatment consists in the administration of suppositories of silver nitrate or the silver albuminates. The rectal secretion is always more quickly freed of gonococci than that of the vagina, since the rectum furnishes a poorer medium for the growth of the bacteria. The author advises careful observation in all cases of vulvovaginitis against rectal infection.

5. Parasitic Theory of Cancer.—Orth concludes a lengthy paper as follows: 1. The essential element of all cancers is the cancer cell, without which there can be no metastasis. 2. Parasites are not essential to the elucidation of metastases as cells, capable of growth, are sufficient to explain them. 3. There is no analogy between metastatic pus infections, tubercle tissue, or other granulomata and cancer, hence there can be analogous conclusion as to the parasitic origin of cancer. 4. The inoculation of a second individual with cancer does not require the parasitic theory in explanation, since it can be explained by a metastasis due to inoculated cells. 5. The present status of the parasitic theory of cancer is not sufficiently crystallized to form a scientific basis for this belief.

6. Diabetes and Surgical Operations.—Karewski says that in diabetics there are no characteristically peculiar symptoms after surgical procedures, although the greater the degree of glycosuria and the greater its resistance to influence by diet, the greater the chances of infection become. The patient's general constitution forms a criterion as to his ability to withstand operations. The author considers in detail the causes of coma after operation. He advises postponing operations on diabetics until the glycosuria has been reduced and the general condition improved.

7. Myopia.—Helbron considers the causes of myopia due to increase of the intraocular pressure in the posterior portion of the bulb, such as sewing by persons with a tendency to myopia, anatomical peculiarities in the eyes of myopics, etc. These conditions are due primarily to diminished resistance of the posterior portion of the myopic eye. The modern method of treatment is to correct fully far and near vision, but in high degrees of myopia and in elderly persons, under correction is necessary.

RIFORMA MEDICA.

March 18, 1905.

1. Further Researches on Serum Therapy in Syphilis, By A. RISSO and A. CIPOLLINA.
2. The Alleged Exaltation of Virulence in the Typhoid Bacillus, By C. P. GOGGIA.
3. The Horizons of Modern Surgery, By DOMENICO MORISANI.

1. Serum Therapy in Syphilis.—In a previous article Risso and Cipollina described the preparation of their serum against syphilis, and the experiments which they performed with this remedy. The serum is obtained from dogs that have been previously immunized by means of injections of the blood of syphilitic patients who were in the full tide of secondary syphilis. To this serum

they also added small amounts of the corpuscles of the same immunized animals, after dissolving these corpuscles by hæmolysis. This was done with the idea that a portion of the immunizing substances of an animal's blood is contained within the cells thereof, while the rest resides in the plasma. In this first article they reported eight cases of syphilis, of which six were cured and two were only slightly improved, inasmuch as treatment had just been begun. In the present articles the authors report that of five syphilitics with secondary manifestations that had been declared cured, three had no signs of the disease whatever since then, and have continued the treatment, while the other two patients, who had interrupted the treatment, had some recurrences. They found that the treatment was efficient in most cases of secondary syphilis, although ten, or more, injections were sometimes needed to cause improvement. In the second series of patients which is reported now, the serums used were more irritating and smaller doses had to be used. The larger doses of the less irritating serums were more efficient in the first series of cases. The results obtained by the authors with tertiary cases are of especial interest. They described two cases cured in the third stage, in the first report. The cases now reported are more severe forms of tertiary lesions. A typical case was one which occurred in a woman with an ulcerating gumma at her ankle. Simple applications of boric acid were made locally, and the serum was used internally. The ulcer rapidly healed. On the other hand, another ulcer on the forehead, which was treated by mercurial ointment, continued to grow worse, and had to be incised. The authors conclude that the serum acts favorably in both secondary and tertiary forms, and possibly in the initial parasymphilitic manifestations. The dosage and the manner in which the remedy is borne by patients vary in each case. Thus there are patients who bear five c.c. of the serum injected daily exceedingly well, while others develop local tenderness and pain, or urticaria, or febrile symptoms after the injections.

2. **The Alleged Increase in Virulence of the Typhoid Bacillus.**—Goggia, of Maragliano's laboratory, reports the results of his experiments on animals, with a view of determining whether the typhoid bacillus is identical with or at least related to the colon bacillus. He injected a culture of a typical Eberth bacillus into the peritonæum of two guinea pigs. After these animals died the peritonæum was opened, and a culture was made of its contents. This culture was inoculated into a second pair, thence into a third, etc., until a sixth pair was reached. The bacillus recovered by culture from the sixth inoculation was a typical bacillus coli communis. The guinea pigs in each succeeding pair died more and more rapidly after the injection of the same amount of culture. The bacillus recovered from the sixth pair had all the biological characters of a colon bacillus, and did not become agglutinated by typhoid serum except in a very slight degree. This bacillus was not the original typhoid bacillus injected into the first pair, but a colon bacillus, which had entered the

intestines of the first pair and penetrated into the peritonæum, as this bacillus can do, according to the author's experiments detailed in this article. The value of such experiments as that described, namely, of the transmission of a culture through several animals by peritoneal injections is very doubtful, and they do not decide the question as to the possibility of the typhoid bacillus being enhanced in virulence or identical with the bacillus coli. To show how fallacious experiments of transplantation are, the author injected into the peritonæum of three guinea pigs three different cultures. Into the first animal he injected a classical typhoid culture; into the second, one obtained from the peritonæum of the first; and into the third, a culture from the peritonæum of the second. The bacillus obtained from each of these three animals had all the characters of the bacillus coli, and, besides, did not become agglutinated with a typhoid serum, which agglutinated the typhoid bacillus in the proportion of 1:100. The experiments quoted, therefore, cannot be accepted in support of the alleged increase in virulence of the typhoid bacillus when transmitted through several animals.

ROUSSKY VRATCH.

March 5, 1905.

1. Enormous Pendulous Lipoma of the Right Labium Majus, By V. V. MAKSIMOFF.
2. Attempts at Inoculating Gonococci in Small Laboratory Animals and Experiments with Serum Therapy, By M. N. MOSKALEFF.
3. On the Secretive Function of the Parotid Gland in Man (Concluded), By E. A. ZHERBOVSKI.
4. Syphilis of the Lungs, By S. B. BERMEL and N. B. SOLOVIOFF.

1. **Large Lipoma of the Vulva.**—Maksimoff reports the case of a woman aged 19 years, unmarried, who had a lipoma of enormous size on the right labium majus. The tumor was pendulous and swung between her legs, reaching down to the knees. Removal was indicated, especially because the tumor had begun to ulcerate under the influence of external causes, such as friction, wetting with urine, etc. The growth had taken a number of years to reach this size. When removed it weighed about eight pounds, and was found to be a true lipoma.

2. **Inoculation and Serum Therapy of Gonococcus.**—Moskaleff reports the results of a series of researches on animals with inoculation of the gonococcus, and with the making of a protective serum against this germ. The best media for the growth of the gonococcus are those of Wassermann, Wertheim, and Kiefer, the last being most conveniently prepared. The Kiefer medium contains pleuritic exudate mixed with agar-agar, and glycerin. Gonococci proved pathogenic in rabbits on being injected either subcutaneously or into the peritonæum. These germs were also pathogenic in white mice, producing fatal infections when injected into the peritonæum. White mice are probably the most convenient animals for experimenting on the pathogenic action of the germ. The action of the gonococcus on the various tissues of the body depends upon the activ-

ity of the gonococccotoxine. The latter acts chemiotactically, and produces a sterile suppuration in some tissues, while in others it acts on the vessels, and cytolytically on the cells, and produces transparent exudates. (This is the case in the peritoneum.) Serum of rabbits rendered immune by the inoculation of gonococci proved to a certain extent a curative and preventive agent, but further experiments are needed to give more definite results.

2. **Parotid Gland.**—The function of the parotid gland is the subject of a scientific research by Zherbovski. He found that the secretion of the gland varies in amount and quality according to the stimulus given by contact with various substances in the mouth. The amount of secretion of the parotid varies as the square root of the amount of stimulant applied to the mouth. Chewing has much to do with the rapidity of the secretion from the parotid, and the saliva is not only more abundant, but more viscid when mastication is vigorous and prolonged. When food is chewed on one side the corresponding parotid gland works more than the opposite gland, while when chewing goes on both sides both glands work equally. The alkalinity of the saliva is in porportion to the amount of ash therein. As the amount of ash increases, and as the rapidity of the secretion is enhanced, the alkalinity grows more marked. The digestive power of the saliva is proportionate to the amount of organic matter therein. The digestion of starch by the parotid secretion, after it reaches the stomach, is possible in proportion to the alkalinity of the saliva. The action of ptyalin in the stomach is only possible during the beginning, and the final stages of digestion. At the acme of gastric digestion, when the free hydrochloric acid is abundant, the action of the saliva is only possible when there are large amounts of highly alkaline saliva in the stomach. The influence of saliva in the digestion of proteids reduces itself to a dilution of the hydrochloric acid of the gastric juice, and in disease makes hypoacidity worse, while it tends to make hyperacidity less severe.

3. **Syphilis of the Lungs.**—Bermel and Solovioff present two cases of pulmonary syphilis, both in adults of middle age. The clinical picture of pulmonary syphilis is very variable, and depends entirely upon the degree of anatomical lesions, which are present in the lungs. In both the cases reported, the disease began with abscesses in the lungs. There was no possibility of a mistake for tuberculosis, as often happens in such cases. These abscesses were gummas that had suppurated under the influence of secondary infections with streptococci. The authors think that the occurrence of secondary infections in syphilitic pneumonias is the chief cause of the variable clinical symptom of these affections. The fever is one of the signs of such a secondary infection. The slow development of the disease, without any characteristic changes locally in the lungs, denotes its syphilitic character, as does, of course, the history of syphilis, or the presence of syphilitic lesions elsewhere in the body. No char-

acteristic location can be given to the syphilitic lesions occurring in the lungs, but the presence of a focus in the middle right lobe is quite suggestive. Cough and expectoration, with or without blood, are not necessarily accompaniments of pulmonary syphilis, but may aid in the diagnosis when present. The loss of flesh and strength and the sweats are rather effects of the complications, than of the disease itself. The prognosis is quite favorable, thanks to the possibility of applying specific treatment.

BOSTON MEDICAL AND SURGICAL JOURNAL.

April 20, 1905.

1. A Method of Producing Ether Narcosis by Rectum, with the Report of Forty-one Cases,
By JOHN H. CUNNINGHAM, JR., and F. H. LAHEY.
2. Serum Treatment in Multiple Infectious Arthritis,
By E. G. BRACKETT.
3. The Communicability of Cerebrospinal Meningitis,
By E. M. BUCKINGHAM.

1. **Ether Per Rectum.**—Cunningham and Lahey report in detail each one of the forty-one cases in which ether narcosis was produced by the administration of ether vapor per rectum. A special apparatus is necessary in order that irritation of the bowel may be avoided. It can easily be made with a little glass and rubber tubing and a rubber bulb for producing air pressure. Pirogoff, in 1847, was probably the first who attempted to administer ether in this fashion. The present experiments are the first which have given promising results. The authors believe that this method of producing narcosis has a distinct place in practical medicine.

2. **Infectious Arthritis.**—Brackett reports four cases of multiple infectious arthritis treated by injections of antistreptococcus serum. The joint manifestations, in the class of cases suited to this form of treatment, are due, probably, to the action of toxins rather than to the actual invasion of the joints by the offending microorganisms. The author concludes that the use of the serum when effectual is apparently only to cut short the acute stage. It has no effect on the deformity or the stiffness of the joints, except to diminish that which is caused by the sensitiveness. The remaining deformity and limitation of motion are the results of the adhesions and contractions, and must be treated by the usual means employed to relieve this condition when existing from any cause after the inflammatory process has subsided.

3. **Meningitis.**—Buckingham asserts that living in the same room and breathing the same air with patients ill with cerebrospinal meningitis is not in itself dangerous. However else the disease is spread, it is not spread by what is commonly understood as contagion. These conclusions are based on the fact that during eight years there have been treated 110 cases of meningitis in the Children's Hospital, Boston, and that during that time not a single case has originated there. The meningitis cases are not isolated, but are treated in the general wards, and are not the subjects of special precautions.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

April 22, 1905.

1. Laboratory Diagnosis of Variola. By R. L. THOMPSON.
2. Large Carcinomatous Tumor of the Liver. Removal Seventeen Months After Nephrectomy for Carcinoma of the Left Kidney. Temporary Recovery,
By THOMAS S. CULLEN.
3. Reclination of the Lens: Under Certain Conditions a Justifiable Operation, By F. T. ROGERS.
4. Eye Strain, By LEWIS S. DIXON.
5. Some Fallacies in the Agglutination Tests; a Plea for the Employment of a More Uniform Technic,
By OSKAR KLOTZ.
6. The Scintillating Scotoma or Transient Functional Hemipia, By CHARLES J. KIPP.
7. Intestinal Perforation Complicating Typhoid Fever,
By GEORGE L. HAYS.
8. The Extraction of the Intracellular Toxine of the Colon Bacillus, with a Preliminary Statement Concerning Its Physical and Chemical Properties,
By SYBIL MAY WHEELER.
9. Local Anæsthesia in Major and Minor Operations on the Ear, as Observed in Professor Politzer's Clinic in Vienna,
By GEORGE PAUL MARQUIS and OSCAR H. KRAFT.
10. Pus Tubes in the Male and Their Surgical Treatment,
By W. T. BELFIELD.
11. Immunity. Chapter XIII.

1. **Variola.**—Thompson describes a method of making a laboratory diagnosis of variola from a small skin snipping in an average time of three hours. The specimens to be examined must be fixed in acetone and imbedded in paraffin. Hæmatoxylineosin staining gives the best results, though other stains will at times answer. The diagnosis is based on a specific histological picture and on the presence of cytoplasmic and intranuclear bodies.

2. **Carcinoma of the Liver.**—Cullen reports his own case in minute detail. He reviews the various methods that have been employed and suggested for performing amputations of portions of the liver, and gives a table of seventeen cases of liver resection reported since 1899. The statistics up to this time have been collected by Keen. It is not feasible to profitably condense the paper which deals chiefly with operative techniques.

3. **Reclination of the Lens.**—Rogers concludes that the operation of reclination may be justifiable: (1) On the aged and infirm or those suffering from exhaustive diseases. (2) When there is non-curable infection of the conjunctiva or lacrimal sac. (3) When one eye has been lost by suppuration or hæmorrhage following operation and a similar result is feared. (4) In obstinate bronchitis. (5) In fluid vitreous with tremulous iris. (6) In the insane or unmanageable patient. (7) In the very deaf where the assistance of the patient cannot be secured.

7. **Intestinal Perforation.**—Hays reports twelve cases of intestinal perforation occurring during typhoid fever, and which came to operation. These, added to seven cases already reported, give a recovery percentage of 42.10. The author lays much stress on the following details of operation: (1) The bowel at the site of the per-

foration should be anchored to the peritonæum at the upper angle of the wound through the belly wall. (2) The peritoneal cavity should be thoroughly flushed with salt solution. (3) Drainage to the bottom of the pelvis. (4) The Fowler position.

10. **Pus Tubes in the Male.**—Belfield holds that an epididymitis following prostatic pus infection, whether gonorrhœal or other, is usually suppurative; pus tubes are quite as common in the male as in the female; hence the rational treatment of such acute epididymitis should frequently be surgical, i. e., it should include the evacuation of pus by incision.

MEDICAL RECORD.

April 22, 1905.

1. Visual Function the Cause of Slanted Handwriting; Its Relation to School Hygiene, School Desks, Malposture, Spinal Curvature, and Myopia,
By GEORGE M. GOULD.
2. Simple Ulcer of the Stomach and Its Surgical Treatment,
By JOHN J. McGRATH.
3. Erysipelas with an Excessive Production of Fibrin,
By ROLFE FLOYD.
4. An Unusual Case of Bradycardia,
By JULIUS H. COMROE.
5. Acute Posterior Periurethral Abscess,
By FERDINAND C. WALSH.
6. Report of an Interesting Case, By E. B. VAN ARSDEL.

1. **Visual Function.**—Gould devotes his paper to a very methodical condemnation of slant writing, school desks, and "recommended" malpostures for writing and reading. He explains how an untold list of evils follows in the wake of our wretched habits. Vertical writing, a desk whose top slants at an angle of about thirty degrees and a special penholder, will free the race from a number of ills. "It has been found that from 50 per cent. to 64 per cent. of school children are sickly or below a desirable form of health. I do not think it is an exaggeration to say that the ills of 50 per cent. of these hygienically subnormal children and students are due to the morbid postures compelled by the present false methods of writing and reading. Of the remaining 50 per cent., a full half are directly caused by the eyestrain of ametropic eyes. Headache, 'weak eyes,' migraine, anorexia, dyspepsia, and many types of denutrition, spinal curvature, insomnia, 'nervousness,' many cases of chorea and epilepsy, despondency and frequent psychic disorders, truancy, immorality, etc., almost any form or kind of functional disease—all these, and the denutrition that follows the ground for the incoming of infectious and terminal diseases—all of these are, or may be, the clear consequences of eyestrain. Only proper and scientific spectacles can extinguish these evils. But without glasses they are tremendously increased and intensified by the morbidities of posture engendered by the present school desks and methods of writing and reading. A revolution is demanded by an enlightened hygiene in school furniture and methods of writing and study. It is the most profound and crying reform of the day, a matter of national and evolutionary importance almost overtopping all others."

2. **Ulcer of the Stomach.**—McGrath writes a very complete text book article on ulcer of the stomach from the surgeon's point of view. The indications for surgical intervention are clearly given and the best adapted operations for specific conditions are reviewed.

5. **Periurethral Abscess.**—Walsh gives the following description of what he considers the best way of treating acute posterior periurethral abscesses of gonorrhœal origin: The patient being prepared as for an ordinary external urethrotomy, an incision is made in the perineal raphe down to the urethra, evacuating in this way any pus met with en route. The urethra is then freely opened and an exploration is made with the index finger which readily detects the presence of pus cavities and easily cures them. After exploring as far back as the bladder, and evacuating all cavities, this viscus should be thoroughly flushed with hot boric acid solution, and a full sized fenestrated rubber catheter inserted and secured in position through the urethral opening. Subsequent treatment should consist in washing the bladder twice daily through the catheter, which should first be removed, cleansed, and then reinserted.

MEDICAL NEWS.

April 22, 1905.

1. Alcohol as Food, By RUSSELL H. CHITTENDEN.
2. Alcohol in Disease, By GEORGE L. PEABODY.
3. The Health of the Nation, By WALTER WYMAN.
4. The Health of the Port of New York, By ALVAH H. DOTY.
5. What the State of New York is Doing for the Insane, By FREDERICK PETERSON.
6. Abdominal Nephrectomy, with Illustrative Cases, By NATHAN JACOBSON.

1. **Alcohol.**—Chittenden asserts that it is undoubtedly true that alcohol in moderate quantities may serve as a food, i. e., it can be oxidized with the liberation of heat and work. It may, to some extent, take the place of fat and carbohydrates, but is not a perfect substitute for them, and for this reason: Alcohol has a pharmacological action that cannot be ignored. It reduces liver oxidation. It therefore presents a dangerous side wholly wanting in carbohydrates and fats. The latter are simply burned up to carbonic acid and water, or are transformed into glycogen and fat, but alcohol, though more easily oxidizable, is at all times liable to obstruct, in some measure at least, the oxidative processes of the liver, and probably of other tissues also, thereby throwing into the circulation bodies, such as uric acid, which are inimical to health: a fact which at once tends to draw a distinct line of demarcation between alcohol and the two non-nitrogenous foods, fat, and carbohydrate. Another matter must be emphasized, and it is that the form in which alcohol is taken is of importance. Port wine, for instance, has more influence on the amount of uric acid secreted than an equivalent amount of alcohol in some other form. To conclude: As an adjunct to the ordinary daily diet of the healthy man alcohol cannot be considered as playing the part of a true non-nitrogenous food.

2. **Alcohol.**—Peabody reviews briefly the different use, both local and general, to which alcohol has been put in medicine. Its chief and most important use is internally. Unbiased clinical experience seems to justify the belief that in alcohol we have still the best means of stimulating the heart and thus increasing a low blood pressure in many pathological states. Necessity for its use in this way may arise both in conditions of primary weakness or syncope, and in enfeeblement due to acute febrile disease. In general it is not unusual to see numerous obvious beneficial effects follow its judicious administration. The tongue becomes less dry, the pulse becomes slower and fuller, the skin more moist, the wakefulness and delirium less marked, the powers of digestion and assimilation improved.

4. **Health of the Nation.**—Wyman lets statistics alone and confines himself to the general consideration of the various means, national, State, and local, by which the health of the nation is kept what it is and on which its future must depend.

4. **The Port of New York.**—Doty recounts the methods employed at the New York Quarantine Station to guard the city against the importation of such diseases as yellow fever, bubonic plague, cholera, typhus fever, and smallpox. In general it may be said that if the actual sufferers from a disease can be isolated the danger of a disease spreading is reduced to zero. The transmission of disease by means of the clothing of non-diseased attendants upon the sick is an almost unheard of occurrence.

6. **Abdominal Nephrectomy.**—Jacobson reports four personal cases of abdominal nephrectomy. He asserts that the abdominal route is not employed as often as it should be, and its mortality is not as high as has been taught. In general, the author advises that the abdominal route should be selected when the tumor is large, and when firm adhesions are to be expected.

AMERICAN MEDICINE.

April 22, 1905.

1. Some Remarks on Physical Diagnosis: 1. Transmanual Auscultation. 2. Ulnar Palpation, By DAVID RIESMAN.
2. Remarks on the Destructive Skin Diseases, Epithelioma, Lupus Vulgaris, and Syphilis, By HENRY W. STELWAGON.
3. Cholecystitis, By HOWARD LILIENTHAL.
4. A Study of Homogenized Cultures of Tubercle Bacilli, By RANDLE C. ROSENBERGER.
5. Typhoid Fever in Relation to the Urban and Rural Population of the United States, By SENECA EGBERT.
6. A Cure by Operation of an Intractable Pronated Foot, in Which the Head of the Astragalus Had Been Abducted and Fixed in This Position by Bone Union at the Astragalofibular Articulation, By MICHAEL HOKE.
7. Spontaneous Combustion, By JOHN KNOTT.

1. **Physical Diagnosis.**—Riesman asserts: (1) When it is difficult to time a heart murmur it will facilitate matters if some fingers or the hand are interposed between the bell of the stethoscope

and the patient's chest. The Bowles stethoscope gives the best results in this method of auscultation. (2) Palpation of the intercostal spaces is best accomplished by using the ulnar aspect of the hand.

2. Destructive Skin Lesions.—Stelwagon's remarks concern epithelioma and syphilis chiefly. The diagnosis and medicinal treatment of epithelioma is quite minutely covered. For epithelioma the author recommends, when surgery is refused, cauterization with caustic potash or a two or three days' application of pyrogallol salve, 33 per cent., or arsenical paste 33 to 50 per cent. Lupus is rare, much rarer than is generally supposed. Many of the cases diagnosed and reported in the journals as cases of lupus are in reality cases of syphilis. Therefore, if you are not a dermatologist, when you have a case which you are sure is lupus play mercury and the iodide of potassium and you will probably make a reputation.

3. Cholecystitis.—Lilienthal advises removal of the gall bladder in all cases of cholecystitis which come to operation. The reason for this advice is that it is impossible always to tell how much of the gall bladder is necrosed and probably not a few of the deaths following cholecystostomy are due to perforation of the gall bladder. The general advice regarding treatment follows: "The pain in the beginning of cholecystitis is usually so severe that opiates must be administered. Poulting and calomel should be the next steps. No food should be administered by the mouth, but small quantities of hot water or weak tea without milk may be given. If the patient's general condition is worse at the end of the first twenty-four hours, he should be seen by a surgeon, and I would here remind you that cholecystectomy is apt to be easier in the acute stage when the parts are softened by œdema than in chronic cases with tough, cicatricial adhesions. Judging by my own work, I should pronounce the operation of cholecystectomy more difficult, but safer than that for appendicitis of an equally severe type, and I believe that there is far less to be gained by waiting for the interval."

BRITISH MEDICAL JOURNAL.

2. Cases Illustrating Alternative Operations for Intestinal Obstruction, By A. E. BARKER.
3. Removal of Gall Bladder from a Woman Aged Seventy-five Years, By A. W. ADDINSELL.
4. New Methods of Studying Affections of the Heart, By J. MACKENZIE.
5. Obliterative Arteritis, Leading to Gangrene of Extremities in Otherwise Apparently Healthy Men in the Prime of Life, By E. MICHELS and F. P. WEBER.
6. The Incidence and Effect of Some Diseases on Others, By J. R. CHARLES.
7. The National Importance of the Thorough and Systematic Removal of Adenoids in Childhood, By G. C. WILKIN.
8. A Fatal Case of Acute Mercurial Poisoning, By E. S. SUGDEN.

9. A Case of Acute Strychnine Poisoning in a Child: Recovery, By J. R. POOLER.
10. The Correct Anatomical Form of Bicycle Pedals, By R. A. LUNDIE.

1. Ulcer of the Stomach.—Moynihan considers the various conditions which may arise in the following order: 1. The perforation of gastric or duodenal ulcer. 2. The occurrence of hæmorrhage in gastric or duodenal ulcer. 3. Chronic ulcer. 4. Hourglass stomach. In acute perforation the ulcer gives way suddenly and completely, and the stomach contents escape into the general peritoneal cavity. In subacute perforation the ulcer gives way almost as suddenly, but owing to the small size of the hole, to the emptiness of the stomach, to the plugging of the opening by an omental flap, or to the speedy formation of lymph which acts as a plug. In chronic perforation the ulcer has slowly eaten its way through the stomach coats and a protective peritonitis has had time to develop at its base. It occurs more frequently on the posterior surface of the stomach and the resulting perigastric abscess is recognized as "subphrenic." Recovery from all these forms of perforation is possible under medical treatment alone, but the acute form is almost invariably fatal. But even in the recovered cases surgical treatment is called for in a later stage, perhaps because of perigastric adhesions which hamper the action of the stomach, perhaps because an hourglass stomach is formed from constrictions. This is an argument in favor of instant operative treatment. The author has operated in twenty-two cases of perforating gastric or duodenal ulcer. There were fourteen recoveries—63.6 per cent. The ages of the patients varied from 17 to 44 years; 15 of the patients were women, but of the 7 duodenal cases, 4 were in men. In every case the patient had suffered from symptoms referable to the ulcer for varying periods, and in the majority of cases there had been no increase in the severity of the symptoms during the few days preceding perforation. In subacute cases it is most necessary to cleanse as thoroughly as possible, as the amount of lymph greatly exceeds that seen in acute cases. The cause of death in six cases was shock—in one empyema, and in one subphrenic abscess. Hæmorrhage from gastric ulcer may be divided into four groups: (a) latent or concealed, and always trivial; (b) intermittent, spontaneous, but in moderate quantity—the patient's life is never in danger, though anæmia is persistent; (c) occurring after a warning exacerbation of chronic symptoms—rapidly repeated, abundant, and persistent—if not unchecked it is often the cause of the patient's death; and (d) instant, overwhelming, and lethal. The only character that the hæmorrhage should possess to warrant the performance of an operation is recurrence; recurrence, too, at intervals which, becoming gradually curtailed, do not allow the patient to make up in the interval the ground which he loses in the attack. Of 22 patients operated on for the arrest of hæmorrhage, 19 recovered. Excision of the ulcer alone was done in one case, excision of the ulcer followed by gastroenterostomy in three cases, and in eighteen gastroenterostomy alone. In no

case was there hæmorrhage after the operation. For chronic ulcer of the stomach the author has operated 153 times, with 2 deaths. Gastroenterostomy was done in all. Twenty cases of hour-glass stomach were operated in with three deaths; gastroplasty was done in seven cases and gastroenterostomy in five.

5. **Obliterative Arteritis.**—Michels and Weber report a case of obliterative arteritis occurring in a Jew aged 39 years. The right leg had been amputated for gangrene some years previously, and when seen there was gangrene of the left big toe. This was removed, but the wound did not heal, so the leg was amputated below the knee, and recovery was uneventful. The lumen of the popliteal artery was found to be completely obliterated at the site of amputation. The authors have previously reported two similar cases, both occurring in Jews. The disease occurs almost exclusively in the male sex and the lower extremities are chiefly affected. It is possible that both poor or unwholesome food (ergotism is, of course, unknown in England) and racial factors may play a part in the ætiology.

6. **Coincidence of Diseases.**—Charles deals with the incidence of secondary infections in chronic disease. The most frequent infective organisms are the pyogenic cocci, the pneumococcus, and the tubercle bacillus. Of 152 fatal cases of chronic nephritis, 52, or exactly one third, succumbed to the results of secondary infections, including lobar pneumonia, inflammations of the serous membranes, and tuberculosis. Uræmia was the cause of death in sixty-six per cent. of the cases. To cirrhosis of the liver must be assigned the worst place as acting as a predisposing factor for the entrance of pathogenic organisms. Of 45 cases over 44 per cent. died of secondary infections. The reaction of the body in the presence of these chronic diseases is often extremely defective, both against the organisms and their toxins. Nineteen per cent. of the cases classed as primary arteriosclerosis died from pneumonia. Over 15 per cent. of the deaths which occurred among 109 subjects of chronic valvular disease were due to secondary infection. Pneumococcal infections were 14 times more common than tuberculous infection—thus bearing out the old idea that valvular heart disease and tuberculosis are antagonistic. The marked incidence and virulence of pulmonary tuberculosis in diabetes is well known. Many diseases modify the manifestations of epilepsy—among them may be mentioned measles, malaria, anthrax, pneumonia, and erysipelas. Well marked antagonism exists between pulmonary tuberculosis and leucæmia—but the reverse obtains with respect to chlorosis and phthisis. Cancer favors the invasion of the body by tubercle bacilli, but is inimical to the spread of the disease. As regards infectious diseases the chemical products of organisms, and also the bacteria themselves, may modify very profoundly the effects of others. Scarlet fever favors the onset of diphtheria, the converse obtaining also. Scarlet fever and enteric rarely occur together; scarlet fever also abolishes the characteristic whoop of whoop-

ing cough. The relationship of chorea and rheumatism is now well recognized—they can hardly be spoken of as two diseases.

1. **Diabetes.**—Bosanquet, in the first of his Goulstonian lectures on diabetes, begins with a short historical sketch of the disease, and then goes on to its definition. An important division in the subject in this regard, is the recognition of two forms or stages of diabetes mellitus: 1. The *alimentary* form, in which the sugar which emerges in the urine is apparently derived entirely from the carbohydrate materials contained in the food. 2. The *composite* form, in which some of the sugar is formed by breaking down of the tissues of the patient. In the first stage of diabetes the glycosuria is often only alimentary—an apparent inability to assimilate much carbohydrate food, and it is only in the later stages that the tissues actually break down into sugar. Sugar is not a poison, but in small quantities is a normal constituent of the blood. The internal formation of sugar must be looked upon as the essential characteristic of the disease. Glycosuria presupposes glycohæmia. An important cause which may determine the onset of diabetes is alcoholism; in this connection importance has also been attributed to tobacco. The influence of heredity is now more fully recognized than formerly; with it must be classed the racial incidence of diabetes, the disease being most common among the Jews and Oriental peoples. There is little evidence pointing to an infective cause of diabetes—i. e., that it is the direct effect of a toxine formed by a pathogenic bacterium. The action of syphilis in causing diabetes is probably due to the production of a pancreatitis. Overwork and exhaustion may apparently produce the disease—also sudden shock and excitement. Injuries to the head are more often followed by temporary glycosuria than by lasting diabetes, and experimentally many varieties of injury to the nervous system may produce glycosuria. Glycosuria is also common among the insane. As regards the morbid anatomy of diabetes, too much attention has been paid to the phenomena of glycogenesis and to the theory that

the liver is normally a distributor of sugar to the rest of the body. At present this is an unverified hypothesis. Post mortem two main changes are found in the liver. In most cases the organ is slightly enlarged, firm in consistence, and hyperæmic. In some it is distinctly fatty. As regards the kidneys it seems established that they merely eliminate from the blood the sugar which is poured into it from elsewhere. There is little or nothing to connect diabetes with gastric disorders, or with diseases of the skin, although psoriasis and xanthoma are said to be specially related to it.

2. **The Spread of Cancer.**—Handley in his first Hunterian lecture discusses the dissemination of mammary carcinoma. The subject at present is in a hazy condition. Invasion of the axillary glands is universally admitted to be an embolic process. As regards "regional" dissemination there are two views: 1. That invasion of the pectoral lymphatic plexus occurs by direct cancerous growth along the vessels. 2. That cancer cells are swept by the lymph stream through the vessels of the pectoral plexus and that metastases arise from their casual arrest at isolated points. As regards metastases in the internal viscera or at distant points in the parietes (*e. g.*, in the femur), there is only one definite theory of causation—that known as the embolic theory. The author is opposed to the view that the dissemination is an embolic phenomenon, and in this lecture reviews the evidence against that hypothesis.

3. **Mental Disorders of Decay.**—Savage, in the third of the Lettsomian lectures, first takes up the condition known as postponed idiocy, insanity of adolescence, or dementia præcox. There seems to be a definite class of individuals with a capacity to attain a certain stage; their nutritive powers are all right, but when with puberty, altruism, love, and allied emotional states come on, there is no power of resistance and these individuals break down. There seems to be a febrile condition that not infrequently ends in disturbance of the mind. The author then touches on disorders of malnutrition, toxic states, such as brain syphilis and general paralysis of the insane, and lastly true cases of senile dementia. Senility is not normal; it is not necessary that all persons living to be ninety should become senile. In many cases the senile dementia is but an exaggeration of the habits and ways of the man. The mental symptoms which are to be looked for as chiefly associated with mental decay in senility are loss of control, loss of faculty, and loss of flexibility. Loss of memory is most characteristic; this is also true of emotion, and there is a greater tendency to impulse. Sexual desire increases, due to defective control.

6. **Tuberculin.**—Shaw reviews the treatment of pulmonary tuberculosis by means of the tuberculin and antistreptococcus serum, and concludes that their use materially improves the results of treatment, and that the ordinary treatment by sanatorium methods should be supplemented with this specific one. Tuberculin treatment is of little use alone. "Old" tuberculin is practically a

glycerin extract of tubercle bacilli, and designed at first as a remedial agent, it has now become a most valuable diagnostic aid. The new tuberculin (*tuberculin K.*) is produced by triturating dried, highly virulent tubercle bacilli, mixing with water, centrifugating, and finally passing the resultant fluid through a Chamberland filter. It is not sterilized by heat, but glycerin is added for preservative purposes. The dose is expressed by weight of the dried substance contained in the fluid. It produces no local reaction at the seat of injection and appears to bring about immunity. Koch also produced other tuberculins (A and O), but these resemble "old" tuberculin and are but little used. Beranek's tuberculin, containing basi- and acidotoxines; Denys's, Hirschfelder's, and Hunter's—all resemble Koch's tuberculin. Klebs's tuberculoicin and antiphthisin come under the same head. Various antituberculous sera have been produced in the same way as antiphtheritic serum. Marmorek's is the latest to attract attention. Vaccination with attenuated or non-virulent tubercle bacilli has also been suggested. Antistreptococcal sera have been used in the hope of overcoming the serious secondary infections, and much is hoped for from the, so called polyvalent serum. In conclusion, the author gives the rules for the use of tuberculin in treatment, and some statistics based on the results obtained by various observers.

By MARSDEN.
3. The Relief of Respiratory Embarrassment in Malignant
Goitre,
By THOMSON.
4. The Limitations of Local Anæsthesia,
By MILES.
5. Doyen on the Ætiology and Treatment of Cancer,
By THOMSON.
6. Sir Thomas Browne,
By COUPLAND.

1. **Note on Decapsulation of the Kidney.**—Boyd and Beattie credit Harrison with suggesting incision of the kidney to relieve tension in nephritis in 1896. Edebohls subsequently suggested decapsulation on the ground that this operation is followed by the formation of new vascular connections between the kidney and its fatty capsule. The result of this increased blood supply and improved circulation is improvement and restoration to health of the diseased kidney. Experimental work which has been done with a view of testing the assertions of Edebohls shows that while a new capsule may be formed there is little anastomosis between the renal and circumrenal vessels. Ferrarini, however, found evidence that such a relation did exist. Upon the human subject a case is reported by Gibson in which a dense new capsule had vessels which anastomosed with the superficial vessels of the renal cortex. There was also prolongation of new fibrous tissue into the cortex accentuating the interstitial changes which were present before operation. Diminution of albumin, increase of urea, and increased diuresis have been observed after the operation. The diuresis may be due to relief of tension and im-

proved mechanical conditions in the circulation, or to the stimulation of the sympathetic centres which is caused by the operation. In either case the authors think incision of the capsule would be preferable. On pathological grounds the ultimate effects of decapsulation are thought to be of doubtful benefit.

2. **Late Rickets.**—Marsden summarizes his views by quoting Rassowitz, who states that a general withdrawal of nutrition, as well as the cutting off of the nutritive supply to a portion of the growing organism, can in a short time give rise to a well marked inflammatory state at the growing parts of the bone. Hence the causal connection between conditions which will produce rickets and the inflammatory changes referred to is made clear. A long continued defect in nutrition will ultimately produce the effect produced in a few days by general or local withdrawal of nutrition. Constant use of improper food, and faulty digestion and metabolism during the time of active growth, will result in abnormal condition of the newly formed tissues, appearance of general illness, insufficient increase in weight, and abnormal vulnerability of the tissues and organs. At the ends of the bones where energetic growth is taking place and where the faulty tissue is produced in greater extent than elsewhere, the vulnerability of tissue, and especially the imperfect structure of the walls of the young blood vessels, will be likely to lead to those inflammatory conditions which result in rickets.

4. **The Limitations of Local Anæsthesia.**—Miles thinks there is danger that local anæsthesia may be pushed beyond its natural and legitimate bounds, operations being frequently performed which would be carried out with greater efficiency and equal safety under the influence of a general anæsthetic. From operations which were recently reported are cited by him in which the shortest time was five hours and a quarter and the longest six hours and ten minutes. Although the time consumed in these operations was considerable, it is stated that aside from the fatigue the general condition of the patient was the same as before the operation. The experience was not painless in any of these cases, and the author believes that the unconscious condition, and the complete muscular relaxation under general anæsthesia would have enabled the surgeon to do better work than is possible under so called local anæsthesia. There is danger that in local anæsthesia discredit may arise by asking more from it than it can reasonably be expected to give.

5. **Doyen on the Ætiology and Treatment of Cancer.**—Thomson states that Doyen believes in the bacterial origin of tumors, and that vaccination against cancer is quite as feasible as vaccination against smallpox. Doyen made his first observations on the bacillus of cancer in 1885. In 1901 he called it *Micrococcus neoformans*. It is not stained with ordinary reagents, but is stained with a special fluid. It is easily cultivated, appearing after eighteen hours or more, the virulence of the culture being increased by passing it through rabbits, guinea pigs, white rats, or white mice,

and attenuated by adding quinine hydrochloride or exposing it to a high temperature. The micrococci are best seen in fresh nodules of secondary cancer, especially of the omentum. The more malignant the tumor the greater the number of cultures to be obtained from it. The cocci are best found in outlying lymphatic glands, and secondary growths; they have been found in the secretion of the mammary gland when cancer had not yet developed. Doyen believes the micrococcus causes the malignant tumors of the lower animals. Positive results from inoculation were obtained in five different species of animals. The toxins require two and a half or three years for their preparation. There is (1) an active toxine, and (2) an attenuated toxine. In preparing vaccines modified cultures two and a half or three years old are inoculated in tubes of bouillon and kept in the incubator ten or twelve months. They may be feeble or strong. The cultures are injected into the horse for ten months, after which the serum is available for treating cancer. The serum is injected into the buttock and is followed by a reaction like that from tuberculin in tuberculous subjects. Inoperable tumors after this treatment have become operable, and in some cases have ceased developing or have disappeared entirely. The knife should be used if it can go beyond the limit of the diseased tissue. Doyen considers five groups of cancer, clinically: 1. Superficial cancer of the skin without glandular infection, to be treated by incision, escharotics, x ray, or serum; 2. early cancer of mucous surfaces, and internal organs; which are limited, mobile, and without lymphatic involvement. These should be operated upon early, the serum being administered for one or two weeks before the operation; 3. progressive, extensive inoperable cancers. These should receive serum treatment, and after a few weeks may become operable. They should then be operated upon; 4. inoperable cancers of the skin *en cuirasse*. They should not be operated upon and the serum should be administered for several years; 5. cancers with glandular and visceral dissemination; with cachexia and debility. These are hopeless cases for serum or any other mode of treatment. Of 126 patients in Doyen's first series 79 received no benefit at all, the others were more or less relieved, 27 being considered cured. Of the second series operated upon since January, 1904, 20 seem to be cured, 7 are still under observation in good condition 24 are improved, 10 have not reported, 6 are too recent, and 49 are hopeless, 16 of them having already died. Out of a total of 242 patients 42 have been cured. These results have not been attained by any other mode of treatment. The ultimate aim is to vaccinate those who are in health and immunize them to cancer.

x. Regeneration of the Axones of Spinal Neurones in Man.—Shirres observes that doubt is widely expressed as to the possibility of such regeneration. Gowers considers it possible and notes a case in which there had been considerable destruction of the cord, with the corresponding symptoms, in which after many months there was return of sensation and motion. Years afterward when the patient died the cord was found to possess regenerated axones, very minute in size, where large nerve fibres are usually found. The absence of the neurolemma sheath is supposed to explain the failure of the spinal neurones to regenerate. If sudden pressure is exerted on the spinal cord for only a moment molecular changes occur in the axones of the spinal neurones, causing inhibition of function. If the pressure is prolonged, there will also be local anæmia and eventually necrosis. Nourishment and stimulation must be supplied, in such cases, to the cell bodies of the neurones, and electricity and massage must be used continuously to the tissues which are controlled by them. A case is described in which there was complete transverse division of the cord between the ninth and tenth dorsal vertebræ. There was no injury to the lower segment, and faradaic and galvanic stimulation of the muscles for six months, together with all other suitable attentions, kept the patient in good condition, but there was apparently permanent flaccid paralysis, sensory loss, and abolition of the reflexes. At the end of eleven months the wound was reopened and an interval of an inch and a half found between the segments. The muscles still responded slightly to mild faradaic stimulation of the anterior and posterior roots of the lower segment of the cord. A section of a dog's cord, freshly removed, three inches in length, was then laid beside the upper and lower segments of the patient's cord and the pia arachnoid of the one was united to that of the other by a few fine stitches. The operation was followed by recovery. Two months later there was sensation from the feet to the knees, also when a catheter was passed and when the bowels moved. A month later the subject died after a few days' illness. Autopsy revealed a large abscess of the right kidney. After the cord had been properly prepared a diffuent mass was found between the two severed ends. The upper segment showed ascending degeneration in the fields of Goll and Burdach in the direct cerebellar and in Gower's tracts. The lower segment showed degeneration in the crossed and pyramidal tracts. The dura with its adherent substances showed a mass of minute myelin sheaths of nerve fibres. Adherent to the dura and uniting above and below with the segments of the cord, showing that regeneration of the axones of the spinal neurones had taken place to a limited extent. The lower segment of the cord was in a fairly healthy condition, sections through the

cauda equina showing that 90 per cent. of its nerve fibres were normal.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, March 2, 1905.

The President, Dr. RICHARD C. NORRIS, in the chair.

The Indications for the Slow Induction of Premature Labor.—Dr. W. R. NICHOLSON, in this paper, mentioned the various rarer indications, such as insanity, nervous diseases, blood diseases, etc., but limited himself to the five most common indications, namely, contracted pelvis, placenta prævia, heart disease, tuberculosis, and toxæmia. While admitting that the rapid methods of delivery might very rarely be indicated in the treatment of some of these conditions, he expressed the belief that such indications were most unusual. Thus, in placenta prævia he acknowledged that there might be an indication found for the Cæsarean section if a primipara presented a condition of alarming hæmorrhage together with a rigid cervix, but in the vast majority of the cases of this abnormality no such indications existed, and the Cæsarean operation had no place.

In particular, should all rapid methods of cervical dilatation by means of the dilators of Bossi and Seigweaux be avoided unless the attendant was experienced in the use of such instruments. He was even more strongly opposed to the rapid methods of delivery in the presence of eclampsia. It was his opinion that Cæsarean section had absolutely no place here. He believed in the great value of the premature termination of pregnancy in the presence of certain grades of pelvic deformity, but was doubtful as to its utility in the presence of tuberculosis of the lung or cardiac disease, unless in the case of the latter the cause of the alarming symptoms was the mechanical pressure of the uterus.

The Indications for Accouchement Forcé.—Dr. GEORGE M. BOYD said that a difference of opinion existed among obstetricians in regard to the indications and methods of performing forced delivery, and assumed that this was due to the fact that as yet the problems were not completely solved. Accouchement forcé had at one time been accompanied with a large mortality, probably due to infection, and not to the fact that our forefathers were less skillful. There were two varieties of forced delivery: (a) The rapid method, which Zincke had stated represented the class of cases in which the condition of the mother, and sometimes that of the child, demanded a prompt and rapid termination of the pregnancy; and (b) the slow method, which represented those cases in which delivery might be effected slowly, because of the absence of immediate danger to the mother and the existence of a justifiable disregard of the life of the fœtus.

He described two steps in the operation: 1. Dilatation of the lower uterine segment and cer-

vix by stretching, tearing, or cutting. 2. Removal of the uterine contents manually or by resorting to instrumental interference.

Every method of operation had some objections. Manual dilatation had proved the most satisfactory in his hands, especially in treating eclampsia. The hand could best stretch the cervix. When the limitations of stretching were reached, it was better to make superficial or deep incisions.

In two cases of eclampsia recently seen in consultation, accouchement forcé had been successfully accomplished by this method. In both cases there was no evidence of the onset of labor after from four to six convulsions. The gestation was at the eighth month in one case and the seventh month in the other. The cervix was rigid in both cases, and the patient's general condition grave.

A Relatively Rapid Method for Terminating Pregnancy.—Dr. RICHARD C. NORRIS said that Nature's mechanism of dilatation of the cervix should be initiated by any method of artificial dilatation. The longitudinal fibres of the uterus exerted a direct pull upward of the lower uterine segment and, assisted by the downward push of the hydrostatic pressure of the bag of waters and later of the presenting part of the fœtus, the lower segment was dilated, and the internal os was opened and drawn upward, the cervix thus being attenuated and effaced. Mechanical stretching and thinning were not physiological dilatation, and that explained the lacerations so frequent after rapid and complete mechanical dilatation. During two years he had used a method combining the use of the bougie, partial mechanical dilatation to an extent not endangering the cervix (5 to 7 cm.), followed by the introduction of a very large bag of the Voorhees type (capacity, 600 c.c.), which, when incompletely distended with 480 c.c. of water, supplied an artificial bag of waters which, like the natural sac, was tense only during uterine contraction. Continuous or intermittent traction upon the bag might be employed when dilatation was inordinately slow. In thirty five cases of induced labor for the lesser degrees of pelvic contraction, terminated either spontaneously or by the forceps or version, the older method of a bougie followed by a bag had required an average of 27½ hours. In fifty-two cases managed by the same method, the indications being toxæmia, grave kidney, cardiac, or pulmonary disease, chorea, pernicious nausea, etc., the average duration, there being a larger number of spontaneous deliveries, had been thirty-four hours. In eighteen cases in which the use of the bag and bougie was preceded by partial instrumental dilatation, the average duration of labor was 8½ hours for cases terminated by the forceps or version, and 16½ hours for spontaneous deliveries, an average duration of 12½ hours for spontaneous deliveries and of 5½ hours for labors terminated by version or forceps.

Discussing eclampsia and placenta prævia in relation to accouchement forcé, he stated his conviction that in the former very rarely would a case present itself in which delivery in less than twelve hours was required. He discussed Bossi's

dilator and Dührssen's vaginal hysterectomy. He would reserve rapid delivery for a case showing no improvement after eliminative treatment was well under way, in which the toxæmia had not produced the gravest structural changes in the kidneys, but had overwhelmed the nerve centres. The character of the cervix more than its degree of dilatation and the state of the patient determined the choice between Bossi's instrument and Dührssen's hysterectomy. Bossi's instrument was dangerous when the cervix was tough, elongated, uneffaced, or scarred with dense cicatrices. Lacerations suddenly occurred in such cases without warning, and added shock and hæmorrhage to the gravity of the patient's condition.

Dührssen's vaginal hysterectomy, in the hands of a competent vaginal operator with efficient assistants, was less dangerous. The usefulness of either method for placenta prævia was even more restricted than for eclampsia. Central implantation in a primigravida, with a rigid cervix, profuse hæmorrhage, and a mature and living infant, furnished the only indication for accouchement forcé. He thought such a combination of conditions very rare. He had never encountered such a case. An infant often premature and usually apneic did not justify grave operation; a mother exsanguinated would not stand aggressive surgery. When the condition of both infant and mother warranted it, Dührssen's vaginal section in a well equipped hospital, with a skilled vaginal operator, was the latest and most promising contribution to the surgery of these rare cases.

The Methods of Inducing Labor.—Dr. BARTON COOKE HIRST said that since De Ribes advocated the use of his bag for inducing labor it had been a disputed point whether the old plan by bougies or the newer one by the inelastic bag in the lower uterine segment was preferable. He had given both methods an extensive trial, with the result that he found the bougie method the easier for the patient and operator and, if properly used, about as efficient as the bag.

(To be continued.)

Book Notices.

Normal Histology and Microscopical Anatomy. By JEREMIAH S. FERGUSON, M. Sc., M. D., Instructor in Normal Histology, Cornell University Medical College, New York city. With 462 Illustrations in the Text, many in Colors. New York and London: D. Appleton & Co., 1905. Pp. xix-738.

This somewhat massive volume has been written to furnish the student of medicine and the practitioner with a complete treatise on histology of the encyclopædic type with which we have been long familiar from the German laboratories. In the opinion of the reviewer it is perhaps the most satisfactory of such textbooks. To take up in detail all the special points which are of interest would lead too far afield, but we may say that the general get up of the volume is excellent, the type and paper are satisfactory, and the binding is sufficient, though the book does not open so well as a laboratory textbook should. The illustrations are in general exceedingly

good, if we except the colored plates, in which the color does not add much to the clearness from an educational point of view. The plates representing stained blood smears, while moderately satisfactory, would have been better had they been reproduced by lithographic procedures rather than by half tone. It still seems to be a difficult matter to obtain an accurate register in half tone color printing, at least in textbook work, and several of the cuts show the bad effects of these mechanical defects.

Of Dr. Ferguson's drawings of tissues, we can only say that they are most excellent and clear; in fact, we wish that he had redrawn some of the cuts taken from other authors. Half tone reproductions of photomicrographs have been introduced in considerable numbers, there being some one hundred and twenty-two in the book. Of these, many are strikingly good. Special attention may be drawn to those illustrating the arrangement of the tissues in the vessel walls, those showing structures in the lymphoid tissues, the sections of skin and nails, and, perhaps most remarkable of all, the photographs of the Graafian follicles of the ovary in various stages of development. Such photographs cannot but be of the greatest assistance, not only to the student, but to the practitioner of medicine who desires to freshen the memory of his laboratory studies in histology. The illustrations for the nervous system are also excellent, and the writer has done well to reproduce Marburg's plates showing the nerve tracts in the brain and cord.

The text of the volume is exceedingly clear and practical, those organs which are of interest to the worker in the field of surgery, gynecology, and neurology being dwelt upon in special detail. The ophthalmologist will find much to interest him in the description of the anatomy of the eye and the details of the innervation of the retina. The otologist will find a very complete description of the internal ear and its accessory structures, which may be of value, not only in a pathological sense, but as a guide in operative procedures. An excellent but concise chapter on technics follows the general text, and a very complete and accurate bibliography closes a volume which is a credit both to the writer and to the publishers. Only a moderate number of errors in the proof mar the text. These will be corrected, no doubt, in the next edition, which will surely be needed.

Gallstones and Their Surgical Treatment. By G. A. MOYNAHAN, M. S. (Lond.), F. R. C. S. Leeds. Fully Illustrated. Philadelphia: W. B. Saunders & Co., 1905. Pp. 386. (Price, \$4.)

The first chapter, on the anatomy of the gall bladder and ducts, is followed by others on the classification and formation of gallstones, on the general pathology of gallstone disease, and on its symptoms and signs. There are chapters that give an excellent description of perforation of the gall bladder and of intestinal obstruction due to gallstones. There is an admirable description of the details of preparation for operations upon patients suffering from gallstones and of the methods of operating upon the gall bladder and bile ducts. The author's descriptions are very clear and explicit, and the work is admirably illustrated.

Miscellany.

The Wisconsin State Board of Medical Examiners has licensed the following physicians to practise in that State:

Dr. C. H. Searle, of Palmyra; Dr. W. H. Johnson, of Mattoon; Dr. Henry W. Langheim, of Philippine Islands; Dr. S. E. Wright, of Chicago; Dr. L. E. Mason, of Chicago; Dr. James R. Robb, of Chicago; Dr. S. R. Perkins, of Waukesha; Dr. D. W. Wheelwright, of Belleville; Dr. Joseph Deane, Dr. A. Dalton, of Madison.

The Association of American Physicians.—The twentieth annual meeting of this association will be held in Washington, D. C., on May 16 and 17, 1905. Programme:

The President's Address, by Dr. E. L. Trudeau, of Saranac Lake; General Business; A Study of the Fear of Cats and the Power to Recognize Their Presence Unseen and Unheard, by Dr. S. Weir Mitchell, of Philadelphia; Intracapsular Lipoma, by Dr. R. H. Fitz, of Boston; Chylous and Chyliform Effusions Into the Serous Sacs, with a Case, by Dr. J. C. Wilson, of Philadelphia; Rhythmic Lateral Displacement of the Heart as a Sign of Unilateral Pleuritic Exudate, by Dr. Charles L. Greene, of St. Paul; Gonorrhoeal Septicemia and Endocarditis, by Dr. W. S. Thayer, of Baltimore; Fever in Chronic Endocarditis, by Dr. J. S. Thacher, of New York; Sphygmograms from Two Cases of Bradycardia, by Dr. George Dock, of Ann Arbor; Clinical Notes on Opium in Myocarditis, by Dr. J. H. Musser, of Philadelphia; Some Phases of the Neurotic Heart, by Dr. Beverley Robinson, of New York; The Frequency and Aetiology of Acute Non-Tuberculous Pneumonia in a General Hospital, by Dr. William T. Howard, Jr., of Cleveland; Report of a Case of Pneumococcus Sepsis, by Dr. J. S. Thacher, of New York; A Report of Six Cases of Perforation in Typhoid Fever in Children, by Dr. J. P. Crozer Griffith, of Philadelphia; Umbilical Hernia as a Little Recognized Source of Abdominal Pain, by Dr. D. D. Stewart, of Philadelphia; Stone in the Kidney and Certain Conditions Simulating It, by Dr. D. D. Stewart, of Philadelphia; A Study of Abdominal Tumors, by Dr. R. C. Cabot, of Boston; Hematemesis from Gastric Ulcer; Notes on 200 Cases, by Dr. W. G. Thompson, of New York; The Relations of Certain Stomach Disorders to Diabetes Mellitus, by Dr. John S. Sawyer, of Cleveland; Clinical Notes on the Use of Nux Vomica, Especially in Certain Forms of Hyperchlorhydria, by Dr. J. H. Musser, of Philadelphia; Election of Members; Considerations on Proteid Diet with Especial Reference to the Distribution of Amide-Nitrogen, Diamino-Nitrogen, and Monamino-Nitrogen Therein, by Dr. L. F. Barker and Dr. B. A. Cohoe, of Chicago; The Chloride Exchanges in Three Cases of Chronic Nephritis with Reference to the Dechloridation Treatment, by Dr. A. O. J. Kelly and Dr. Charles A. Fife, of Philadelphia; Chloride Retention in Nephritis, by Dr. Joseph L. Miller, of Chicago; On the Toxicity of Bile, by Dr. S. J. Meltzer and Dr. W. Salant, of New York; On the Nature and Origin of Cholemia and Uremia, by Dr. S. J. Meltzer, of New York; Xanthelasma and Chronic Icterus, by Dr. T. B. Fletcher, of Baltimore; A Report of a Case of Lymphatic Leucemia in a Child of Three Years of Age, by Dr. John Lovett and Dr. Harry C. Low, of Boston; Observations on Metabolism in a Case of Acute Leucemia and a Case of Purpura Hemorrhagica, by Dr. D. L. Edsall, of Philadelphia; The Influence of the X Ray on Metabolism in Leucemia, by Dr. J. H. Musser and Dr. D. L. Edsall, of Philadelphia; Chronic Acetanilid Poisoning, by Dr. D. D. Stewart, of Philadelphia; Report of a Case of Acromegaly, by Dr. Charles L. The Psychology of Dreams.—Jewell, in the *American Journal of Psychology*, for January, 1905, summarizes his study as follows:

1. Dreams may be prevented by suggestion, and probably disappear in proportion as the suggestion is complete.

2. Neither the season, day of the week, nor month has any noticeable effect on dreams, except for local setting, such as winter scenery being more common during the winter months.

3. There seems to be an age of dreams, about the time of puberty and dawning adolescence.

4. Motor activity during sleep is distinctively a childish characteristic, though it often persists into adolescence and sometimes well into adult life.

5. Dreams differ markedly with respect to age and locality, and probably with respect to nationality.

6. Children dream of the events which cause their great emotions very soon after their occurrence; after earlier adolescence such dreams do not occur for some time. During later adolescence and adult life, the more importance an event assumes to the individual, as a general rule, the greater the length of time between its occurrence and its appearance in dreams.

7. A number of returns suggest strongly that dreams of falling and flying differ only in apperception.

8. Many rational explanations of dreams usually classed as premonitory may be offered, leaving but a small residue unexplained.

9. While the judgment does not usually work logically during sleep, it may do so.

10. One may, while sound asleep, know that he is dreaming.

11. The emotions during dreaming are largely determined by the organic sensations at the time.

12. Since morbid fears are so easily engendered in small children by their dreams, care should be taken to prevent the suggestion of dreams which might have such an effect.

13. The confusion of dreams with real life is almost universal with children, and quite common among adolescents and adults.

14. The influence of dreams upon real life is vastly greater than is usually thought, as has been seen in many ways.

15. There may be subconsciously injected into one's dreams an element of truth which the dreamer does not recognize as subjective, hence they may take on a supernatural cast.

16. There is no mode of functioning of the mind in the waking state that may not take place during sleep.

The writer admits that these conclusions, to be positive, should be based upon a large number of returns from adults in middle life and in old age, and he has found it impossible to collect any considerable quantity of such returns thus far.

The Alcohol Question.—Thomas Dutton, M. D., in a recent number of the *Archives of the Röntgen Ray*, says that although the subject has

recently attracted some attention, still, in the interests of public health, it is imperative that the whole matter be carefully investigated and impartially discussed by medical men, particularly by those who can bring to its study the requisite knowledge, both scientific and practical, untainted by the blemishes of personal prejudice and faddish preconception.

Rabid teetotalism, even in writing for the medical press, has not always stopped short at the truth. With a puerile disregard for the mental capacity of the reader, the advocates of these self dubbed "temperance" principles have fondly imagined that dogmatic assertion, when backed by the cumulative force of assiduous reiteration, is tantamount to proof. By these means have they striven to bias judgment and convince all that alcohol produces a decline in the economic value of the organism by actual change in cell constitution—a statement which is quite untrue where the alcohol taken is pure and consumed only in moderate quantities.

I will venture to assert that fully 80 per cent. of the profession at large do both themselves partake of alcoholic stimulants in some form or the other and order it for their patients. Can it, then, with any show of reason, be maintained that this overwhelming majority have no knowledge of the true effects of alcohol? Can it for an instant be supposed that these members of a profession renowned throughout the world for its respect for the traditions and its scrupulous adhesion to the dictates of honor, are so morally degraded as to recommend a dangerous agent? The very thought is an insult to the dignified profession to which they belong.

As a counterblast to these concatenations of pseudoscientific balderdash, it may be observed that the American commission of experts, which has recently investigated the whole question, has unanimously come to the conclusion that "alcohol taken in moderate quantities is truly food." The *Lancet* has not hesitated in a leading article (January 21st) to state that alcohol must indeed be regarded as a food.

All admit that an excess of alcohol does harm; so likewise does an excess of meat, sugar, or even water. The danger here lies in the *abuse* and not in the proper *use* of the articles in question, and it is irrational to claim that their use must on this account be abandoned.

The best way for medical men to test the value of alcohol is by personal experiments on themselves. If the results of a thousand such experimental observations were forthcoming, we should have a collection of the valuable facts at our disposal, and upon these our deductions could be based. I once for three months drank daily a regular amount of wine and spirits. I found in two months that I had gouty pains, diminished appetite, and less inclination for work. I then left off everything for three months. I soon became very depressed; appetite and sleep failed, and still less inclination for work. I changed this the next three months to drinking wine, beer, and spirits whenever I felt inclined for some stronger drink than water. My appetite at once improved. I slept better and was ready for work at all times,

and the bowels acted regularly. I have since followed this plan, which I believe to be the best. I adopt the same plan with regard to meat. If I am obliged to remain indoors all day without any exercise, I eat only fish.

Experience leads me to believe that beer is the best drink for persons under the age of forty years, wine after forty, and that spirit should only be taken when required or ordered. I have great faith in sound, pure beer as a beverage for growing boys and girls, as well as for workmen; it seems to stimulate appetite, regulate the bowels, and promote healthy growth. If living in a wine country, I should order some variety of light wine instead. I have not found that children who are allowed beer take an excess of it when they attain to adult years; on the contrary, most of the drunkards I have been called upon to treat have been brought up on strict abstinence lines.

It is not unusual for writers who entirely forswear the use of alcohol to allege that all crime is produced through drink. I need only give one example to prove to the unbiased reader the untruthfulness of this statement. Our city fathers have, from time immemorial, drunk wine well, perhaps, but not always wisely; still, there is no record of their murdering or beating their wives on their return home, or of their committing any serious crime. The workingman, who perhaps only imbibes half the quantity of alcohol at a public house, may commit these outrages. To what, therefore, is the difference in conduct to be attributed? It is evidently not due to pure alcohol, but to a poisonous concoction, doctored with silent spirit, which is sold instead of the genuine article. Excess of pure drink merely causes a genial temperament, high spirits, an unsteady gait, and thick speech. The man or woman who overindulges is seldom vicious or quarrelsome. The spirits distilled from potatoes, maize, wood, etc., are responsible for the frenzy and dangerous symptoms that teetotalers associate with the use of alcohol. It should not be allowed to be sold under the most severe penalties. No doubt excess of any pure drink does undermine the constitution, and I must confess that many persons, both males and females, take too much; but this does not for a moment change my opinion as to the moderate use of alcohol.

I was much struck by a chance remark made by a very old (85 years) patient of mine. She said: "It is strange that when I was young all my friends partook of wine for dinner, and one seldom heard anything about indigestion, stomach complaints, or appendicitis; now my friends are all water drinkers, and they all suffer from these complaints. It is my opinion, doctor, that wine is an antiseptic and germ killer, hence the freedom from the complaints I have mentioned of those who take wine." I believe my patient is quite correct in her surmises, and that wine—more especially the red wines—have a germicidal action upon pathogenic microorganisms.

In concluding, allow me to appeal to the anti-alcohol writers to stay their hands and give their pens a rest. Let them, if they will, join forces with us in the endeavor to get a pure drink Bill passed through Parliament.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending April 22, 1905:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Florida—Jacksonville	Apr. 8-15	5	2
Florida—West Tampa	Apr. 8-15	1	0
Illinois—Chicago	Apr. 8-15	1	0
Kansas—Topeka	Apr. 1-8	2	2
Kansas—In 46 counties	Mar. 1-31	1,123	5
Kentucky—Louisville	Apr. 6-13	3	0
Louisiana—New Orleans	Apr. 1-15	39	0
Maine—Portland	Apr. 1-8	1	0
Michigan—Ann Arbor	Apr. 1-8	1	Imported
Michigan—Detroit	Apr. 8-15	1	0
Michigan—Grand Rapids	Apr. 8-15	2	0
Michigan—At 42 localities	Mar. 25-Apr. 1	Present.	1
Missouri—St. Louis	Apr. 8-15	24	1
New York—New York	Apr. 8-15	2	1
Ohio—Cincinnati	Apr. 7-14	1	0
South Carolina—Charleston	Apr. 8-15	2	0
South Carolina—Greenville	Apr. 1-8	3	0
Tennessee—Nashville	Apr. 8-15	1	0
Washington—Mason County	Apr. 8-15	1	0
Washington—Snobomish County	Mar. 1-31	2	0
Wisconsin—Milwaukee	Apr. 15	8	0
Smallpox—Insular.			
Philippine Islands—Manila	Feb. 18-25	2	1
Smallpox—Foreign.			
Argentina—Buenos Ayres	Jan. 1-31	28	5
Brazil—Rio de Janeiro	Mar. 19-26	4	5
Brazil—Bahia	Mar. 11-25	16	2
Great Britain—Birmingham	Mar. 18-25	2	1
Great Britain—Cardiff	Mar. 18-25	2	1

Peru—Lima	Mar. 12-19	2	2

Army Intelligences:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending April 22, 1905:

BILLINGSLEE, C. C., First Lieutenant and Assistant Surgeon. Granted two months' leave of absence.

CARTER, EDWARD C., Major and Surgeon. Granted two months' leave of absence, with permission to return to the United States from the Philippines, via the Suez Canal and Europe.

CRAIG, CHARLES F., First Lieutenant and Assistant Surgeon. Order relieving him from duty at the United States

Army General Hospital, Presidio of San Francisco, Cal., and assigning him to duty on the transport *Sherman* for duty in the Philippines Division, revoked.

EWING, CHARLES B., Major and Surgeon. Relieved from duty at the Columbus Barracks, Ohio, and ordered to Manila, P. I., for duty in the Philippines Division, on or about July 31, 1905.

HARRIS, H. S. T., Major and Surgeon. Relieved from duty at Fort Slocum, N. Y., and ordered to Manila, P. I., for duty in the Philippines Division.

KIERSTED, HENDRY S., First Lieutenant and Assistant Surgeon. Ordered to proceed from the Presidio of Monterey, Cal., with the Fourth Cavalry, to Sequoia National Park, Cal.

LA GARDE, LOUIS A., Major and Surgeon. Left Ancon, Canal Zone, on six weeks' leave of absence.

POWELL, JUNIUS L., Major and Surgeon. Relieved from duty at Fort Hamilton, N. Y., and ordered to Manila, P. I., for duty in the Philippines Division, about June 30, 1905.

RAYMOND, H. I., Major and Surgeon. Granted ten days' leave of absence.

REYNOLDS, F. P., Major and Surgeon. Ordered to proceed from the Presidio of San Francisco, Cal., to the Presidio of Monterey, Cal., with the Fourth Cavalry, for duty at the Yosemite National Park, Cal.

STILES, HENRY R., Captain and Assistant Surgeon. Left Washington Barracks, S. C., on ten days' leave of absence.

WILLCOX, CHARLES, Major and Surgeon. Ordered from Fort Totten, N. Y., to Fort Wadsworth, N. Y., for duty with the Fifty-sixth and Fifty-seventh Companies Coast Artillery to Artillery District of Baltimore, and then report for duty during Army and Navy maneuvers.

WINN, ROBERT N., Captain and Assistant Surgeon. Advanced to the rank of captain and assistant surgeon.

The following named assistant surgeons have been ordered to the Artillery District of the Chesapeake, Fort Monroe, Va., for duty during the Army and Navy maneuvers: First Lieutenants WALTER COX, GEORGE W. JEAN, PERCY L. JONES, WILLIAM W. RENO, C. P. ROBBINS, WILLIAM ROBERTS, R. M. THORNBURG, WILLARD F. TRUBY.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending April 22, 1905:

BERRYHILL, T. A., Surgeon. Detached from the *Oregon* and ordered home to await orders.

CLIFFORD, A. B., Assistant Surgeon. Detached from the Navy Yard, New York N. Y., and ordered to the Naval Hospital, Canacao, P. I., via the *Lawton*.

CHAPMAN, R. B., Assistant Surgeon. Detached from the Naval Hospital, Mare Island, Cal., and ordered to the Asiatic Station, via the *Lawton*.

DEAN, F. W. S., Surgeon. Detached from the Naval Station, Olongapo, P. I., and ordered to the *Frolic*.

DENNIS, J. B., Surgeon. Detached from the *Detroit* and ordered to Philadelphia, Pa., for special duty, and thence to Washington, D. C., to report to the Surgeon General.

GEIGER, A. J., Assistant Surgeon. Detached from the Naval Station, Port Royal, S. C., and ordered to the *Chesapeake*.

LEDBETTER, R. E., Passed Assistant Surgeon. Detached from the *Dixie* and ordered to the *Detroit*.

MCLEAN, N. T., Assistant Surgeon. Detached from the Naval Hospital, Boston, Mass., and ordered to the Naval Station, Guam, L. I., via the *Solace*.

MINK, O. J., Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the Asiatic Station, via the *Lawton*.

MUNSON, F. M., Assistant Surgeon. Detached from the Naval Station, Guam, L. I., and ordered home to await orders.

NASH, F. S., Surgeon. Ordered to the *Oregon*, via the *Lawton*.

NELSON, J. L., Assistant Surgeon. Detached from the Naval Station, Guam, L. I., and ordered home to await orders.

OMAN, C. M., Assistant Surgeon. Detached from the *Frolic* and ordered home.

OWENS, W. D., Assistant Surgeon. Detached from the Naval Hospital, Mare Island, Cal., and ordered to the Asiatic Station, via the *Lawton*.

PORTER, F. E., Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the *Dixie*, sailing from New York, N. Y., about April 26th.

SMITH, H. W., Assistant Surgeon. Detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the Naval Hospital, Canacao, P. I., via the *Lawton*.

STOOPS, R. E., Assistant Surgeon. Detached from the *Pensacola*, and ordered to the Asiatic Station, via the *Lawton*.

STRITE, C. E., Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the Asiatic Station, via the *Lawton*.

STURT, A., Passed Assistant Surgeon. Ordered to the Naval Station, Chelsea, Mass.

TOLFREE, H. M., Assistant Surgeon. Ordered to report to the Surgeon General for a course of instruction at the Naval Museum of Hygiene and Medical School, Washington, D. C.

WICKES, G. L., Assistant Surgeon. Detached from the *Lancaster*, and ordered to the Asiatic Station, via the *Solace*.

Births, Marriages, and Deaths.

Married.

OSBORNE—DOWNEY.—In New York, on Wednesday, February 22nd, Dr. Charles Cushman Osborne and Miss Julia Madeline Downey.

PIERCE—WAITE.—In Allston, Massachusetts, on Wednesday, April 12th, Dr. Charles W. Pierce and Miss Annie E. Waite.

Died.

ADAMS.—In Washington, D. C., on Sunday, April 16th, Dr. J. Lee Adams, in the sixty-fourth year of his age.

BASS.—In Cazenovia, N. Y., on Saturday, April 15th, Dr. Edgar C. Bass, in the seventy-fourth year of his age.

BEACH.—In Long Beach, N. Y., on Thursday, April 20th, Dr. William B. Beach, in the fifty-fifth year of his age.

BRICKER.—In Fostoria, Ohio, on Thursday, April 13th, Dr. J. W. Bricker, in the seventy-ninth year of his age.

CHENOWETH.—In St. Matthews, Kentucky, on Saturday, April 15th, Dr. Henry Chenoweth, in the eighty-first year of his age.

DWYER.—In Cincinnati, Ohio, on Friday, April 14th, Dr. Harriet Dwyer, in the eighty-sixth year of her age.

EATON.—In Brooklyn, N. Y., on Wednesday, April 12th, Dr. J. Albro Eaton.

GOWLING.—In Memphis, Tennessee, on Saturday, April 8th, Dr. Rachel Gowling, in the sixty-ninth year of her age.

HENDERSON.—In Cleveland, Ohio, on Friday, April 14th, Dr. F. A. Henderson.

HOFFMAN.—In Chicago, Illinois, on Thursday, April 13th, Dr. Adolph Hoffman, in the forty-fourth year of his age.

KENNEDY.—In Brookline, Massachusetts, on Thursday, April 13th, Dr. Alonzo Lewis Kennedy, in the sixty-first year of his age.

LUDWIG.—In St. Louis, Missouri, on Friday, April 14th, Dr. Charles V. F. Ludwig, in the seventy-first year of his age.

LUMMIS.—In Appleton, Wisconsin, on Thursday, April 13th, Dr. Henry Lummis, in the eightieth year of his age.

REANEY.—In Detroit, Michigan, on Monday, April 17th, Dr. Patrick H. Reaney.

STOKES.—In Morristown, New Jersey, on Wednesday, April 19th, Dr. N. Newlin Stokes, in the seventy-third year of his age.

POLITICOSOCIOLOGICAL ASPECTS OF TUBERCULOSIS PROBLEMS.

By JONATHAN WRIGHT, M. D.,

NEW YORK.

When there came that great leap forward in the development of the physical sciences during the first half of the last century, the results were soon thereafter seen in medicine in the perfection of the various mechanical means for the diagnosis and treatment of disease. This called forth and raised to eminence an order of talent which had but little adaptability and still less inclination for the cultivation of the arts and sciences and none at all for the humanities. The broader field of general medicine was neglected for the narrower domains of specialization. The mechanical side of medicine grew enormously. The era of the hod carrier in science was in full swing. The domain of ideas of intellectual processes was a neglected province; but this was not entirely or directly due to the intrusion of mechanics into science. To grasp the mere facts revealed by the microscope and the test tube, by the laryngoscope, and the thermometer required an intensity of application which precluded any broadness in the utilization of these facts for comparison and co-ordination. Twenty years ago all branches of medicine and the busy workers in them, the laryngologist, the neurologist, and the bacteriologist were characterized by a narrowness of conception and a feebleness of ratiocination which was a disgrace to the nobility of the human intellect, but the time has come and on every hand we see the indication of it when medicine is again to become a learned profession and a calling of enlightenment. While it is said that the recent Congress of Arts and Sciences, at St. Louis, was in some respects a lamentable failure, there may be seen running through the addresses of those men who have achieved prominence in even the most limited fields a conviction, as one of them expressed it, "that the most fruitful work in any science is to be done in the border line between it and

some other science." There has long been observed the expansion of biology and medicine until the line between them has been all but obliterated. With the broadening of our conceptions of ætiology in medicine we are coming into constantly closer contact with other phases of the enlightenment of modern civilization.

The enormous energy with which modern science is attacking the problems presented by cancer and consumption has brought this conviction home to us with more force than any other of the multitudinous activities which surround us in medicine. We have thus far obtained but little light as to the ætiological mysteries of the former, but as to tuberculosis we plainly perceive how largely its ætiology is bound up with sociological questions. Since the matter will concern us at another point let us instance a recent observation which has been dwelt on by several essayists. With the increase in the stringency of sanitary building laws in the large cities there has inevitably followed the higher price of living in them. Light and air have been commonly supposed to be about all that man has not appropriated from a beneficent Creator for the purpose of trade with his fellowman. Even these have not escaped. In urban life air and light are costly luxuries, and the inevitable tendency has been for the poor to seek them where they are cheapest. With the great increase in the means of transit this has become a possibility to the poor. Sanitary science but for this intervention of steam and electricity would be all but powerless to let in on the tubercle bacillus light and air, about the only efficient agents we have, either for the cure or the prevention of tuberculosis. The pressure on the poor is, still further even than by their own migration, relieved by the impulse of these in easier circumstances toward rural environments.¹ This is one of the world currents, remotely but directly ensuing on politicoeconomic changes, which will surely fortify the resisting power of

¹ This movement is apparent enough here in New York even to the casual observer, but those interested in the extent of it as revealed by statistics will find them in an interesting article in the *Nineteenth Century*, December, 1904, where the phenomenon as observed in London and England generally has been studied.

the average human cell, which even in this generation, but still more in succeeding generations, is to fight the noxious power of the tubercle bacillus.

The lack of differentiation between the effects upon the animal cell of different species of pathogenic bacteria, which characterized the earlier years of bacteriological science, resulted in placing in the same category the sprillum of cholera, and the densely hulled bacillus of Koch. We were led to look upon tuberculosis as analogous to the plague. Just at present the half alive intelligence of the public is being tickled by the glib and romantic phrase, The Great White Plague. This is an adumbration of a pernicious misconception once prevalent in more learned circles. It is an illustration of the awkwardness of educating the public. You no sooner have them educated up to one standpoint than you have to begin all over again. Lack of differentiation may be again observed in the influence which the signal triumph of serotherapy in diphtheria has exerted in attempting to find an antitoxine for tuberculosis. The treatment of tuberculosis has thus far yielded but paltry results. Such results as have been recorded we may to a large extent trace to improvement in the methods of the early diagnosis of the disease. In other words, we had forgotten in spite of innumerable warnings, and it was chiefly owing to the narrowness I have cited in my preamble that we did forget that ætiology is a complex problem, and that we have to consider the intrinsic factor fully as much as the extrinsic.

When we turn to preventive measures, as we shall see later, based upon such knowledge as the simple discovery of the tubercle bacillus afforded, they produced no effect upon statistics. The decrease in tuberculosis mortality did not begin in the early eighties. It began after the forties, when democracy had become triumphant. The prelude of the real fight with tuberculosis began when the desperate rabble of Paris, gaunt, hungry, with hundreds of years of misery as an inheritance, their body cells indeed a proper prey for the tubercle bacillus, "a million of tatterdemalions" stormed the Bastille and "girt the tall castle of Louis." The real fight with tuberculosis began not when Villemain proved its contagiousness in 1868, it began when his forbears died on the street barricades in 1848. Man wins his salvation only by shedding his very heart's blood; but unfortunately it is usually not by the heroics which swell so large in history. Here, however, the indications are clear enough. Some recent contributions, those, for instance, of Bul-

strode,² Newsholme,³ Ascher,⁴ contain collations of figures which afford ample evidence of the phenomena from which we may be permitted to draw the conclusions I have ventured to assert. In 1882 Robert Koch put the whole onus of tuberculosis on the bacillus, but historically it rests upon the despotism which prolongs the labor, takes the fat out of the food, and darkens the habitations of mankind. While it is prowling amidst the hovels of poverty it will occasionally knock at the door of a palace. In this country we are witnessing the ludicrous game known as robbing Peter to pay Paul, but as long as Paul only recovers a miserable pittance of that of which Peter has been despoiled, and that largely in the form of libraries and hospitals, the sport is not entirely devoid of themes for serious consideration.

The real fight against tuberculosis is not carried on by, nor do the base of its operations rest upon the activities of our health boards; it is carried on by that struggle of industrialism with militarism which is resulting in shorter hours for labor, better food for the workmen, and more of God's sunshine and fresh air for His children. It may be thought that I am stepping outside of my province as a physician in dwelling on these aspects of tuberculosis. They are not likely to be presented by the stipendiaries and the trustees of endowed libraries and laboratories, but they are none the less problems of tuberculosis, and how much more easy it would be to explain this part of the tuberculosis subject to the public than the mysteries of bacteriolysis, and those mystic symbols, the haptophore and the complement. They would understand at once. If we do not follow to their ultimate conclusions the results which our scientific toil has revealed to us, how can we plume ourselves on our growing catholicity of spirit? Shall we leave such things to the demagogues and harpies who more than once have played riot with such ideas? Better stir the porridge than allow it to cake over on the surface. We cannot be in the world without being of it, and the political evils of the day are as much a concern of medical science as is the search for an antitoxine.

So completely to banish the bacillus tuberculosis from the environment of man as to produce any appreciable effect on the sum total of deaths from tuberculous disease in the face of facts now available is a proposition to which common sense can no longer lend a courteous ear. So far at least

² *Lancet*, July 11, 1903.

³ *Lancet*, November 12, 1904.

⁴ *Brit. Med. Week.*, No. 44, 1904.

as concerns tuberculosis we know that strengthening the cells of the human body is the most efficient means of combating the scourge.

As I have said, laying aside here all purely biological themes, the statistics to support the trend of this article have been widely published. They have had their effect on current thought. Duckworth, Beavor, Bulstrode have in the last few years coordinated the results of statistical investigation, and in the address of more than one layman⁵ are conclusions which even the casual observer must find. Dr. Newsholm, in a very admirable article (*l. c.*), has dealt with this question of social evolution and the public health in England, and indeed it is probable that it will be fully discussed in all countries where thought is untrammelled by open tyranny or by covert repression. Newsholme points out that the general death rate in England and Wales has fallen from 22.5 per mille in 1854 to 16.02 per mille in 1902. As will later appear, this is not all to be credited to the diminution in the mortality from phthisis. This, however, has fallen much more steadily and markedly than the mortality from any other cause, and being a very large factor in the whole, about 1 to 7, it is very significant. When we turn to the study of the statistics from different countries so far as they go, they show that the decrease of mortality from phthisis has been proportional in each country to their advance in the equality of justice to all men, and of enlightenment in all classes. It has been proportional to the relief of the poor from unequal taxation. It has been proportional to the material prosperity of the whole people in each country. It has been more marked in the cities, perhaps not materially of late years because of the reason I have already cited; at any rate, it has been more marked in the cities than in the country, because better sanitation was not only more needed, but more practicable of attainment in the larger towns than in the country districts. This is particularly illustrated in Hamburg, where from 1840 to 1860 there were very great sanitary reforms—better drainage, better water. During that period, long before the modern conception of the communicability of phthisis arose, the mortality from it diminished. Dr. Reincke, from whom Dr. Bulstrode derives his statistics, informs him that no official steps had been taken up to 1896 to prevent the dissemination of the bacillus. Yet the second curve downward of the tuberculous mortality began in 1891, and hence Dr. Reincke attributes it to the improvement in general sanitation. Since 1896 the rate of decrease has been less.

⁵ See among others the paper by Professor Edwin Oakes Jordan, in *Science*, November 18, 1904.

So far, then, as the figures can show, there has been less improvement in the mortality statistics in the years since special measures against the bacillus have been in force, than in the corresponding preceding period, but of course we cannot assume that any immediate effect has been produced either for the better or worse in such a relatively short time. When we look at the statistics of France, where we know that material prosperity has not been so great as in triumphant Germany in the quarter century which followed the war between the two countries, we find a less favorable statistical summary, but owing to deplorable defects entire reliance cannot be placed in it. Nevertheless, it seems clear that France has lost more men by the indirect results of the Franco-Prussian war than by the fearful mortality of its battlefields. Notwithstanding that the improvement in the statistics has not been very marked in France, still some advance is observed. The Netherlands and Danish cities exhibit figures which, while not so striking as those of Hamburg, are of the same general character, and the same may be said of Vienna and Buda-Pesth, the capitals of the Austro-Hungarian Empire, and also of Switzerland.

A comparison of the figures of the health board of New York with those of Prussia and with other statistics is not encouraging for those who believe in the efficacy of specific sanitation for combating the bacillus tuberculosis. So far as figures can show, though of course the period of time is not sufficient, the rate of phthisis decrease inaugurated in the præbacillary days of the consumption theories has been checked rather than accelerated. The rate of decrease has been very moderate indeed in Italy where little improvement in economic conditions has been obtained in the last half century, while in Norway and Iceland there has been a marked increase.

It would not be profitable for me who am no statistician to attempt to point out the bearing of all the figures which have been collected. Neither dare I criticise what seem to me possible sources of grave error. Even with all the care skilled statisticians have devoted to the proper grouping of figures, there is none of them bold enough to deny considerable truth in Talleyrand's contemptuous reference to statistics as *le mensonge en chiffres* (the lie in figures). Nevertheless, we can see sufficient support in them for the attitude which modern science is taking toward the tuberculosis question.

Average modern man is a timid creature in the realm of ideas. His rich clientèle, he knows, will drop from him, donations will cease pouring in to

the coffers of his university, if he places his finger with requisite rudeness on the festering sore of the body politic,—which is indeed the true tuberculous ulcer. Most men are ashamed to lie to their fellows, but here and there is a man who is ashamed to lie to himself. Dr. Newsholme (*l. c.*) after asserting that “a large proportion of our population are still insufficiently fed and badly housed and suffer from conditions which must cause ill health and shorten life,” goes on to say what is not so apparent; “the public conscience no longer allows one set of men to support and enrich themselves by procuring the degradation and suffering of others.” The public conscience is a sleepy thing and needs vigorous perennial kicking, but if the eager health authorities want to educate their public, here is the chance. Just think for a moment of the health commissioner putting his finger on the tariff, or the trust laws, or the labor laws; *C'est à rire!*

Before us lies not only the correction of politico-social iniquities, but before us lies that entangling network of restrictions and petty regulations which the rules of the health and building boards and scores of others are weaving around man to protect him from the noxious influences of his environment. It is apparent that if modern civilization is to continue to advance we must give up many of our ideas of liberty. We must remember, if our altruism can be made to stretch so far, Holmes's suggestion, quoted by Bulstrode, that the proper season for bringing the influence of preventive medicine to bear on an individual is a hundred years before the child is born. The sires of future generations must make themselves the bondmen of rules which curb their desires and curtail their personal liberties.

If it really is the fate of our civilization that we are to drift into that state of intolerable supervision and minute regulation of daily life which distinguished that of the ancient Egyptians and Peruvians, it seems likely that the first step has been taken in the name of the public health. If a condition of practical slavery is the only one possible under which modern civilization can further advance, let us be sure we are selling ourselves at the highest market price. Let us not permit the infliction of regulations of-so called sanitation which are based on half baked theories, and the unwarranted deductions drawn from inept animal experimentation and inaccurate clinical observation, but let us see that blows are struck in the body politic in behalf of the animal cell, which has to fight the ubiquitous microphytes of disease which it is impossible to banish from contact.

44 WEST FORTY-NINTH STREET.

DIETETIC EXERCISES IN INFANT FEEDING.

By E. KIRKLAND SHELMERDINE, M. D.,

PHILADELPHIA.

Infants who require artificial feeding can be divided into three groups: 1. Easy cases. 2. Difficult cases. 3. Very difficult cases.

EASY CASES.

Some children have digestive systems capable of assimilating almost any combination of milk; these children apparently thrive on milk and water mixtures, provided that the food is not too concentrated in the beginning. It is true, however, that even in these cases a too great liberty in the question of diet will often result disastrously; but if ordinary precautions are observed, they pass through infancy without any gross disturbances of digestion. The tranquillity of their progress is not as serene as it would have been had they been scientifically fed; but the minor attacks of colic and digestive disturbances have only been of sufficient moment to inflict loss of patience and sleep on the part of the caretakers, without seriously affecting the general health of the infants themselves. The peevishness and disagreeableness in general of an infant are not always attributed, by either the mother or the attending physician, to the fact that the harmonious normal chemical changes of the food in its passage from the bottle to the diaper, is perverted by errors of metabolism, resulting from the improper proportions of the fundamental constituents of milk. It can be put down as a maxim that well fed babies have universally a bright sunny disposition; by well fed I do not mean overfed, but scientifically fed in respect to the quantitative and qualitative chemical proportions of the food. When an infant is properly fed its resistance to disease is greater, owing to its more perfect constitution than if its tissues were strained, as it were, from errors of diet. Admitting the fact that some infants apparently get along very well on most “any old diet,” yet it is true, nevertheless, that these same infants, if properly cared for in respect to time and composition of food, would be hardier and more amiable.

It is as easy and sometimes easier for a physician to start an infant in the right direction as it enters upon its bottle career, than it is to send it along the wrong and uncertain pathway of unknown milk combinations. With modified milk mixtures, it is only a question of finding out which of the milk constituents is at fault and remedying the errors by increasing or decreasing the percentages, according to the indications. Too much

emphasis cannot be laid upon the desirability of feeding all babies, who require to be artificially fed, with modified milk mixtures. To-day, this is possible by the home modification of milk;¹ the cost is only a trifle, if any, more than that of ordinary milk. Many physicians when modified milk is mentioned at once think of laboratory feeding and what is, to many families, the prohibitive cost of the same.

While it is impossible to make a table which will cover all cases, yet for the average healthy child who for any reason is deprived of mother's milk, the following series will answer for the majority:

TABLE NO. I.

	Percentage			
	Fat	Sugar.	Proteids.	Alkalinity.
First week.....	2.0	5.0	0.75	5.0
Second week.....	2.5	6.0	1.0	5.0
Third week.....	3.0	6.0	1.0	5.0
Four to six weeks.....	3.5	6.5	1.0	5.0
Six to eight weeks.....	3.5	6.5	1.5	5.0
Two to four months.....	4.0	7.0	1.5	5.0
Four to eight months.....	4.0	7.0	2.0	5.0
Eight to nine months.....	4.0	7.0	2.5	5.0
Nine to ten months.....	4.0	7.0	3.0	5.0
Ten to twelve months.....	4.0	5.0	3.5	5.0

At the beginning of the second year plain milk is given.

The casein of cow's milk is much more difficult of digestion than human milk; the organs of the child have to be educated to the point where they can digest whole cow's milk. During the course of the first year, this tolerance is brought about by gradually increasing the proteids from a low to a high percentage. The principal mistake is made by giving a too high percentage of proteids at the start. When the mother is unable to nurse the child from the beginning, the foregoing table will give extremely satisfactory results; in fact, these cases are by far the most satisfactory to treat; if properly started, there is very little difficulty; the hard cases are those in which have been given all kinds of mixtures and foods until the digestive system has been almost ruined.

DIFFICULT CASES.

No hard and fast rule can be given for infant feeding any more than a definite course of treatment can be given for each disease which man is heir to; if it was possible to arrange the feeding of infants and the treatment of the sick by rule of thumb, physicians would be relegated to the ash heap, and it would be possible for every household to have an "Every Man His Own Physician" lying handy on the centre table. In the successful administration of modified milks as well as the prescribing of medicine to the sick, the success of the physician depends upon his skillful diagnosis and the proper appreciation of

the idiosyncrasies of the individual patient. In treating a child whose digestive system has been maltreated, it is essential that the attending physician should have the all seeing eye. The history of the case is not sufficient; the general appearance of the child, its size and weight, the muscular tone, the action of the skin: all these important diagnostic points should be carefully observed. Most important of all is the character of the vomitus and feces; it is from these that very important facts are obtained. By close observation of the ejections from both ends of the gastrointestinal canal, we are able to determine if any of the constituents of the milk are at fault.

In the limited scope of this paper it is impossible to go into the minute details of modified milk feeding, yet a general outline of the more important points to be observed in varying milk proportions will, I hope, be of practical use to the busy practitioner who has in the past not used modified milk feeding, owing to its supposed complexity.

Too Much.	FAT.	Too Little.
Vomiting or the regurgitation of sour masses of food.		Constipation.
Diarrhea, loose movements, usually of a yellow or yellowish green color and sour odor; sometimes white, smooth and formed with a peculiarly offensive odor; reaction acid.		Malnutrition.
Free fat may be present in the stools or appear as small yellowish white masses resembling casein, but distinguished by their solubility in alcohol and ether.		Cold extremities, due to non-generation of sufficient body heat.
PROTEIDS.		
Too Much.		Too Little
Colic, either gastric or intestinal.		Malnutrition.
Constipation more often than diarrhea.		Low muscular tone.
Curds in the stools; reaction, alkaline.		Deficiency in height and weight.
Vomiting is often present.		
Stools, pale yellow or white, frequently formed, with an odor of cheese; at other times foul; large masses of casein. Insoluble in alcohol and ether.		
SUGAR.		
Too Much.		Too Little.
Flatulence, gastric and intestinal.		Excessive leanness.
Colic and diarrhea alternating with constipation.		
Stools offensive, thin and sour; frothy from gases liberated by decomposition.		
Vomiting and regurgitation of food sometimes present.		

NOTE.—Too much or too little of more than one of the ingredients of milk may modify the above symptoms. In their order of frequency proteids are the main source of trouble; next comes the fat, and, rarely, the sugar. Excess of proteids is indicated by masses of casein, excess of fat by masses of fat in the stools.

A child who is being improperly fed may or may not have signs of malnutrition. Weight and length are below normal; there is lack of muscular tone; the child sleeps badly, is restless, peevish, and irritable; the digestive and assimilative organs have impaired functions, causing vomiting, diarrhea, or constipation; anæmia is generally present. These children are generally backward in

¹ See Long and Short Methods of Calculating Modified Milks, *New York Medical Journal and Philadelphia Medical Journal*, November 19, 1904.

teething, they sit up later in life than the average baby, it is an effort for them to hold their heads up for any length of time. Emaciation and feebleness are pronounced.

In the majority of cases, where the physician is not sure of the purity of his milk supply, it is well to have the food Pasteurized. In some cases children become scorbutic from Pasteurized milk. These are very few, however, and where signs of beginning scurvy are present, raw milk should be substituted. In using modified milk, the prescription depends upon which of the constituents is at fault. If the child is suffering from an attack of any of the various gastric or intestinal disorders, it depends upon the severity of the symptoms whether a modified milk should be started at once or whether the child should be taken off a milk diet altogether for a time and put on a grain water until the severity of the symptoms subsides. Where there is also a pronounced infection, probably from impure milk or undigested masses in the alimentary canal, it is wise to give the whole tract a thorough cleaning out with calomel. After the subsidence of the graver symptoms, it is well to put the child on milk in which both the fat and proteids are low, then increase proportions as the exigencies of the case demand. It is a good rule in infants up to six months of age, who have been previously ill fed, to start them on 2 per cent. fat; 0.75 per cent. proteids; 5 per cent. sugar; and then gradually or quickly, according to circumstances, run the proportions up to the point where no symptoms are present as a result of a too high percentage of any of the ingredients. In children who have been poorly fed, every case is a law unto itself and the success of the feeding depends upon careful investigation of conditions which point to a too high percentage of one or more of the milk constituents. Holt² gives the following general rule: "If not gaining in weight and without special signs of indigestion, increase the proportions of all the ingredients; if habitual colic, diminish the proteids; for frequent vomiting soon after feeding reduce the quantity; for regurgitation of sour masses of food, reduce the fat, and sometimes also the sugar; for obstinate constipation, increase both fat and proteids."

Improper feeding is the main ætiological factor in malnutrition, marasmus, rickets, scurvy, and the various gastrointestinal disturbances.

DIAGNOSTIC POINTS.

Fæces.—In breast fed babies, the fæces are smooth, yellow, and soft, acid in reaction, and have no disagreeable odor. In infants who are

taking properly modified milk, the fæces are practically the same, generally more solid and firmer; reaction neutral or alkaline. With an excess of proteids, the alkalinity is increased, owing to the presence of undigested casein. When the proteids are excessive they can be detected in the fæces, often in large amounts, the stools becoming pale yellow or even white in color; the odor is often similar to that of cheese, at other times foul from the decomposition of the casein. Excess of fat manifests itself by diarrhoea and fatty masses in the stools. Too much sugar in the food is shown by diarrhoea and thin, sour, irritating stools.

Gastric disturbances are indicated by vomiting, gastric colic, regurgitation of food or water, belching of gas, and a coated tongue.

Intestinal disturbances are indicated by intestinal colic, flatulence, distention of the abdomen, diarrhoea or constipation, curds or mucus in the stools.

Diarrhoea.—In their order of frequency, may be caused by: 1. Too much fat. 2. Too much sugar. 3. Too much or too little proteid.

Constipation.—1. Too low a percentage of both fat and proteid. 2. Too much proteid and too little fat. 3. Too much proteid.

Vomiting.—1. Too large a quantity at one feeding. 2. Too much fat. 3. Too much proteid. 4. Too much sugar.

VERY DIFFICULT CASES.

From previous improper artificial feeding, or poor breast milk, or a poorly developed digestive system, some infants' digestive powers are exceedingly feeble. Poor digestion or chronic indigestion is generally due to previous improper feeding; in the majority of cases, it is not the result of inherited defects. There are infants who are unable to digest even very low milk percentages. Such infants are generally those whose digestive systems have deteriorated from the use of improper food which the body has been trying to assimilate; the digestive organs have almost given up the fight, and it is only a question of time when the infants would succumb to the inevitable. It is a question of starvation in the midst of plenty, more than sufficient food being supplied for the infant's needs, but owing to the superabundance of food constituents in the milk, the small amount of secreted digestive juices is not sufficient to perform the necessary chemical changes in the food mass. In other words, if the milk percentages were proper, the amount of enzymes present would be sufficient to bring about the splitting up of the food molecules into combinations capable of absorption and assimilation.

These cases are the ones which try out the skill of the physician, and it is only by close attention to minute details that he achieves success. The history of the case is that the child has been fed on all sorts of milk mixtures and patent foods, or that the child has been given table food. It is not uncommon to see in the medical journals and advertisements of patent baby foods, that a child had been fed on modified milk with negative results; such a statement contains just as much worth as one to the effect that a physician had given medicine without good results; neither statement is proof positive of the

are reached. By this procedure some children who are apparently hopeless will thrive and in a few months be able to digest a percentage of proteids which would have been fatal without this training.

Whey is prepared by adding a half of a junket tablet to a pint of milk. This is allowed to stand for a short time until coagulation takes place; the curd is then broken up by stirring and the liquid strained through a muslin cloth without any pressure. It is better to have a cloth so large that the ends can be tied together and to hang it up over an open jar.

TABLE NO. II.—WHEY MIXTURES.

	16 per cent.		Boiled		Milk sugar,	Fat.	Sugar	Proteids.			
	Whey.	cream.	water.	Time	Heaping	Per ct.	Per cent.	Milk Lactalbumen	Whey Lactoprotein	Alka-	
	Ounces.	Ounces.	Ounces.	Ounces.	teaspoons.			Per cent.	Per cent.	linity.	Per cent.
Whey made from whole milk..	8	..	7	1	2 $\frac{1}{4}$	= 0.5	4.5	..	0.50	6.25	
	[4	1	10	1	3 $\frac{3}{4}$	= 1.0	4.5	0.25	0.25	6.25	
Whey made from skimmed milk.	8	1	6	1	2 $\frac{1}{4}$	= 1.0	5.0	0.25	0.50	6.25	
	8	1 $\frac{1}{2}$	5 $\frac{1}{4}$	1	3	= 1.5	5.5	0.37	0.50	6.25	
	(8	2	5	1	3 $\frac{1}{2}$	= 2.0	6.0	0.50	0.50	6.25	
Skimmed milk.....	1	2	12	1	4 $\frac{1}{2}$	= 2.0	6.0	0.75	..	6.25	

fact that proper therapeutic measures had been adopted. So in some of the histories of badly fed babies, there is the statement that modified milk mixtures have been tried; this is to be disregarded and proof of the actual inability of the child to take modified milk is to be personally investigated. The sanitary conditions of the milk supply as well as the conditions surrounding the journey of the milk from the cow to the baby's stomach should be thoroughly investigated. Rigid cleanliness both on the part of the child's caretaker in her preparation of the food and in the milk supply itself, are necessary adjuncts to the proper feeding of infants. There is no better procedure in all cases than to begin treatment by cleaning out the child's digestive tract; calomel in divided doses followed by castor oil is a good routine remedy.

In some few cases it will be found that even a low percentage of proteids is not well borne. When such is found to be a fact, one of two procedures is to be tried; either to put the child on a grain water for a time until the digestive organs have had a rest and then begin with a low proteid percentage, or to start it on whey mixtures. The casein of cow's milk is much harder to digest than is the casein of mother's milk; it is mainly on this account that some children suffer from malnutrition. The lactalbumin is more readily digested and the digestive organs can be gradually trained to digest increasing amounts of proteids, by starting on a whey mixture in which casein is absent, and then gradually adding milk proteids until the regular modified milk mixtures

[The above table is calculated on the basis that the average composition of whey, according to Adriaenc, is as follows:

	Whole milk.	Skimmed milk.
	Per cent.	Per cent.
Proteids	0.94	1.17
Fat	0.96	0.04
Sugar	5.49	5.36

In the milk proteid column are the proteids derived from the added cream, which contains casein in proportion to lactalbumen as 6 is to 1; therefore one-sixth of the percentage in this column is really lactalbumen. Whey proteids are composed chiefly of lactalbumen, with a smaller proportion of lactoprotein.]

Where whey mixtures are necessary, the first combination can be given for a short time; then the second, the percentage of proteids being so low that no disturbance is to be feared from this mixture. Every few days the percentages can be increased until the whey is discontinued and the child put on regular modified milk. By this graduated exercise of the digestive functions, as it were, the alimentary tract is trained to digest increasing percentages until the child is finally receiving an adequate amount of nourishment.

ILLUSTRATIVE CASE.

John D., aged 6 months; weighed eight pounds at birth, breast fed for three weeks when mother's milk failed. Put on milk and water mixture, milk one part to three of water; proprietary foods tried; proportions of milk and water frequently changed. Bowels were never proper; curds and green masses in the stools; attacks of vomiting, sometimes food, sometimes sour water; frequent attacks of colic. Had been heavier than he was then. For the past week had been fed one part of milk to two parts of water.

Inspection.—Child's face thin and drawn; body emaciated, abdomen enlarged; weight eleven pounds, length twenty-four inches; stools con-

tained large masses of undigested casein and some fat, very offensive; bowels moved ten to twelve times a day.

The milk supply was from a dealer who had a wagon route, and in all probability was purchased in the open market.

June 8th.—The child was given a tenth of a grain of calomel every half hour until twelve doses were taken; this was followed by a tablespoonful of castor oil. The mother was instructed how to make barley water, and six ounces were ordered to be given every two hours; twenty drops of whiskey were given four times a day. This treatment was continued for two days, when the diarrhoea practically ceased.

June 10th.—The child was put on fat, 2 per cent.; proteids, 0.75 per cent.; sugar, 5 per cent.; which was continued for three days, when the diarrhoea returned with casein in the stools.

June 13th.—Calomel and castor oil were given and the child put on the No. 1 whey mixture, six ounces every two hours. At the end of three days the diarrhoea had subsided.

June 16th.—No. 2 whey mixture was given.

June 18th.—No. 4 whey mixture was given.

June 20th.—No. 5 whey mixture was given.

June 22nd.—No. 6 whey mixture was given.

This was continued for ten days without any return of bad symptoms. At intervals of ten days the percentages were increased according to table No. 1, until the child at 8 months was receiving a percentage which would be applicable to a child 6 weeks old.

August 1st.—During this time the child had increased twenty ounces in weight and an inch in length; his height was about the average, but the weight was still below normal. The muscles were beginning to have more firmness; the eyes were brighter, and the general appearance of the child had improved.

August 15th.—The food was further increased to fat, 3.5 per cent.; sugar, 6.5 per cent.; proteids, 1.5 per cent.

September 1st.—Fat, 4 per cent.; sugar, 7 per cent.; proteids, 2 per cent., were ordered. On this combination the child was kept for three months, as several attempts to increase the proportions resulted in trouble; this combination appeared to be the limit of tolerance.

January 1st.—Fat, 4 per cent.; sugar, 7 per cent.; proteid 2.5 per cent., were ordered and the proportions gradually increased until at 18 months of age the child was able to digest whole milk.

At 8 months of age he suddenly developed grass green stools; a careful investigation of the case brought out the fact that the mother was using unboiled water. She had been told to boil all the water used, and then shown how to Pasteurize the milk after making the mixtures. She thought that the home Pasteurization sterilized the milk. Coincident with this attack of intestinal infection, there was a break in the reservoir supplying this part of Philadelphia and the water was especially foul. By carefully cleaning out the intestinal tract and sterilizing the water, the attack subsided in the course of a few days.

This case was one of the rare ones in which the child was unable to digest high percentages of proteids until long after the age when the average child was taking whole milk. He thrived on low percentages, however, and at 2 years of age was of average length and only slightly under weight. To-day he is able to eat a diet which is appropriate to his age, and is physically a strong, healthy boy, a living example of what graduated exercise will do for the digestive organs. As we can take a weak, delicate boy and by physical culture develop him into a robust being, so can an infant with weakened digestive organs be trained into digestive competence.

6135 GERMANTOWN AVENUE.

INFLAMMATION OF THE GLANDS OF BARTHOLIN.

By CHARLES C. MILLER, M. D.,

CHICAGO.

(Concluded from page 848.)

THE EXTIRPATION OF THE ACUTELY INFLAMED GLAND, WHEN COMPLICATED BY THE STRICTURE OF THE DUCT AND THE RETENTION OF PUS AND SECRETIONS.

We now come to the most certain and radical method of treating that condition, which up to the present day has merely been looked upon as an acute inflammation of the gland.

Where this process is marked by any decided symptoms, this operation will require a general anæsthetic, or an extensive infiltration anæsthesia. I have never tried this latter plan, and cannot recommend it from experience, but when one comes to a consideration of several of the inconveniences which are likely to come from local anæsthesia, I think it will hardly prove desirable in these cases where considerable inflammation exists.

The patient should be carefully prepared by being scrubbed, shaved, and douched. This latter should be thorough in any case, and where the woman is suffering from a rather profuse purulent discharge, as we sometimes see, the vagina should be scrubbed out with green soap and a brush.

The patient is to be given a general anæsthetic and placed in the lithotomy position. The buttocks should extend well over the edge of the table so as to give good access to the parts.

Where there is a large accumulation of pus it is quite impossible to dissect out the tumor and cyst without rupturing the latter, but if the operator is anxious to do this or rather to prevent an infection of his wound so that it may be imme-

diately sutured without drainage, the pus and gland secretions may be carefully aspirated, and the cavity of the abscess filled with melted paraffin as was suggested by Pozzi some years ago in the treatment of cysts of the gland. Then the entire gland, the mass of paraffin within it, and the dilated duct may be removed. Should the paraffin be exposed during the operation, the wound will not at once be inundated with pus as would be the case were the abscess opened. In this technics, where the paraffin is used, should the solid mass be exposed at any time during the operation, a stitch should be taken to close the little rent into the infected sac. Where care is used to see that the sac is empty before the paraffin is injected, the paraffin may be repeatedly exposed and infection prevented by suture and, at the conclusion of the operation, the parts can be closed by immediate suture.

If the paraffin is not to be used and there is a large cyst, an effort may be made to remove tumor and cyst without rupture of the latter, but as a rule the cyst will be ruptured early in the operation. The pus which escapes should be carefully removed from the field of operation.

The skin incision is much preferable to the one made on the inner surface of the labium majus, the reasons for which I have previously mentioned.

The gland usually comes into view as an irregular purplish body, and varies greatly in size; one the size of a hen's egg is not unusual after the pus has escaped.

The dissection is to be made over the anterior surface of the gland at first, and in so doing it is well to dissect free that portion nearest the rectum before attacking the portion near the bulb of the vagina which lies anteriorly. A free oozing commences as soon as the dissection has been well started, and in some cases this portion of the operation may be continued under continuous irrigation to advantage. Any spurting vessels should be caught with hæmostats, and if these are in the way the vessels should be tied or twisted and the hæmostats removed.

As the dissection is continued deeper around the sides of the gland, the bleeding becomes quite inconvenient. The irrigation is useful, so long as the dissection is superficial, but when we get well down to the posterior portion of a large gland it is of little service.

While conducting the dissection, work is much facilitated by traction upon the gland if the cyst has ruptured, but it will be necessary to have broad flat forceps for grasping the gland if we wish to make any degree of traction, as the gland

structure is usually very friable when the organ is badly diseased.

In carrying the dissection down upon the inner side of the gland care should be taken to prevent rupturing the intervening sæptum between the wound and the vagina. Some recommend that all portions of the gland be removed, but by so doing only a sæptum of extreme thinness is left on the vaginal side. I prefer in some instances at least not to do so. If only a sæptum of mucous membrane is left between the wound and the vagina, and free suppuration develops during the subsequent course of the case, I have in several instances seen the sæptum slough, so that a communication develops between the wound and the vagina, and this organ is exposed to the danger of reinfection.

In all instances where the gland has projected well toward the vagina so that only a very thin sæptum would be left if all the gland was removed, I prefer to carry my incision through the gland structure to this inner side, leaving a small portion of the gland to reinforce the inner wall.

In one of my cases following sloughing of the sæptum between the wound and the vagina, where the incision was made at the juncture of the two labia, a fistula developed which was cured only at a second operation.

The vagina should be avoided with particular care in those cases where there is a free purulent flow from this organ, as in such an instance communication will mean certain infection of the cavity of the wound, a condition which can be avoided in not a few cases even where a cyst filled with pus is ruptured during the operation.

The most important feature of the radical operation for the extirpation of the enlarged and inflamed gland is the control of hæmorrhage. It has been the experience of more than one surgeon to find that he cannot simply pack the cavity which is left after the extirpation of this gland, and by this means effectually guard against hæmorrhage. Large amounts of blood have been lost after this operation, where the operator has not completely controlled the bleeding and has trusted to a gauze pack of the wound.

We can to some extent avoid free bleeding by keeping very close to the gland anteriorly toward the pubes and thus avoid the vascular erectile bulb of the vagina, and in making the dissection of the gland behind after it has been separated on all sides, blunt dissection has been recommended to avoid wounding some of the vessels which are situated in this region.

It has been my experience not to have trouble with any large single vessels, but to find after the

gland was removed that there was a free bleeding which could not be localized to one or even to a few points. Hot irrigations during and after the operation and hot compresses packed into the wound do not serve to control this bleeding.

The most efficient means, as I have described before, is by the use of the mattress suture of catgut, which is carried under the bleeding surfaces. I would here repeat that it is not necessary to strangulate the tissues by tying these sutures as one would a ligature.

In order to make it possible to pass the mattress sutures in the depth of the wound, and some of the wounds left after the extirpation of a large gland are deep, it is well to have at hand some very short full curved needles.

Sometimes a wound is deep and conical after the extirpation of the gland and the operator does not care to close it even in part by the mattress sutures, owing to the infected inflamed condition of the tissues and there is a persistent free bleeding; this bleeding can be controlled by packing, but we must exercise one or two precautions to render the packing safe. The wound may be packed with gauze and then the superficial parts drawn over the gauze and sutured, leaving only a small opening posteriorly for the exit of a small rubber drainage tube. At the end of twenty-four hours a greater part of the stitches must be cut and the gauze removed and replaced by clean gauze.

Another method of packing which is safe and in which the superficial parts are not closed over the gauze, is the method of packing the vagina solidly with lint or gauze and then packing the cavity firmly. A compress must then be carefully applied to the external parts to hold the gauze effectively in the wound. The vaginal packing need not be replaced when the gauze is changed at the end of twenty-four hours unless a free bleeding recommences, when the vagina and cavity must be again packed to control the bleeding.

In any case after this operation, unless the bleeding has been perfectly controlled during the operation, a nurse should be instructed to inspect the parts without disturbing the dressings at least every half hour.

NEGLECTED CASES OF BARTHOLINITIS COMPLICATED BY FISTULA.

We sometimes see a patient who has allowed an abscess to form and rupture into the vagina or burrow posteriorly into the rectum. The formation of vaginal fistulæ is much more common than those into the rectum.

Where the fistulæ have formed extending into the vagina or even open on the inner surface of the labium minus, the incision to the gland may be through this area, but for my own part I prefer in these cases to make a skin incision and then if possible to excise the fistulous opening into the vagina and close this point so formed by chromicized gut or other sutures. Drainage will then occur externally, and the least amount of scar tissue will be formed at the former site of the fistula. This plan has the advantage that reinfection of the wound is less likely to occur, and the danger of an ascending infection being lighted up where it has subsided is overcome.

Cases where there is a rectal fistula as the result of the infection of Bartholin's glands are cases which have been neglected for considerable time. In some there will be no communication with the vagina, and these cases are to be operated upon as are all rectal fistulæ.

I do not wish by entering into a lengthy consideration of the operative treatment of diseases of the gland of Bartholin for my readers to lose sight of the points which I attempted to bring out in the earlier part of this article regarding chronic inflammation or infection of the duct and gland without stricture, and the suggestions as to diagnosis and treatment of such conditions.

IMMEDIATE ABDOMINAL SECTION.*

By DENSLOW LEWIS, M. D.,

CHICAGO, ILL.

I concur in the opinion, rather freely expressed in certain quarters, that the multiplicity of hospitals in our smaller cities and the superficial familiarity with surgical procedures acquired by the general practitioner who may spend his vacation at one of our postgraduate schools not infrequently result in the performance of an abdominal section by a man who is imperfectly qualified. I deprecate reckless operating by the inexperienced. So many skilled operators are now available in every section of the country that the practitioner is false to the trust reposed in him by his patient if most major operations of election are not performed by the duly qualified alone.

Conceding all this it must also be acknowledged that much of the talk that one hears about "proper surroundings," "a well appointed hospital," "competent assistants," as well as many of the methods in use by some teachers in postgraduate schools foster the idea that there is an attempt at self-advertisement rather than an honest and earnest effort to teach the practitioner-student to operate for himself.

The essentials of asepsis are simple and easily applied everywhere. In an emergency the abdominal wall can be scrubbed with hot soapsuds for a few minutes and wiped dry with a sterile towel. Then there is another washing with alcohol by means of a large piece of gauze, and still another with a bichloride solution. The disinfection of the operator's hands and forearms can be effected in the same manner, the procedure constituting a method in use by some of the most experienced operators of the world, whose results are all that could be asked. The technics of abdominal section is also simple and if properly carried out under aseptic conditions is practically devoid of danger. The incision is preferably in the linea alba, but wherever made bleeding vessels should be caught with forceps and often ligated with fine catgut, so that all hæmorrhage is controlled as the incision is extended. The bleeding vessel in each instance should be seized alone with as little of the adjacent tissue as possible. I have opened and closed the abdomen at least five hundred times without the use of hæmostatic measures of any kind, except forcible compression by gauze sponges and through and through sutures. I do not now favor this procedure. I believe it to be the part of wisdom to save every drop of

blood, for no one can tell how much may be lost accidentally toward the close of the operation, nor can it be denied that every minute blood clot in the abdominal wound is an additional factor of importance as a potential nidus of infection. I also believe it to be advisable to secure accurate coaptation of the several structures of the abdominal wall so that a true *restitutio ad integrum* may really occur. This is only possible by actually bringing together by suture the different tissues so that peritonæum may be apposed to peritonæum, aponeurosis may be reunited to aponeurosis, the continuity of the musculature may be restored, the superficial fascia may be brought together and finally the cut edges of the skin may be accurately apposed without undue tension. For this purpose I favor the use of sterile catgut, which is now obtainable and the separate approximation, preferably by individual suture, of the different tissues which constitute the abdominal wall. I confess I have not always conformed to this theory. Some fifteen years ago I removed a large fibroid in the Presbyterian Hospital of Chicago, and at the autopsy I found pus along the continuous suture which united the peritoneal incision. The very means adopted as a precaution to secure additional safety was a factor in the fatal result. I believe, however, that to-day reliable catgut is obtainable and I prefer its use in all abdominal work. When the operator prepares his own catgut I recommend immersion in a 1 to 1,000 watery solution of mercury bichloride for six to eight hours and subsequent immersion for twenty-four hours in a similar 1 to 2,000 solution. The catgut should then be placed in absolute alcohol to which a little glycerin has been added, and in this solution it should remain at least a month before being used. As catgut is manufactured to-day, it is certainly more convenient to keep on hand the sterilized gut hermetically sealed in its tube, which can be broken at the time of operation.

I now invite your attention to the consideration of those conditions where, it seems, the best interests of the patient are conserved by an immediate abdominal section, even by those of limited experience who make no pretension to a knowledge of surgical procedures. The time has come when no practitioner can with justice remain absolutely in ignorance. Every medical man and woman should know how to use a Murphy button and how to sew up an intestine. The supply of dogs and cats in every community is adequate to any demand and a needle holder and a few intestinal needles are easily obtainable. No one can tell when a human life may depend on the

* Presented to the Surgical Section of the Illinois State Medical Society at its annual meeting in Bloomington, May 17 to 19, 1904.

practitioner's ability to do a little scientific sewing. It is simple to reunite the muscular coat and to close the peritonæum by a Lembert suture, but the value to the practitioner of one preliminary experiment on the dog is well nigh incalculable. The Murphy button is easily adjusted, but it can be done wonderfully better if there has been one trial on an animal.

The proposition may be safely advanced to-day that in every case of gunshot, knife, or other traumatism of the abdominal wall, exact knowledge of the actual condition is imperative. The real extent of the injury inflicted can never be accurately determined without proper examination. There is no longer fear that in the event of a prosecution the defense will assert that death is due to the operation rather than to the injury. There is no longer need of the hydrogen gas test to demonstrate intestinal integrity. Unless the injury is superficial, the wound of entrance should at once be enlarged sufficiently to ascertain if the abdominal cavity has been entered. Where there is no penetration it may suffice to cleanse the flesh wound and allow it to heal by granulation. When penetration has taken place, the abdominal contents must be examined systematically to determine the existence and extent of every traumatism.

In such an examination it is usually advisable to make a median incision long enough to permit complete exploration of all abdominal or pelvic viscera that may be injured (1). Bleeding from the vessels of mesentery or omentum can be controlled by ligature, and intestinal perforations can be closed. For this purpose the muscular coats can conveniently be brought together by interrupted sutures, while the peritoneal surfaces are reunited by a continuous Lembert or other suture, which will approximate a relatively large amount of peritonæum. This is the essential factor in intestinal work. The peritoneal surfaces become agglutinated within a few hours and preserve the continuity of the intestine. If traumatism of the omentum is excessive the injured part may often be cut away with advantage. Here, however, the cut edges must be covered with peritonæum, for it is, in my judgment, of first importance in all abdominal work that no raw surfaces be left to form adhesions which may predispose to ileus. It is most desirable in every case that, when all is done, nothing but peritonæum shall be apposed to peritonæum within the peritoneal cavity. All intestinal perforations must be found and closed, and if any portion of the intestinal tract is the seat of multiple perforation the bowel must be resected. For that purpose the Murphy button

is most admirably adapted, both by reason of the ease of its application as well as by the well known good results that have followed its use.

It must be admitted, as Harris has recently explained (2), that unless the abdominal wound is large enough to permit a view of a visceral perforation or other injury, or to take cognizance of the escape of bile or intestinal contents, the only two symptoms which show a definite injury are hæmaturia, which indicates a traumatism of the urinary tract, and hæmatemesis, which is evidence of a wounding of the stomach. I remember one case of gunshot wound seen in the practice of the late Dr. Hoadley on the Fourth of July some thirteen years ago when at the operation, which was performed too late, there were found fourteen perforations, and the abdominal cavity was full of blood. And yet at the time of operation, which was some fifteen hours after the receipt of the injury, the pulse was full, strong, and regular. It is a mistake to think that no internal hemorrhage is taking place unless there is shock, rapid pulse, cold clammy skin, and other characteristic symptoms. As soon as penetration is recognized there should be an immediate abdominal section without regard to symptoms or the patient's condition.

Only very general directions will be attempted in this connection regarding the treatment of perforating wounds of the abdominal and pelvic viscera. As a rule all wounds should be closed by suture whenever possible and the peritonæum should be sewed over all by a Lembert or other seroserous suture. In this manner the effort will be made in the case of the hollow viscera. When the liver, spleen, or pancreas is injured it may be possible to catch and ligate the bleeding vessels or to control the hæmorrhage by ligatures, which include a variable portion of the tissue of the organ. In other cases we resort to gauze packing.

Drainage should be the rule—almost the invariable rule. The hollow viscera, as Tiffany has pointed out (3), contain more or less gas and any quantity of infecting material. Where there is perforation there is danger of contamination, but there is also danger to the peritonæum by too thorough sponging or douching. The part of wisdom in case of the escape of much fecal matter or stomach contents consists in as complete a removal as possible of all visceral contents, with the minimum amount of irritation to the peritoneal serous surfaces. If the toilet is incomplete, if the perforations are multiple or the traumatism extensive—indeed, it is safe to say in nearly every case of injury to the abdominal or pelvic viscera—statistics show that the use of a

few cigarette or Mikulicz drains for perhaps forty-eight hours is preferable to immediate closure of the abdominal wound. The distance from the perforation or other injury to the surface should be as short as possible. Additional openings should be made, if necessary, through the abdominal wall in a convenient location to avoid a long or tortuous channel.

In the consideration of abdominal injuries where there is no penetration—injuries due to falls, blows, kicks, or to lifting, crushing, jumping, straining, or other forms of violence—direct or indirect—it is to be remarked that the treatment should be determined not alone by the conditions of the injury as they are apparent, but also, and perhaps especially, by the recognition of possible sequelæ or complications of a serious character, which statistical study shows are often to be expected. It is impossible to generalize here, but it must be acknowledged that often the extent of the injury cannot be determined without an abdominal section. I venture the assertion that traumatism sufficient to fracture pelvic bones or to cause extreme shock, acute anæmia, rapid pulse, or other untoward symptoms is likely to have produced some serious internal injury which must be sought for (4). If none is found, it cannot be said that an abdominal section, as performed to-day, will have added materially to the risk.

In reference to obstetric practice, I beg leave to state that it was my privilege some two years ago to present a paper by invitation to the Medical Society of the State of New York, in which I considered the traumatisms of pregnancy (5): In the collection of cases during thirteen years, for the preparation of that paper, it was most interesting to observe how frequently, even after an injury which at the time of infliction appeared trivial, there resulted later severe hæmorrhage, extensive suppuration, or a fatal outcome. I beg leave to refer to my views as expressed on that occasion for the consideration of rupture of the uterus, and other accidents of pregnancy which require immediate operative attention. I must, however, in this connection insist on the performance of Cæsarean section in many instances where the woman is otherwise left to die. The technique is simple—especially Olshausen's—and, as I had the honor to explain at the November meeting of the Bureau County Medical Society last fall (6), there is, in my judgment, no longer an excuse for a persistence in futile attempts at delivery in cases where the birth of a living and viable child is improbable, or where there is danger to the mother. Cæsarean section must be re-

garded by every practitioner as a legitimate operation of emergency, and must be undertaken as readily as any other emergency operation. During the puerperium there may also occur complications requiring abdominal section. My views on this subject are expressed in the address on surgery which I had the honor of delivering at the Cairo meeting of this society (7), and my recommendations in case of criminal abortion have been often repeated (8).

Rupture of an ectopic gestation sac means hæmorrhage, and I think I can say that to-day all agree that rational treatment consists in its control as Bernutz and Goupil pointed out many years ago (9). I do not mean that every case demands immediate operation, but I insist that every case shall be recognized, and that undue loss of blood must be prevented even if abdominal section is performed to permit ligation of the bleeding vessels. I appreciate the necessity of alertness to the possibility of this accident by the recent death of the cook in my own family. The woman, some forty years of age, had been in our employ for years, and was a model servant in every way. While I was at luncheon one day she fell suddenly on the kitchen floor. When I saw her, a few minutes afterwards, she had seated herself in a chair and complained of slight abdominal pain. She drank a little water, and unassisted walked up two flights of stairs to her room. I saw her again within ten minutes. She was lying dressed upon her bed and said she felt better. Her pulse was full, strong and regular, and pressure on the abdomen through her clothes elicited no tenderness. I was told it was not the time of her menstruation. She said she thought she had overworked, so I advised her to stay in bed till I could see her again when I came home to dinner. She complained of no pain now, so I left her. Two hours afterwards when I was holding my usual clinic at the County Hospital word was brought to me that she was dead. The autopsy, conducted the next day by the coroner's physician in the presence of Dr. W. A. Evans and others, showed much blood in the abdominal cavity and a ruptured tubal pregnancy of some six weeks. A single ligature would have saved this woman's life. Had the possibility of pregnancy been taken into account, the true condition would undoubtedly have been recognized, and an immediate abdominal section would have prevented the fatal result.

Aside from the accidents of pregnancy and the injuries to which all are liable there are many diseases and complications and sequelæ of diseased conditions which demand surgical inter-

vention or the patient dies. I have recently seen a case of this character which was particularly sad. The patient was a retired doctor and the father of a doctor. When I saw him the third day of his illness my diagnosis was appendicitis, and my advice was an immediate operation, which was refused. I noticed the distention of the abdomen and above all its rigidity, and after some parley I told the patient frankly that in my opinion he had not thirty-six hours to live unless the operation was performed. His son begged him to submit, but the patient asserted that in his younger days he had treated successfully many cases of this character and he preferred to die rather than undergo an operation. Thirty-four hours afterwards he died, and at the autopsy, conducted the next day by Dr. W. A. Evans, a gangrenous appendix was found, which might easily have been removed.

Now I shall not at this time go into an extended discussion of the treatment of appendicitis. I do not believe that every patient who has pain in the right iliac region needs the knife. I know how much benefit is to be derived from high colonic flushing, thorough evacuation, lavage, and Ochsner's starvation method. At the same time it must be admitted that gangrene is often present when the symptoms are not severe, and that foul pus may accumulate about the intestines when fever subsides and the general condition is apparently good. I see but few cases that I do not operate, and while I admit that I have not always been correct in the diagnosis, I can also say that I have never yet operated without finding some pathological condition that warranted surgical intervention. I will also confess that on several occasions I have found an appendicitis that I did not suspect (10). In attempting to give general advice on this subject, perhaps it is well to emphasize the importance of marked rigidity and any approach to extreme shock. These symptoms in connection with the usual history suggest gangrene, and if they persist unduly and the general condition of the patient does not improve, would in most cases indicate operative interference. In cases where an abscess is recognized there can be no question about the advisability of an operation. Here, however, it is often the part of wisdom to open and provide drainage and to do nothing more at the time. To be sure a hernia may result, but that is of small consequence in comparison with the danger of infecting the general peritoneal cavity by injudicious manipulation.

Abscess elsewhere within the pelvis or abdomen may necessitate operative measures or pus may

be discovered where some other condition—perhaps obstruction of the bowels—induces us to operate. For our comfort it is well to remember that in an old pyosalpinx the pus is often no longer dangerous and rupture is not a serious mishap. Abscesses within the pelvis, when discovered by abdominal section, especially if adhesions are firm and numerous, may often be drained advantageously from the vagina, and sometimes counterdrainage is of value (11). In many instances the safest procedure is to stitch the wall of the abscess cavity to the edges of the abdominal wound and thus provide drainage. Abscesses that form between kinks of intestine in the course of peritonitis will probably be best treated by a Mikulicz drain.

At times irrigation is advisable—even continuous irrigation—perhaps in the Fowler position, which consists in the elevation of the head of the bed twelve to fifteen inches from the horizontal (12). It is impossible to generalize, still I confess to an increasing partiality to provide adequate drainage where there is pus, toxins, or debris to be drained away, and I believe in such cases we will all make use of irrigation more often and more systematically than we have done in the past. I cannot believe with Olshausen (13) that drainage is nearly always injudicious or inadvisable. A hot salt solution can, in my judgment, advantageously replace septic matter in contact with peritoneal surfaces, and its value to control inaccessible hæmorrhage as well as to combat the effects of a dangerous loss of blood can be made available by continuous irrigation in addition, when necessary, to its administration by the rectum or by the intravenous or subcutaneous route (14). When severe diffuse septic peritonitis exists, death is almost certain. I believe in the future it will more and more seem advisable to make a sufficient number of openings in the abdominal wall, so that thorough and continuous irrigation may be instituted. Indeed, even in cases when the abdomen is closed, a pint or more of hot saline solution left in the abdominal cavity has been often attended in my practice with the happiest results.

Obstruction of the bowels is, I am convinced, too often a cause of death. We have much to learn in connection with this complication of many conditions, and it is often possible, I am sure, for a timely operation to prove life saving. I was asked a few months ago to operate on a case of Dr. C. P. Stringfield's. I arranged to do so, but five minutes before I entered the hospital the patient died. At the autopsy, which I conducted the same evening in the presence of Dr. String-

field and Dr. Watson, the small intestine was found kinked and adherent to a right pyosalpinx. There had been an apparently mild peritonitis—non-puerperal—and the first untoward symptom was stercoraceous vomiting, which persisted twenty-four hours before the patient died.

(To be concluded.)

ADENOIDS IN THE ADULT.

By DONALD M. BARSTOW, M. D.,

NEW YORK.

ASSISTANT AURAL SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY, SURGEON TO NEW AMSTERDAM EYE AND EAR HOSPITAL, ETC.

It is the writer's belief that, while the literature of adenoids in children is very full, the subject of adenoids in the adult has been much neglected, in both writing and practice. Some two years ago the writer had his attention called to the subject by a series of cases. Since then he has been at some pains to investigate the condition and to watch for its occurrence. As a result of this work he has collected the accompanying list of 57 cases. In every one of these cases a considerable amount of adenoid tissue was found, and the history was such that the relation of cause and effect could be established between the adenoid and the symptoms. In most cases the presence of the growth could be established by posterior rhinoscopy, but sometimes it was necessary to examine the rhinopharynx by digital palpation. The growth varied in size and distribution, but was always of considerable size, and usually sprang from the angle between the roof and the posterior wall of the pharyngeal vault. It was usually soft, pulpy, and friable; particularly so, strangely enough, in the older subjects.

In the accompanying table the cases have been, for greater convenience of study, arranged by decades. Space limits forbid giving a detailed history of every case, but those of special interest are discussed.

TABULATED RECORD OF ADULT CASES OF PHARYNGEAL ADENOIDS OPERATED ON BY THE WRITER DURING THE PAST TWO YEARS.

I.—Ages 20 to 30 years.

It will be seen from this table that: (1) The sexes are nearly divided, taking all ages into consideration. Of the different decades, the third and fourth, especially the latter, show a majority of females, whereas the fifth decade shows a two to one male preponderance.

(2) Of all cases, thirty-five, or sixty-one and four tenths per cent., showed throat symptoms of one kind or another. These varied all the way from nasal obstruction to chronic laryngitis. Twenty-three showed nasal obstruction of such degree that they made definite complaint of it. Many of these presented a greater or less degree of hypertrophy of the turbinated bodies, which was, in all but a

few instances, so much relieved by removal of the adenoid that it practically disappeared, and called for no local attention. A very common symptom was the expectoration of thick, ropy mucus, which was detached and expectorated with great difficulty. The writer believes that this particular symptom, so common and obstinate, is due to adenoids more frequently than to any other cause. This belief is based upon the fact that the results obtained in these cases have been most gratifying.

The following histories have been selected by the writer as being typical, and as tending to show the wide variety of symptoms which appear to have been, in his experience, caused by this condition:

(1) Gertrude H.—, 25 years old, native of United States, married, an actress. Always healthy up to the time of her marriage, seven years ago. Shortly after marriage developed syphilis, which was treated for two years and has never troubled her since then. For about two years she has suffered from nasal obstruction. She has had her nose "burned out" three times, with little or no relief. For about three months she has had a cough, with pain in the left chest, mucopurulent expectoration, and loss of considerable strength and about fifteen pounds weight.

Physical examination: Patient pale and badly nourished. Anterior nares show considerable enlargement of inferior turbinals. Tonsils not enlarged. Posterior rhinoscopy shows a fairly large mass of adenoids, hanging in folds from the upper part of the posterior wall. Larynx negative. At the upper part of the left chest anteriorly, dullness, exaggerated breathing, and a few subcrepitant rales. Sputum showed a few bacilli.

Operation, March 4, 1903. Adenoid removed under cocaine; no hemorrhage, and no particular reaction. Patient was instructed to sleep with widely opened windows, to keep her bowels freely opened daily, and to drink two quarts of milk a day, in addition to her regular diet.

This patient was seen again on the 10th of the following July. She had gained ten pounds, her cough and expectoration had disappeared, her throat was normal, her nasal hypertrophy had gone, and her chest was completely clear.

(2) Meta B.—, 26 years of age, native of Germany, single, dressmaker. Had had discharge from right ear for about four years. For about one year had had attacks of dizziness, pain over right mastoid, and headache. Ear was never quite dry, but discharge varied a great deal in quantity from time to time. She also suffered from nasal obstruction to some extent. On examination the right drum membrane found to be almost destroyed; a probe, passed into the attic, revealed the presence of dead bone, and on withdrawal brought with it a bit of cheesy white material with a foul smell.

A radical mastoid operation was advised, and was performed by the writer on October 20, 1903. The postauricular wound healed well, and cicatrization progressed satisfactorily but slowly in the antrum, attic, and tympanum. There remained, however, a small amount of discharge from the ear. This appeared to come from the mouth of the eustachian

tube, which I had not succeeded in closing at the time of the operation. Therefore, on March 17, 1904, I removed a large adenoid from her pharynx. Two weeks later the ear was perfectly dry, and has remained so ever since. She was last seen on October 18, 1904.

(3) James J. P.—, 27 years old, native of United States. This case is interesting only as having had five operations upon the nose, by different surgeons, without relief. A large adenoid was removed from her throat by me on June 7, 1904, which effected a complete cure of his nasal obstruction.

(4) C. R. Van E.—, 29 years old, native of United States. This case has been already reported by me in the *Medical Record*, No. 1770, page 578.

(5) Hortense K.—, aged 28 years, native of France. This patient had had two attacks of double mastoiditis, from both of which she had recovered without operation. Her nasal obstruction was most extreme. I removed on November 11, 1903, a large adenoid which completely filled the pharyngeal vault. This relieved her nasal symptoms completely, and I am waiting with great interest to see if her ears shall trouble her again this winter.

(6) Maurice S.—, 30 years old; native of United States; bookkeeper. This patient came to me November 24, 1903. He complained of deafness and a feeling of oppression in both ears, which he had noticed for four days. I removed large plugs of cerumen from both ears. This failed to relieve his deafness, and a complete functional examination revealed the following condition: Watch, right 1 inch, left 2 inches; Weber left; Rinné, both ears, C—, negative, C, positive. Both drums retracted and slightly thickened. The pharynx showed some adenoids, tonsils not enlarged, larynx showed subacute catarrhal laryngitis. On November 28, 1903, I removed the adenoid mass. It was about 1 by ½ by ¾ inch in size. Treatment was directed to increasing the mobility of the tympanic membranes and improving their condition. After two months the patient heard the watch at 4 inches, with the right ear, while for the left his hearing distance remained the same as before. This is perhaps as good a result as could be expected, in view of the fact that the tests had shown trouble in the auditory nerve. His improved hearing was noticeable and very gratifying to himself, and he also declared his singing voice to be much improved since the operation.

(7) Bertha E.—, 37 years old; native of United States; married. This patient was one of three with tuberculosis referred to me by Dr. John F. Russell. Her history will do for all of them. She had been under his care for more than a year, and her chest was practically clear of physical signs, although her cough and expectoration continued, her sputum, however, being negative. She had large tonsils, as well as a considerable mass of adenoids. Removal of the growths on June 2, 1904, was followed by speedy subsidence of the cough, and she was shortly thereafter discharged from treatment. Dr. Russell tells me that she has remained well ever since.

Of the three similar cases in the table there is little to be said, except that in all of them a considerable mass of adenoid tissue was found, and that they have all recovered, and still remain well.

TECHNIQUE.

The technique is simple. The patient should be instructed, during forty-eight hours beforehand, to spray the throat every four hours with an atomizer containing Dobell's solution, one part, in water, four parts. This is all the preparation that the writer has found necessary. Indeed, many cases have had their entire preparation at the time of operating, and have given no trouble. Previous to the operation the pharynx is swabbed thoroughly with cocaine crystals, caught up on the end of a cotton wrapped applicator, and dipped in sterile water. Cocaine in such strength as this, by its astringent action upon the blood and lymph vessels, prevents its own absorption, and thus all toxic effects are avoided. For this idea the writer acknowledges indebtedness to Dr. Robert C. Myles, of New York. After allowing the cocaine a few minutes to produce its full effect, the patient is instructed to rest his head firmly against a wall. The tongue is then depressed with a depressor held in the left hand, while with the right a Beckman curette of proper size is inserted behind the soft palate. The cutting edge is carried to the roof of the vault, and with a gentle rocking motion is made to engage the growth. The curette is next carried strongly backward and then downward, cutting off the growth at its base. The curette is then rotated to one side, in order to avoid injuring the soft palate, and is withdrawn quickly from the mouth. The patient now holds his head over a convenient vessel, to allow the blood to flow freely from the mouth and nose. The hæmorrhage is always considerable, but soon stops. It is very rarely alarming.

Where the growth is soft and pulpy, it comes away readily, and can be expectorated without trouble. In many cases, however, the mass contains a firm, tough fibrous core, which cannot be separated by the edge of the curette. In such cases it is apt to hang in the fauces by a fibrous stem. This leads to obstinate and persistent gagging and retching, and is apt to be rather terrifying to the patient. The best instrument with which to deal with such a condition is a Myles tonsil punch. With this the stem can be neatly severed at its base, and the growth removed. It is essential to use some sort of cutting instrument, for to drag the mass forcibly away is to strip the mucous membrane from the posterior pharyngeal wall, leaving a denuded area, which increases very materially the subsequent soreness of the throat, and must necessarily strengthen the probability of subsequent infection. If there is any special reason for fearing infection it is the writer's practice to swab out the pharynx with alcohol on a cotton wrapped probe. Alcohol constricts the blood

and lymph vessels, and thus guards against both hæmorrhage and septic absorption.

The after-treatment is very simple. A spray of Dobell's solution, one part, in water, four parts used two or three times each day is all that is necessary. If the operation is thoroughly done there is no place left for germs to lodge, and consequently there can be no infection. In none of the writer's cases has there been any trouble of this sort.

Secondary hæmorrhage occurred in two of the writer's patients. One a man, 26 years old, had three sharp hæmorrhages, occurring on the third, fifth, and sixth days after the operation. In one of these he bled to syncope. He recovered completely without trouble. There was an obscure family history of hæmophilia. The other case, a woman, 30 years of age, had two quite profuse hæmorrhages within twenty-four hours after the operation. Her condition was at no time alarming, and the bleeding called for no local treatment. She has a slight chronic diffuse nephritis, which has lasted since her childhood, and which gives no symptoms and no sign of its existence except the constant presence of a trace of albumin in her urine. This may or may not have had to do with her hæmorrhage.

CONCLUSIONS.

Adenoid growths in the adult are much more common than is generally supposed.

The condition is a frequent cause of nasopharyngeal catarrh, with dropping back of mucus and frequent clearing of the throat. It is also a frequent cause of nasal obstruction, and is the causative lesion in some cases of apparent hypertrophic rhinitis. The cases tabulated above show that a thorough examination of the nasopharynx should be made in all cases of (1) ear disease and (2) pulmonary tuberculosis.

The treatment is not difficult, and the results are occasionally brilliant and rarely unsatisfactory.

527 MADISON AVENUE.

Ensworth Medical College, St. Joseph, Mo.—
The following graduated from this institution on April 20th:

Albert Andrews, of Grant City, Mo.; Harry M. Butler, of Lyons, Kan.; Joseph H. Buckles, of St. Joseph; George W. Carpenter, of Clarksdale, Mo.; Charles W. Caldwell, of St. Joseph; Richard E. Ferguson, of Maryville, Mo.; Minor H. Gordon, of Easton, Mo.; Orvel G. Hanna, of St. Joseph; James A. Hill, of St. Joseph; Allen R. Holmes, of St. Joseph; Wayne T. King, of Blockton, Iowa; George A. King, of St. Joseph; Carl R. McFarland, of Barnard, Mo.; Clarence L. Miller, of Prairie City, Ill.; Roy R. Miller and Edgar E. Miller, of Mound City, Mo.; Virgil R. Morrison, of Rushville, Mo.; William P. Murray, of Salt Lake City, Utah; Clarence D. Pickett, of Trenton, Mo.; Clemens Rucker, of Falls City, Neb.; Chris M. Sampson, of St. Joseph; A. S. J. Smith, of St. Joseph.

AN OPERATION FOR THE CURE OF CHRONIC BURSITIS, ESPECIALLY ADAPTED TO HOUSEMAID'S KNEE.*

By PHIL. HOFFMANN, M. D.,
ST. LOUIS,

CLINICAL LECTURER ON ORTHOPEDIC SURGERY, MEDICAL DE-
PARTMENT WASHINGTON UNIVERSITY.

More than six years ago¹ I called attention to a simple operation for the cure of chronic serous bursitis, an operation especially adapted to the treatment of the condition known as housemaid's knee, an enlargement of the prepatellar bursa (Figs. 1

FIG. 1.—Housemaid's knee, bilateral: two years' standing

and 3.) Before this publication, the operation had been tested in a number of cases during a period of three years. In view of the fact that most writers still advocate the severe operations of excision and curettage, it may not be amiss, after a ripe experience, again to bring before the profession the simple operation that has been almost uniformly successful in my hands.

The operation consists of puncturing the bursa, thoroughly scarifying its walls, expressing its fluid contents, bringing its walls in contact, and holding them so by means of a compress until their raw surfaces have grown together and have thus obliterated the cavity.

An ordinary tenotome, having a long shank, or

* Presented to the American Orthopaedic Association, June, 1904.

¹ *St. Louis Medical Review*, January 1, 1898.

FIG. 2.—Same case as Fig. 1: four months after operation.

the especially devised instrument illustrated in Fig. 5, is passed into the distended bursa at its base. With the sharp edge its entire inner surface is marked with many fine cuts, after which the instrument is withdrawn and the bursa evacuated of its fluid contents through the small skin incision. A thick, wide pad of gauze is placed over the bursa and firmly bound down with strips of adhesive plaster, overlapping one another and completely encircling the limb from an inch or two above the

FIG. 3.—Housemaid's knee: eighteen months' standing.

upper margin to the same distance below the lower margin of the bursa. Over this a muslin and a crinoline bandage are applied. A pad of cotton

FIG. 4.—Same case as Fig. 3: thirteen months after operation.

should be placed within the popliteal space, beneath the plaster, to protect the prominent hamstring tendons and overlying skin from undue pressure. The raw bursal surfaces should be kept in contact until firm union has occurred. Two weeks are sufficient. The adhesive plaster strips should be renewed or reinforced whenever they appear loose; as a rule, every two or three days.

No anæsthetic need be given, as the operation is

FIG. 5.—The special scarifier.

practically free from pain, except that produced by puncturing the skin. The bursal lining is not very sensitive and the scarifying gives little distress unless the shank of the instrument is rubbed too hard against the wound margin at the point of its entrance through the skin. Patients have frequently expressed surprise at the lack of discomfort during operation. The patient need not be confined to bed or even use crutches during the after treatment, but may attend to almost any tasks, except such as require kneeling, immediately after operation.

To illustrate: One of my first operations was performed upon a newspaper carrier, who had a chronic enlargement of the prepatellar bursa. He entered the clinic carrying his bundle of papers; the limb was immediately scrubbed with soap and washed with an antiseptic solution, the operation performed,

the dressing applied, and, in less than an hour and a half after entering the operating room, the patient was distributing his papers, free from pain, and with only such slight lameness as was caused by the tight bandage restricting motion at the knee. So, too, during my service at St. John's Hospital, I operated successfully upon two young women employed there for heavy housework. Neither lost a day's time, but both attended to all their usual duties, except such as required kneeling, and suffered little inconvenience. These histories are typical and not selected as exceptional.

I have frequently employed this operation in the treatment of distended popliteal and other bursæ, but not with the uniform good results experienced in the treatment of housemaid's knee.

Ideal compression can be made over the anterior knee bursa, which overlies the patella. Not so, however, over popliteal bursæ, which are deeply situated and do not rest upon a smooth, hard surface, such as presented by the patella. Nevertheless, in a number of cases of chronic popliteal bursitis, which would

FIG. 6.—The ordinary tenotome within the bursa.

otherwise have been subjected to excision, a cure has been effected by this method.

In the past nine years I have operated upon 104 cases of housemaid's knee. In two the operation had to be performed twice and in four three times, while in ninety-eight it was primarily successful.

Though having often successfully used an ordinary tenotome, I have devised the special instrument illustrated in Fig. 5, which has at least, some theoretical advantages. As the blade is strongly curved and raised from the shank, its cutting edge can more easily reach all parts of the cavity without interference from the shank. Figs. 6 and 7, which show both an ordinary tenotome and the special scarifier within the bursa, illustrate how the cutting edge of the scarifier fits the surface better than that of the tenotome.

The principle of scarification and pressure has been advocated for the treatment of so called

FIG. 7.—The special scarifier within the bursa.

ganglion at the wrist, but it has never, to my knowledge, been employed in the treatment of chronic inflammation of large bursæ before the operations referred to in my first paper.

Perhaps it will be well to state in closing that the scarification must be thorough, withdrawal of synovial fluid complete, and the compression quite firm to insure success.

3337 WASHINGTON AVENUE.

REMARKS ON THE PROBLEMS CONNECTED WITH THE STUDY OF PULMONARY TUBERCULOSIS; AND SUGGESTIONS OF A NEW PLAN FOR IMPROVING STATISTICS RELATING TO THE DISEASE.

By E. L. SHURLY, M. D.,

DETROIT.

The positive self-assurance with which some medical writers promulgate the ætiology, early diagnosis, curability, and early extinction of pulmonary phthisis, or pulmonary tuberculosis, is enough to strike the mass of self-contained devotees of medical art with terror. True, such enthusiasm is an inspiring spectacle, if properly corralled—like a group of beautiful performing lions in a stout steel cage; but when turned loose by frequent reiteration, it is apt to engender the apprehension expressed in one of Sophocles's apothegms,

Then does men's life become one vast disease,
When once they seek their ills by ills to cure.

It seems, however, that there are yet many unsolved problems connected with the origin and spread of the conditions popularly termed tuberculosis, which, according to the ignorance of the writer, are beyond the present limits of the present state of scientific knowledge. It is undoubtedly a fact that the artificial inoculation of an animal with tuberculous sputum will usually induce tuberculosis in that animal. It is a fact that the artificial inhalation of the dried tuberculous sputum will sometimes in some animals produce the disease, if persistence and special adjunct circumstances are favorable. But such a result is not easy of accomplishment, for even under rather unfavorable circumstances such results may not be obtained—as demonstrated by the escape of so many guinea pigs in laboratories which are thus exposed to sputum laden air.

Is it a fact that the disease is communicable from one individual to another under the ordinary circumstances of life? Undoubtedly there are

cases which have originated in that way. But how many? Probably comparatively few will be found when an analysis is made of all the particulars belonging to the early or antecedent history of the case. Therefore, can pulmonary tuberculosis be properly classed with the communicable diseases, such as smallpox, whooping cough, scarlet fever, etc.?

Is it not a fact that the history of general hospitals and even special hospitals, such as the Brompton, give little or no evidence of pulmonary tuberculosis having spread or contaminated other patients or the attendants?

Is it not a fact that personal and family predisposition are predominating ætiological factors? If not so, why does primary tuberculosis follow so closely the members of families possessing such characteristics and history?

Is it a fact that "tendency" can be accounted for by the acquirement and latent existence in the economy of tubercle bacilli during childhood or youth? Probably not? Only a theory? Why, a theory when innumerable post mortem examinations on children, and also adults, show chalky deposits or fibroid cicatrices in lymphatic glands or lung tissue? Because other diseases—such as measles, scarlet fever, bronchopneumonia, traumatism, etc.—will leave lesions of these tissues which may show just such vestiges.

Is it a fact that the disease is largely spread by the inhalation of disseminated, dried sputum in the streets, public halls, churches, houses, apartments, or by various appurtenances passing from hand to hand or mouth to mouth? Probably not? At least we have no positive evidence as yet in support of this theory. In other words, are there any cases on record which have been unmistakably traced to such specific origin?

It is true that Cornet, Flick, a British commission, and a German commission conducted experiments by the inoculation of guinea pigs with infusions of dust taken from rooms which were or had been occupied by tuberculous patients, with the effect of producing tuberculosis in the animals inoculated. (The result, however, of the work of the British commission was less positive than the others.) These experiments, however, have not been sufficiently confirmed by repetition to mark the demonstration as conclusive. Dr. P. M. Hickey and myself following the same line of experimentation have met with negative results. Besides, it must be remembered, an inoculation test is not fairly comparable with an exposure in a natural way for obvious reasons, since the operation of the natural defenses of the animal are necessarily prevented.

What about the tuberculosis houses cited by Flick, Biggs, and others? Such districts and such houses as they describe are simply filth depots, and consequently breeders of any disease, and certainly of malnutrition. The wonder is that all of the inhabitants thereabout are not afflicted. Indeed if tuberculosis depended entirely upon the tubercle bacillus for its cause, and was a highly communicable or contagious disease, it should, following the usual epidemiological laws, have almost annihilated the population living in such squalor and density.

Are there houses which have harbored one or more tuberculous persons, that have been the means of afflicting subsequently other previously healthy persons? A few such instances are recorded; but whether or not eliminating elements of evidence have been considered has not always been recorded; for instance, in one such event where the *prima facie* evidence seemed conclusive, I subsequently discovered that Case No. 2 and Case No. 3 had each previously suffered more or less with cough; while one case was syphilitic, and the other an alcohol debauchee.

In this connection might be mentioned "cancer houses" where two or more inmates have consecutively been afflicted with cancer. Is this evidence conclusive enough to warrant the assumption that cancer is a communicable or contagious disease? Are all cases of chronic pulmonary disease, exclusive of the cardiopulmonary affections, due to tuberculosis, or the implantation of the tubercle bacillus? Certainly not, according to the clinical history of that large class known as chronic bronchopneumonia, chronic interstitial pneumonia, chronic fibroid pleuropneumonia, etc.

Is it a fact that the tubercle bacillus may be capable of existing under so many different degrees or phases of activity or latency as to account for the various manifestations observed in connection with chronic pulmonary and laryngeal disease? Or, are there, as has been reported, several different families or varieties of the microorganisms, some of which are purely local or almost innocuous in their action, while others are virulent? Or, again, must this organism be associated with either one or more other microorganisms, or special forms of necrotic tissue in order to fulfil its growth or development?

Is pulmonary, intestinal, or laryngeal tuberculosis induced to any great extent, or at all, by the ingestion of milk or beef? What amount of direct evidence have we in support of such a proposition?

Is pulmonary tuberculosis ever or often intro-

duced through the palatal or pharyngeal tonsils? If so, why are cases of primary tuberculosis of the tonsils so very rare?

What is the relation of the pathogenesis of peritoneal, articular, ovarian, and meningeal tuberculosis to pulmonary tuberculosis?

Granting the theory of communicability, how will State sanatoria, which admit incipient cases only, stamp out the disease if the advanced cases are left scattered through the community?

Many more questions could be raised, of course, because, as we know, fools can ask questions which wise men cannot answer. But the writer's object is merely to draw attention to a few points which will seem to invalidate some of the conclusive dogmas which from time to time recently have been expounded. Of course time is a great leveler and will probably place all facts and theories in proper position.

Time evermore looks on,
And sees these things, now overturning some,
And now, within a day, exalting them.

Unquestionably, the greatest barrier to more rapid progress toward the solution of the practical problems besetting this subject is the lack of accurate statistics. In this State and probably in other States of our nation, the statistics regarding the disease popularly known as consumption are very unreliable; necessarily so, because of the difficulty of making an early diagnosis, and more especially on account of the difficulty of gathering the data relating to such cases. There is good reason for regarding the system of "notification to the health boards" under present circumstances, as not only unjust to the patient by virtue of the necessary publicity thereof, but also by leading to more or less prevarication, duplication, and dodging on the part of practitioners in the interest of their patients. For example, bodies of tuberculosis patients, which are to be shipped out of the State, are frequently falsely reported, in order to avoid the State regulations. That some feasible plan for securing reliable statistics relating to pulmonary tuberculosis is an absolute necessity for the solution of the scientific problems at hand, no practitioner will deny. But how to get such information in conformity with the rights of the patient, the public at large, and the practitioner, under our form of civil government, is a serious question. To this end the writer would suggest the following outline of a plan for consideration:

First, let the registered medical profession of the State nominate (by epistolary vote, sent to the secretary of State) nine of their number, from whom the Governor shall appoint three to be-

come a board of review (or a body otherwise named).

Second, this board shall be created by statute (of the legislature) with power to demand and receive reports from all practitioners, containing such practicable data as the board may dictate.

Third, this board's proceedings, books, papers, and files, in so far as the persons reported to them are concerned, shall be wholly in its custody, considered as confidential, and absolutely inaccessible to the public, the press, or the courts.

Fourth, each month this board shall make an abstract of the communications received in schedule or detail form, and transmit such abstract without names to the State board of health, which shall publish the same quarterly for the edification and instruction of the medical profession.

It would seem as though such a plan would meet the insuperable objection of making public any patient's name, family, or clinical history, and give us data devoid of duplication, error of diagnosis, or other common error. Besides, no thoughtful, reasonable physician would object to making reports to such a constituted board.

The writer feels confident that if the vexed questions of the extent of the communicability of pulmonary tuberculosis, and how it really originates—whether always by the dissemination of tubercle bacilli in the dried sputum or otherwise—could be settled, no member of the medical profession would lag in his efforts to cooperate with the health authorities in carrying out restrictive measures.

32 ADAMS AVENUE WEST.

The Kansas State Medical Board has issued licenses to the following physicians:

H. M. Mayer, A. H. Tribble, A. N. Minear, L. C. Cook, A. T. Coffman, O. J. Casto, L. R. Carson, T. H. Craig, Jr., J. H. Buckles, J. B. Blades, O. P. Faires, A. Florian, J. H. Donovan, T. N. Greenwood, E. O. Baker, R. B. Baker, R. B. Brewster, W. L. Hopper, T. R. Hyatt, W. I. Huddle, E. P. Harrison, A. R. Holmes, L. M. Hinshaw, J. F. Heath, J. F. Hughes, F. E. Harvey, C. H. Helman, W. S. Hadinborg, R. W. Hull, T. R. Heath, Z. G. Jones, B. L. Jones, W. W. Johnston, C. F. Kyser, C. C. Keer, C. E. Phillips, J. L. Mahoney, C. M. Miller, F. J. Moennighoff, C. M. McConkey, G. D. M. Lambdin, J. L. Lonszenhiser, H. M. Lint, E. A. Lewis, H. A. Leaming, H. H. Johnston, N. E. Lake, James Mahoney, H. L. Stelle, N. A. Smith, T. J. Smith, C. N. Smith, R. H. Smith, T. E. Schwarz, J. C. Sherrard, W. L. Shelton, Winfred V. Stephenson, R. B. Stewart, A. S. Risser, C. L. Russell, L. W. Roller, F. H. Redmond, J. W. Ridsen, E. Reeves, C. Rucker, F. H. Rhoades, C. A. Neighbors, F. W. Noble, H. A. Nare, B. E. Miller, A. A. Meyer, R. B. Mays, W. B. Munford, H. E. Markhan, F. M. Morrow, C. F. McNair, C. S. Marsh, John W. McGuire, J. A. Newman, Alva Naylor, H. C. Brown, F. H. Bell, C. Jarams, F. W. Allin, R. P. Young, J. O. Williams, H. M. Walker, P. W. Wooley, G. E. White, F. H. White, Mary L. Withrow, T. E. Tipton, C. A. Thomas, F. W. Tretbar.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXVIII.—How would you prevent disease of the vermiform appendix? (Answers due not later than May 15, 1905.)

XXXIX.—How do you treat erysipelas of the face? (Answers due not later than June 15, 1905.)

XL.—What are your views on the obstetrical binder? (Answers due not later than July 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the NEW YORK MEDICAL JOURNAL and PHILADELPHIA MEDICAL JOURNAL (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXVII has been awarded to Dr. T. Haven Ross, of Cato, N. Y., whose article appears below.

PRIZE QUESTION NO. XXXVII.

THE MANAGEMENT OF THE ALCOHOL HABIT.

By T. HAVEN ROSS, M. D.,

CATO, N. Y.

Each case of alcoholic habituation is a rule unto itself in the projection of a campaign against the alcohol toxemia, the rule depending largely on the personal equation. I can, at best, only take the average case of the man who desires to be cured and who will cooperate with the physician voluntarily. The very first procedure is to regulate the diet and hours of rest, approaching as nearly as may be an ideal hygiene. After these matters are reduced to system and the confidence of the patient is to some extent gained, have a frank, manly talk and impress upon him the *vital* importance of avoiding drinking places and companions of convivial tendency. Explain a little—not too much—of the pathological effect of the abuse of alcohol. Show an interest in his daily life—its joys and sorrows—in his business and aspirations. These preliminaries will, of course, be modified by, and changed to suit, his intelligence, sphere of life, stage of disease, and environment. The patient's family or companions, in-

terested in his rehabilitation, must be instructed in their duties toward and care of the afflicted one. The foregoing steps require the exercise of infinite tact and good judgment on the physician's part. Next let us consider the drug portion of the treatment. The mental therapeutics is as important as that of drugs—in fact, the different elements of the proper care of these cases are interdependent; united in proper proportions in varying cases, they are efficacious in the majority. The more mentality the patient can show the easier the rôle of the physician.

First and foremost, clear out the gastrointestinal tract. My preference is for calomel in small ($\frac{1}{10}$ of a grain) doses hourly until free watery stools are secured, then a saline if there is any indication of nephritic trouble. The condition of the liver is most important, and after the preliminary flushing out it *must* be kept active. This is best accomplished with the following combination:

B	Enonymin (brown).....	$\frac{1}{2}$ grain;
	Podophyllum resin.....	$\frac{1}{20}$ grain;
	Ipecac.....	$\frac{1}{8}$ grain;
	Calomel.....	$\frac{1}{8}$ grain;
	Aloin.....	$\frac{1}{12}$ grain.

M.

In each powder, pill, or tablet these quantities are contained, so that the amount given, best at bedtime, may be graduated accurately to the needs of the individual. Give enough to secure one free, natural movement of the bowels daily, some persons requiring much more than others. I often give only half the amount, but give it in all cases *daily*.

For the care and repair of the crippled vital mechanism my two sheet anchors are nitrate of strychnine and ergot, assisted by a safe hypnotic and a good tonic mixture.

The nitrate acts better in these cases than any other form of strychnine. Usually I give one thirtieth of a grain every four hours. This dose may be increased or diminished as required by the circulation or other circumstance. In the dose mentioned it stimulates digestion and tends to reduce the excitability of the brain and spinal cord. It stimulates respiration, the heart, and the vasomotor centres, replaces alcohol as a nerve stimulant, and in some manner acts as a direct "mental" antidote to alcohol—a power for good in competent hands. It is well to remember that this drug is partially eliminated in the saliva, and therefore may accumulate in the system to a harmful extent if carelessly used. Some prefer nux vomica, but in my hands the nitrate of strychnine has been far more satisfactory. As to ergot, any physiologically active preparation will an-

swer. It may be given by the mouth or with the hypodermic needle, as also may the strychnine, in cases of extreme gastric irritability.

I give ergot as often as it may be required to control the circulation. It acts most happily in equalizing the circulation of the blood throughout the body, especially in the brain, and prevents those symptoms that follow the reduction or withdrawal of alcohol. Since using ergot I have not had a case of so called "wet brain." While the action of ergot on the brain and spinal cord is a great desideratum, its effect on the other great organs is most happy by means of the regulation of blood pressure throughout the body. A safe hypnotic is essential, and I use chloretone. It is often needed in from six to twelve grain doses, once or twice in the twenty-four hours during the first two or three days. It is especially adapted to these cases because, aside from its hypnotic power, it is a gastric sedative. A good bitter stomach tonic, containing some iron, completes the drug treatment.

There is much difference of opinion as to whether the alcohol should be withdrawn at once or gradually. Here, again, the personal equation and physical and mental condition should decide. In most cases it is best to stop all alcohol at once. The treatment outlined, properly adjusted, will supply the place of the poison.

A few complications require notice. The irritable stomach is often troublesome. I find that chloretone acts well added to the ordinary gastric sedatives. Delirium is controlled by the ergot and chloretone, and it is seldom that an opiate is required. If opium is needed at any time, never let the patient know what it is. If he is curious, tell him anything but the truth. Where there is kidney weakness or disease I depend much on saw palmetto, hydrangea, and alkalines. In the primary eliminative measures I often give, for a few days, a mixture containing these agents, with or without digitalis, as indicated. As mentioned above, the ergot prevents "wet brain."

After the cure of the addiction has been accomplished, continue the hepatic and general tonics for some time.

Dr. William Lee Howard, of Baltimore, writes:

My experience has taught me that the alcohol habit, either in the form of inebriety or dipsomania, is a symptom of neuronic disorganization. There is always an instability of psychic control. This causes a constant unphysiological condition—faulty metabolism—which further aggravates the condition of the inhibitory forces. There is a constant state of unrest, morbid fear of self, and loss of control over impulses.

In the treatment of the alcohol habit it is the *individual* that must be very carefully studied and treated. In some of these neurotics there is a psychic epileptic equivalent which is expressed by attacks of dipsomania; in the neurasthenic the fearsome feeling of unrest, the "nervousness," is submerged by alcohol, the subject not having lost the sense of the ego, as is the case in the dipsomaniac.

History and heredity enter more largely into the consideration of the treatment of the alcohol habit than into that of any other form of nervous disease. These must be carefully studied. While this is being done all toxic material must be eliminated. In this preliminary treatment much judgment must be used. Neurasthenics do not well stand cathartics, and the physically unfit do not react from the Turkish or Russian baths, yet one or all of these methods must be used in getting the poison out of the nerve cells. With a proper understanding of the individual the alcohol can be withdrawn as rapidly as the toxine is eliminated. Bromides, chloral, morphine, etc., are not needed; in fact, are injurious. In the cases where great restlessness is prominent, the hot pack is of value. With the exception of nitrate of strychnine, use no drugs. I give the strychnine in $\frac{1}{20}$ of a grain doses every three or four hours. All such tonics as coca, etc., are tabooed. It seems scarcely necessary to say that all possible and easily taken and digested food must be given. The feeding is done five or six times a day, and at night. They should be placed on a diet that contains little proteid matter, for it must be remembered that an exclusive proteid diet causes the formation of excessively large quantities of soluble peptones and albumoses, which have an exciting action on the nervous system and constitute a favorable basis for the development of multiple neuroses.

All these patients should be thoroughly impressed with the fact that they are neurasthenics, that they must recognize this state throughout the active periods of their lives, and that alcohol, instead of relieving their nervousness, aggravates it to a point that is dangerous. Don't tell your patient to "use will power" until he has recovered it. Let him understand that you know his nervous condition compelled him to take a drink or two, and that this was like a match to a keg of powder; an explosion took place and you are going to repair the damages. When he realizes that you will work for him instead of praying for him he will have confidence and hope. Use hypnotic suggestion daily for two weeks after you have put him through the process of elimination.

In many cases the use of tobacco will have to be prohibited. The strychnine, $\frac{1}{20}$ of a grain, should be used for three months. A mild purgative water must be taken twice a week, with cold baths every morning, and strict instructions given to avoid all "nerve tonics." Finally, remember, every case is a law unto itself and must be treated accordingly.

Dr. Edwin W. Moore, of Franklin, Pa., writes:

The alcoholic habit presents a twofold method of causation—the one in the habitual and regular drinker and the other in the periodical drinker. The results are the same, though the time required is longer in the first than in the second. The regular drinker who eats and sleeps with his daily potations may withstand the inroads of stomach, liver, bowel, and kidney complications an indefinite time, but so soon as the stimulant has the victory over the food introduction the equilibrium is broken and there is a gastrohepaticointestinal rebellion, with exhaustion of nerve power, from the want of the dynamic force the food elements afford. This condition is quickly brought about in the periodical drinker for the reason that foods are refused and the false nutrition of alcohol reduces the drinker to extreme exhaustion. In each of the resulting conditions the mind is to a greater or less degree involved.

These conditions existing—gastrohepaticointestinal derangement, nervous exhaustion, and mental excitement—suggest a rational treatment. The subject presents the classical evidences of a debauch, such as furred tongue, sordes on the teeth, nausea, vomiting, constipation or diarrhoea, nervous excitement, and abhorrence of foods and usually of alcoholic beverages. With all these evidences your patient has your duty to him mapped out, and the first cry is: Oh, doctor, give me something to make me sleep! By way of suggestion I say: It has taken some time for you to get into this condition, and it will take time to reinstate Nature and give you sleep, but it will come. If possible, I put my patient in bed and apply mustard over the stomach and hot bottles to the extremities, so as to establish a surface circulation and reflexly to relieve nausea and to encourage sweating and the elimination of poisons. I direct small doses of calomel, ipecac, and bicarbonate of sodium to arouse the excretions and to carry off the toxines and to render the stomach and bowels as fairly aseptic as possible. After a sufficient effect is had from these remedies I direct a full dose of sulphate of magnesium to flush out the *primæ viæ*. At the very beginning of the treatment the patient is given beef tea with plenty of red pepper and buttermilk every hour

alternately. If emitted, repeat, as some will be retained. If the heart's action is weak, give $\frac{1}{60}$ to $\frac{1}{40}$ of a grain of strychnine sulphate every six hours.

This comprehends the routine for the first twenty-four hours. The second day finds the patient better, and though he may not have had any restful sleep, he is more quiet and comfortable. On the second day it is usually safe to add sweet milk, a raw egg in milk, with a less quantity of beef tea and buttermilk, and toward the end of the second twenty-four hours, if the stomach will retain it, some milk toast. If necessary, continue the strychnine. The second night the patient generally sleeps fairly well, and on the morning of the third day will relish some mackerel. The cure now goes on by increasing the food allowance and keeping the bowels open.

It is wise to avoid all narcotics, anodynes, and alcoholic stimulants, for the reason the system is starved and demands foods and the elimination of the toxins which have led to the condition. Further, to get the desired effect from any of the above mentioned means requires doses in excess of safety and adds nothing to the cure.

The question is asked, Is there any known way of overcoming the alcoholic habit? Yes, to conquer the habit implies three things: First, decision and the use of the will; second, a change of association and the seeking of a higher moral atmosphere; and, third, the use of a food element, such as beef tea with red pepper, when the awful passion is on. Christianity adds another—a changed purpose in life. This implies a power behind the will and begets a desire for a purer and cleaner environment, loftier ideals, and a nobler ambition.

It is necessary to avoid the first and fatal drink. When the system demands an alcoholic stimulant, if in its stead the subject takes a full draught of hot beef tea well flavored with red pepper, the systematic demand is answered, and this makes it easier to overcome the longing of a perverted appetite for alcohol.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 856.)

Cadinein is the name applied by Haensel to an essential oil obtained by the steam distillation of cade oil.

Caseinalbumose Soap is a composition of mutton tallow and olive oil saponified with caustic soda and caustic potash. After being salted out with potassium chloride, casein is incorporated and the soap superfatted to 7 per cent. The soap

is recommended as an improvement over casein ointment.

Codesol is a syrup of guaiacol with codeine. Ten grammes of the syrup contain guaiacol, 0.2 gramme and codeine 0.02 gramme. The dose for adults is a teaspoonful three or four times daily.

Colchicine, a pure alkaloid of colchicum, has been recently introduced into medicine.

Epinephrin is the name adopted for the active pressor principle of the suprarenal gland, prepared in accordance with the method of the discoverer, Professor J. J. Abel.

Euprotan is the name given to an albuminous nutrient and roborant obtained by heating blood or blood corpuscles with sulphurous acid, adding concentrated ammonia, and then hydrogen dioxide. Two forms of it have been introduced which are designated *alpha* and *beta*, respectively.

Eutannin is a substance of a composition unknown to us which is recommended as an intestinal astringent. It is said to be taken readily by infants and to be useful in acute and chronic diarrhoeas.

Kamakosin is the name of a remedy for round worms, the active constituents of which are said to be kamala and coussin.

Keramin Soap is a soda-potash soap, containing balsam of Peru, clove, and cinnamon oils, which is said to be of particular use in the treatment of eczema, being recommended by Unna for this purpose.

Lecithan is the new name adopted for a special lecithin made by a Swiss firm.

Lecithin Granules are prepared by dissolving lecithin, 5 grammes, and vanillin, 0.25 gramme in alcohol, 40 grammes, and moistening with the solution so formed 440 grammes of sugar granules. After allowing for a thorough moistening the granules are dried at a moderate temperature.

Lecithinogen, which has been recommended in the treatment of a variety of diseases, is said to consist of a 10 per cent. solution of cane sugar in a liquid called "liquor calcii æthyl. hypophosphor."

Lecitogen is a lecithin prepared with cocoa.

Letalbin (lecithalbumen) is described as a yellow, dry, stable powder with the characteristic taste of egg yolk. It contains about 20 per cent. of pure lecithin, 3.62 per cent. total phosphoric acid, and about 75 per cent. albumen. It is adapted as an addition to infant foods, cocoa, etc.

Leukrol is the name given to a substance which has made its appearance in Germany, in the form of a fluid extract and tablets, which it is asserted contains the active principles of certain unknown East Asiatic ranunculaceæ. It is reputed to be useful in the treatment of fluor albus caused by chlorosis.

Lithium Citroquinat has been introduced as a substitute for lithium quinate (urosin) by Dr. Voswinkel, Berlin.

Liverpool Virus is a rat and mouse exterminator made by the incorporated Liverpool Institute of Comparative Pathology, Runcorn, near Liverpool, England.

NEW YORK, SATURDAY, MAY 6, 1905.

THE PHILADELPHIA "SYMPOSIUM" ON PNEUMONIA.

In this issue we present the report of a meeting of the Philadelphia County Medical Society at which there was a notable discussion on pneumonia. It was opened by a New York physician, Health Commissioner Darlington, who gave an outline of the sort of work that he expected of his Pneumonia Commission. Dr. Wilson then read his able paper on The Symptomatology and Diagnosis of Atypical Forms of Pneumonia, which we published in our issue for April 22nd.

Dr. Hare, in his contribution entitled The Medical Treatment of Pneumonia, laid proper stress upon the fallaciousness of deductions based upon the mortality statistics, owing to failure to distinguish the various types of the disease. In a paper with the title of Some Recent Developments in the Ætiology and Pathology of Pneumonia, Dr. Longcope tersely summarized a number of important new features of our knowledge of the subject. The Surgical Complications of Pneumonia was the title of a paper in which Dr. Gibbon dealt in a very practical way with such occurrences as empyema and pulmonary abscess.

The *viva voce* discussion was opened by Dr. Musser, who gave very graphically the salient points of distinction between pneumonia on the one hand and simulating abdominal and intra-

cranial conditions on the other. The discussion was continued by Dr. Roberts, who pointedly set forth the advantage sometimes to be gained by depletion and by saving the patient the strain of resection of a rib in many instances.

Dr. Tyson, Dr. Daland, Dr. Woodbury, Dr. Githens, and the president of the society (Dr. Anders) followed with notable contributions to our practical knowledge of the disease and its management. We commend the full report to our readers, and we may express the hope that diseases of such continual occurrence as pneumonia may often be made the subject of systematic discussion by our medical societies.

THE SCHILLER CENTENARY.

In addition to the heartiness with which all men honor the memory of a great poet, there is for physicians the special interest in that of Schiller by reason of his brief medical career. The hundredth anniversary of his birth was fittingly celebrated in Germany in 1859, but the people of Europe have a way of celebrating the anniversary of a great man's death as well as that of his birth, and accordingly a Schiller centennial is to be observed next week, and not in Europe alone, but in this country as well. The date falls on Tuesday, and that day is to witness the major ceremonies, but we learn that on certain other days there will be commemorative exercises by various organizations; for example, the Vereinigung alter deutscher Studenten in Amerika will hold a "Schillercommers" on May 6th.

Johann Christoph Friedrich von Schiller was born in Marbach, on the Neckar, on November 10, 1759. In 1776, having previously studied law, he began the study of medicine, and in 1781 he was appointed surgeon to a Würtemberg regiment. He does not seem to have had a great liking for medicine; in fact, he appears to have taken it up under pressure exerted by a local potentate. At all events he soon gave it up, to enter upon that grand literary career by which the world knows him. His first important work, *Die Räuber*, had been brought out on the stage and had met with an enthusiastic reception. That fact seems to have encouraged him to risk everything for literature. The outcome justified his determina-

tion, for, though his subsequent life was an almost incessant struggle with financial embarrassment, he gave to the world dramatic and poetic creations that have caused his name to be enshrined with those of the greatest. He died, at the comparatively early age of forty-six years, on May 9, 1805. If his laurels were not those of a great physician, they were at least those of a man who had been tempered by medical study; we repeat, therefore, that medical men will honor his memory with peculiar enthusiasm.

THE ALCOHOL HABIT.

It will be seen that in the papers submitted in answer to our Subscribers' Discussion question No. XXXVII, How do you Manage the Alcohol Habit? little attention has been paid to the after-treatment of the patients. There is hardly a doubt that the chronic alcoholic is deficient mentally or physically, very frequently the latter. We imagine that much could be learned from a systematic physical examination of a patient after active treatment had restored him to a more or less normal condition. As deficient oxygenation may be a powerful factor in leading to the use of narcotic drugs, examination of the respiratory passages seems to be appropriate, and the requisite surgical treatment should be instituted if obstruction is found. Eye strain from astigmatism, hypermetropia, heterophoria, or all of them combined, is well known to be a slight but, from its incessant action, a dangerous drag on the nervous system, but a proper combination of spherical and cylindrical lenses and prisms will quickly relieve it. Slight deafness is an annoyance that should be remedied if possible. The state of the digestion should be carefully inquired into, and the teeth should certainly be put in as good order as possible. Obvious as these measures seem, we understand that even sanatoria devoted to the care of persons addicted to the use of narcotic drugs do not as a rule pay much attention to them.

Since the nature of such addiction seems to depend largely upon the drug within reach, being alcoholic when only alcohol is available, and quickly becoming addiction to morphine or cocaine when the more powerful agents are at hand,

does it not seem probable that alcohol is sought out by the born or educated drug user for its really anæsthetic effects rather than for its stimulating action? Were genuine stimulation sought for, we should have an army of persons addicted to strychnine and digitalis, with the consequent crusades, restrictive legislation, and heavy taxation. Rather, we believe, it is oblivion that is sought by the tortured neurasthenic, who will literally sell his soul for the blessed feeling of anæsthesia which his whiskey brings him. In all ages this desire for forgetfulness has prevailed. We have beautiful and inspired apostrophes to sleep and even in the ancient world what appealed most to the tired man approaching death was the idea that, once across the threshold, he would first take a deep draught of the placid waters of Lethe.

THE EFFICIENCY OF THE MEDICAL CORPS OF THE JAPANESE ARMY AS COMPARED WITH THE AMERICAN MILITARY MEDICAL SERVICE.

While no direct attacks have been made upon the medical officers of the United States army, more especially those engaged in the recent Spanish-American war, in connection with the recent fulsome laudation of the Japanese medical service, inferences uncomplimentary to American surgeons have been drawn in certain quarters. While the record of the Japanese medical service as compared with that of the American army during the recent year has been phenomenal, many of the comments that have been made have been extremely illogical and very unfair to the American army surgeons. It would be remarkable indeed if Japan could be shown to have evolved within a few years men of greater medical and surgical capacity than those produced by this country.

In seeking an explanation for the comparative efficiency of the medical service of the Japanese army, many factors must be taken into consideration, if one would be fair and reasonable. These factors are mainly entirely dissociated from the personnel of the medical corps. It is primarily admitted that political machinations enter so largely into the organization of the military service of the United States in time of war that the

appointment of a certain number of incompetents to positions in the medical corps is inevitable. But, granting that every man who was appointed to the medical service during the Spanish-American war was the best that could possibly be obtained in this country, essentially the same defects in the management of the sick would have been observed. The responsibility for the efficiency of an army medical corps necessarily rests primarily with the government. How our government did its duty in this regard recent history shows only too plainly. There had been practically no preparation for war on the part of the government, and the most neglected department of all was the medical. The importance of proper medical supplies was seemingly minimized by everybody who had an authoritative hand in the conduct of the war. The fountain head of medical authority in Washington was not only tainted by politics, but characterized by a noticeable lack of executive ability and determination.

I will take for illustration the organization of the hospital corps of various regiments. If my own experience was any criterion, the department head at Washington had not the remotest idea of a definite plan of organization. If conflicting orders are admissible as evidence, the obvious deduction is that somebody at headquarters was enacting the rôle of "the bull in the china shop." My own hospital corps was very carefully selected, and comprised only senior students of medicine, physicians, and pharmacists. The twenty-six men comprising the corps were selected from over three hundred applicants, and selected because of their fitness and for no other reason. This corps was broken up by orders from Washington, and another formed, only to be broken up in its turn in similar manner. A third corps was finally formed, which contained very few of the original members selected by me, and was composed mainly of men of no education or adaptability to the service required. The medical department was so involved in red tape that a requisition for medical supplies which was honored within a month after it started on its weary way through "military channels" was a rarity. Had it not been for supplies purchased on State account at Springfield before my regiment left

that city, no medical supplies or hospital tents would have been available for the regiment for nearly a month. Our only hospital tent was a mess tent, which was the private property of the regiment. All this, notwithstanding the fact that the Seventh Army Corps, to which my regiment was assigned, was encamped in one of our large Southern cities.

It will be remembered that the medical department at Washington was opposed to female nurses at the beginning of the war, and quite as strenuously opposed to regimental hospital organizations, despite the protest of medical men who were on the ground, and therefore in a position to know the exigencies of the situation. It will further be remembered that the government finally was compelled to adopt not only female nurses, but also the regimental plan of hospital organization.

As illustrative of the imbecility of whoever happened to be in supreme authority at that time, the establishment of an army camp at Miami, Florida, is pertinent. Miami in the summer time is so insalubrious that, as one of my friends remarked, "a white man cannot live there, and a negro will not." Protests were made by various surgeons, but to no avail. A certain railway and steamship line had influence at Washington, and with the usual result—the camp was established where the traffic would be of most benefit to the aforesaid line. When a large proportion of the command at Miami was down with typhoid fever, the government awoke, not because of any conscientious regard for the welfare of the soldier, but because it is dangerous to get typhoid germs from an army camp mixed up with the popular vote. The resulting combination is sometimes dangerous to the party in power. The camp was finally abolished.

The racial differences between the Japanese and Americans must be given due consideration. The habits of the Japanese in civil life are simple, temperate, and abstemious as compared with those of the average American youth. It is by no means so great a strain upon the Japanese volunteer as upon the American, when called upon for active service, to adopt the routine of camp life or active operations in the field. He is under better dis-

cipline and control than the American volunteer, patient under restraint, uncomplaining, and obedient. There is no method of control which is effective in the case of the American volunteer, and be it remembered that, while my remarks bear upon the American volunteer rather than upon the regular, it is the volunteer and not the regular upon whom we depend in times of serious trouble.

For the edification of those who are all but deifying the Japanese surgeons, I will give an idea of the daily routine of the American volunteer soldier in camp, as I saw him. It must be remembered that this occurred in midsummer, in Florida, where the temperature was sufficiently high to make physical exertion something of a burden. The soldier was given severe daily drills, protracted parades, and long marches, for the purpose of toughening him and preparing him for the Cuban campaign. This was a reflex of the fallacious idea entertained at headquarters in Washington that the proper way to prepare a volunteer from a temperate clime for service in a tropical one was to kill him in a semitropical clime. Attention has not, so far as I am aware, been hitherto called to this point. Various halts would be made on the weary, dusty march in the hot sun, during which the soldier was permitted to drink anything "wet" which might chance to come his way, with a total disregard of the pathological results of the beverage. Having returned to camp, the first thing he did was to hie him to the various booths that had been established about the camp and partake of the numerous concoctions therein sold. It was nothing unusual for a soldier to drink in succession milk shakes, lemonade, and pop, topping these off with a glass of beer from the regimental canteen and a piece of pie from the nearest huckster's stand. Having thus prepared himself for his evening meal, the soldier sat down and partook of beans that were imperfectly cooked and other "strenuous" articles of diet that under proper circumstances would have been very appropriate and nutritious. At least one outbreak of so called ptomaine poisoning from poisoned beef that occurred in the Seventh Army Corps was due to the ingestion of

half cooked and indigestible beans by an entire company.

The most salient feature in the management of the division hospitals was the entanglement of the surgeons in mile after mile of red tape. The chief interest of the executive head of the medical department seemed to centre around the efforts of the United States government to protect itself against future pension claims. The surgeon who gave the most satisfaction to "the powers that be" was the man who kept the official records of the sick and injured most accurately. So far as I was able to judge, the government would have been quite as well satisfied with the services of industrious and accurate clerks as with those of competent medical men, were it not for the influence that neglect of the sick might have had upon the before mentioned popular vote.

The crying need of the medical service of the United States army in time of war is greater authority on the part of the surgeons. When I complained to the colonel of my regiment that the sick list had increased seventy-five per cent. within three or four days after the opening of the regimental canteen, he replied: "The canteen is all right in the regular army, and why not here? Besides, the regiment needs the money." When I remonstrated with officers for digging trenches about their quarters and for other acts which I considered detrimental to the sanitation of the camp, which camp, by the way, was located on the site of an old cypress swamp which had been filled in and devoted to park purposes, my efforts met with the same success as did my opposition to the regimental canteen. Although realizing keenly the evils of the hucksters' stands about the camp, I was not invested with sufficient authority to abolish them.

It must be remembered, in comparing the records of the Japanese medical service with ours, that the climates of Manchuria and Japan are not greatly unlike. There is a vast difference between taking men from civil life and precipitating them into a tropical or semitropical environment and placing them in a climate similar to that of their native habitat. I have already alluded to the fallacious idea on the part of the United States

government that the proper way to prepare a man for service in a tropical climate was to kill him in a climate as nearly similar to the one in which he was to serve as it was possible to obtain. Ordinary intelligence should have suggested to the government that men sent directly from the Northern States to Cuba would tolerate hard work in a hot climate better than men who had been kept for many weeks in army camps in Florida.

If the United States government is desirous of having an army medical department which shall compare with that of Japan, it would be well to begin at the fountain head. Thorough preparation, and especially the concentration of abundant, up to date medical supplies—in the purchase of which boodle should have no part—in centres which present suitable transportation facilities is a *sine qua non*. Surgeons should be given more authority and a freer hand, and should be appointed for their capacity and not for their political pull. Several thousand miles, more or less, of red tape should be eliminated from the medical department and thrown into the ash heap, where it properly belongs.

Last, but not least, the duty of keeping hospital records should not devolve upon the men who are expected to positively care for the sick and wounded. It is admitted that the pension list should be carefully guarded. If it is not, some deserving soldier may get his just deserts, and a political favorite be crowded out. I do not believe, however, that it is necessary to employ the highest medical and surgical skill for the clerical work incidental to the United States government's system of self-defense.

G. FRANK LYDSTON.

THE OSLER DINNER.

The dinner that was given in honor of Dr. William Osler on Tuesday evening was a noteworthy event. As was to be expected, it was largely attended and the company was representative of the medical profession of North America. The spirit that animated both the guest of honor and those who had gathered to wish him *bon voyage* was of the heartiest. It was not mere courtliness that was shown in the remarks of the various speakers; they thoroughly meant the kind words that they spoke, and it was evident that Dr. Osler himself was deeply moved. The presentation of a

copy of *De Senectute* testified as hardly anything else could have done to the mutual esteem of Dr. Osler and his professional brethren of the United States and Canada. We all hope that Dr. Osler will meet in England with the congenial surroundings that he has done everything to deserve.

THE RADIANT TREATMENT OF CANCER.

The best informed members of the medical profession are watching in a conservative state of mind the efforts in progress in various parts of the world to ascertain with some approach to precision the effects of the Röntgen ray and certain other rays upon malignant growths. But the newspapers are not hampered with any such conservatism; even now they are proclaiming as an accomplished fact the cure of a distinguished man whose case has recently been submitted to ray treatment. We should all feel glad if what they are so ready to take for granted were really confirmed, but we cannot for the present avoid the reflection that false hopes are probably being raised in the hearts of many credulous persons. When a cure for cancer is discovered, it will certainly be announced, but false announcements can do nothing but harm.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 8th.—New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); Medical Association of the Greater City of New York; Society of Medical Jurisprudence, New York; New York Medicohistorical Society (private); New York Ophthalmological Society (private); Gynæcological Society of Boston; Corning, N. Y., Medical Association; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private).

TUESDAY, May 9th.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y. (annual); Newark, N. J., Medical Association (private); Trenton, N. J., Medical Association; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Ky.; Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, May 10th.—Medical Society of the Borough of the Bronx, New York; New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital, New York; Society for Medical Progress, New York; Pittsfield, Mass., Medical Association (private); Philadelphia County Medical Society; Lenox Medical and Surgical Society (private).

THURSDAY, May 11th.—New York Academy of Medicine (Sections in Pediatrics and Otolaryngology); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the

County of Cayuga, N. Y. (annual); South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, May 12th.—Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, May 13th.—Obstetrical Society of Boston (private).

NEW YORK.

Change of Address.—Dr. Frederick E. Beal, to 76 West Eighty-fifth Street.

A Dinner to Dr. Emmet.—A dinner in celebration of Dr. Thomas Addis Emmet's seventy-seventh birthday will be given at Delmonico's on Monday, May 29th.

Infectious Diseases in New York.—We have not received any report from the Health Department regarding the cases of infectious disease for the week ending April 29th.

Personal.—Dr. L. Pierce Clark, of New York, has been appointed consulting neurologist for the Craig Colony for Epileptics.

Dr. John H. Borden, of New York, has been appointed from the civil service list as assistant in the clinical laboratory of the Pathological Institute on Ward's Island.

Dr. Frank Wickham, registrar of vital statistics for the borough of Queens, has been retired on his own application and placed upon the pension list.

Willard Parker Hospital.—Plans have been filed for the enlargement and remodelling of the main building of the Willard Parker Hospital, in Sixteenth Street, east of Avenue C. A three story extension 38 feet wide and 78 feet long is to be added on the front and rear, new fireproof staircases are to be built, and a new up to date plumbing plant installed throughout the reconstructed building. The new construction work is to be fireproof.

St. Mark's Hospital.—Dr. Carl Beck, president of St. Mark's Hospital, announced on April 29th at the semiannual graduation of nurses from the training school, that this year, for the first time in its history, the hospital has been able to pay its own way. He made a plea, however, for funds to establish better quarters for patients and nurses. "We believe in the expansion policy," he said, "and we are waiting for the great Carnegie or Rockefeller to give us the money we need." Nine young women graduated.

Society of the Medical Inspectors of the City of New York.—A stated meeting will be held on Tuesday, May 9, 1905, at 8.30 p. m., at the Chemists' Club, 108 West Fifty-fifth Street. Order: Executive Session; papers of the evening: The Importance of Prophylaxis in the Diseases of Children, by Dr. Floyd M. Crandall; The Physical Examinations of School Children by the Department of Health Medical Inspectors, and What May be the Ultimate Results, by Dr. John J. Cronin. General discussion of these papers by members and guests. A. C. McGuire, M. D., presi-

dent; Edward M. Thompson, M. D., secretary, 315 West Fifty-eighth Street.

Tenth Anniversary of the Medical Class of 1895, New York University.—On Tuesday, May 9, 1905, at 8 p. m., the tenth anniversary of the graduation of the class of 1895 of the medical department of New York University will be fittingly celebrated in a reunion and banquet to be held at the St. Regis Hotel, Fifty-fifth Street and Fifth Avenue. Four members of the class have departed this life in ten years. Ninety-seven are left, of whom seventy-five are expected to be present. Dr. E. Foskett, of 314 West Eighteenth Street, is chairman, and Dr. J. Carlisle DeVries, of 34 West Thirty-eighth Street, is secretary of the committee having the matter in charge.

New Hospital Planned.—Assemblyman Hackett, of New York, succeeded in passing through the Assembly on April 26th his bill for the establishment of a hospital in New York, between Twentieth Street and Forty-second Street, to accommodate 700 persons. The Board of Estimate and Apportionment is to acquire the site in a district on the West Side, shall secure plans and contracts, and equip same with furniture and necessary surgical outfit. Corporate stock is to be issued for payment, and when opened the institution shall be under the same control and administered in the same manner as other city hospitals.

The Medical Association of the Greater City of New York.—A stated meeting of this association will be held in Hosack Hall, New York Academy of Medicine, on Monday, April 10, 1905, at 8.30 p. m. Order of Exercises: Immunity and Infection; Introductory on Immunity, by Dr. Edward K. Dunham; Phagocytosis in Its Relation to Immunity, by Dr. Eugene L. Opie; Therapeutic Value of Antitoxic Sera, by Dr. H. T. Marshall; Therapeutic Value of Bactericidal Sera, by Dr. H. D. Pease; Diphtheria Antitoxine in Cerebrospinal Meningitis, by Dr. Arthur J. Wolff; Limitations of Serum Therapy, by Dr. Henry W. Berg; discussion by Dr. William H. Park, Dr. James Ewing, Dr. Frank Grauer, Dr. James C. Ayer, and Dr. Edward Waitzfelder. J. Lee Morrill, M. D., treasurer; P. Brynberg Porter, M. D., recording secretary, 150 West Eighty-fourth Street.

Margaret Fahnestock Training School for Nurses.—The following young women graduated from this institution on April 25th:

Agnes Cozine Allen, Julie Lydia Ambler, Eva Elizabeth Campbell, Leta Card, Jessie Morrison Christie, Margaret Anna Clark, Elizabeth Donalda Cole, Lizzie Amelia Collins, Edith Macy Cromwell, Irene Eacret, Mary Gardiner, Lillian Adell Hanford, Josephine Hughes, Rosemary Kellner, Ella Camille Ligg, Ruth O'Leary, Louise Burdette Robinson, Florence Margaret Rochotte, Mary Elizabeth Salmond, and Frances Mildred Shore. Champe S. Andrews made an address, Professor James N. West, M. D., presented the diplomas, and Professor Henry D. Chapin, M. D., presented the badges. The reception committee included Miss Ella E. Russell, Mrs. Robert M. Thompson, Mrs. Charles C. Beaman, Mrs. Grant Squires, Mrs. J. W. De Agüero, Mrs. Robert Clarkson, and Mrs. Henry A. Alexander.

A Special Pavilion for Cases of Cerebrospinal Meningitis.—A new pavilion was opened at Belle-

vue Hospital on May 1st for the reception of all cases of cerebrospinal meningitis sent to Bellevue, Harlem, Fordham, and Gouverneur hospitals. While this action was taken partly to relieve the overcrowded condition of the city hospitals the chief purpose is to enable the meningitis investigating commission to study the disease to better advantage. The pavilion holds thirty-five cots. It will be overfilled when the fifteen cases now at Gouverneur Hospital are transferred to Bellevue. Harlem Hospital has sent six cases, while Bellevue already had eighteen. Nine tenths of the sufferers are under ten years of age.

Academy of Medicine.—The Section in Pædiatrics will meet on Thursday, May 11th, at 8.15 p. m. Order: Presentation of Patients: (a) A Case of Retained Intubation Tube Treated by Gradual Dilatation, by Dr. Fielding Lewis Taylor; (b) Two Cases of Hydrocephalus Treated by Autodrainage, by Dr. Alfred S. Taylor; Reports of Cases: Some Cases of Congenital Syphilis, by Dr. Henry S. Patterson; paper: Measures for the Relief of Symptoms in Cerebrospinal Meningitis, by Dr. Francis Huber; discussion; paper: Ulcer of the Stomach in Children, by Dr. William L. Stowell; discussion by Dr. Bovard, Dr. Foote, and others. L. E. La Fetra, M. D., chairman; John Howland, M. D., secretary, 49 East Fifty-third Street.

The Section in Otology will also meet on Thursday, May 11th, at 8.15 p. m. Order: Clinical meeting. All members having patients to present will kindly notify the secretary and send title at earliest possible convenience. Report of a Case of Meningitis Secondary to Otitis Media, with Demonstration of Pathological Findings in Temporal Bone by Microscopical Projection, by Dr. George S. Dixon. Emil Gruening, M. D., chairman; W. H. Haskin, M. D., secretary, 42 East Forty-first Street.

Dinners to Dr. Osler.—Among the entertainments given to Dr. Osler during the week, two dinners figured. The first was given on May 2nd at the Waldorf-Astoria, and was attended by 520 physicians from various parts of the world. It was America's farewell to the distinguished professor. Those who sat the right and left of Dr. Osler were: Dr. James Tyson, of Philadelphia, the chairman of the dinner; Dr. S. Weir Mitchell, of Philadelphia; Dr. W. W. Keen, of Philadelphia; Dr. F. Sandwith, of Cairo, Egypt; Dr. James R. Chadwick, of Boston; Dr. John S. Billings, of New York; Dr. F. J. Shepherd, of Montreal; Dr. A. Jacobi, of New York; Dr. John H. Musser, of Philadelphia; Dr. Edward L. Trudeau, of New York; Dr. Frederick C. Shattuck, of Baltimore; Dr. Stephen Smith, of New York; Dr. Frank Billings, of Chicago; Dr. W. H. Welch, of Baltimore; Dr. J. C. Wilson, of New York; Dr. E. G. Janeway, of New York; Dr. Francis Delafield, of New York; Dr. A. E. Malloch, of Hamilton, Ont.; Surgeon-General George W. Sternberg, of Washington, D. C.; Dr. D. B. St. John Roosa, of New York; Dr. William M. Polk, of New York; Dr. G. K. Dickinson, of Jersey City; Dr. Eugene F. Cordell, of Cleveland; Dr. William B. Gibson, of Philadelphia; Dr. John A. Wyeth, of New York;

and Dr. Robert Fletcher, of Washington. The second dinner followed the annual meeting of the Society of McGill University Graduates, and took place at the Imperial Hotel, May 4th. Many old friends of Dr. Osler were present and the affair was much less formal, if not more enjoyable, than the larger dinner.

PHILADELPHIA.

The Sixth Annual Meeting of the American Therapeutic Society was held at the Hotel Bellevue-Stratford on May 4th, 5th, and 6th.

Hospital Benefit.—As a result of the annual ball, which was held on April 27th, the treasury of Mt. Sinai Hospital will be benefited by the addition of \$2,000.

Marriages.—Dr. Sidney Alexander Chalfont and Miss Edith List were married in Philadelphia on April 24th.

Dr. John Laurence Davies Eisenberg and Miss Mabel Irish were married in Norristown, Pa., on April 27th.

Dr. Alexander MacLeod Brown and Miss Helen Heydrick were married in Franklin, Pa., on April 26th.

Scientific Society Meetings for the Week Ending May 13, 1905.—Monday, May 8th, Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. Tuesday, May 9th, Kensington Branch, Philadelphia County Medical Society; Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, May 10th, Philadelphia County Medical Society. Thursday, May 11th, North Branch, Philadelphia County Medical Society; Pathological Society. Friday, May 12th, Northern Medical Association; West Philadelphia Medical Association. Saturday, May 13th, West Philadelphia Branch, Philadelphia County Medical Society.

Philadelphia County Medical Society.—The following will be the programme of the Philadelphia County Medical Society at its meeting, Wednesday, May 10th: Dr. M. H. Fussell, Two Cases of Malignant Endocarditis; Dr. Norman B. Gwyn, Typhoid Fever; Accidental Infection with the Bacillus of Malignant Oedema or the Gas Bacillus; Death with the Symptoms of Intrathoracic Irritation; Dr. Joseph Price, The Importance of Repairing Cervical and Perineal Injuries at the Termination of the Child-bearing Period; Dr. G. Betton Massey, The Present Aspects of the Cancer Problem. On Wednesday, May 17th, at 8.30 p. m., Dr. Henry Leffman will lecture on Medicine and the Newer Chemistry, under the auspices of the society.

Deaths.—Dr. William B. Ulrich died in Chester, Pa., on April 24th, from the after-effects of influenza. Dr. Ulrich graduated from the medical department of the University of Pennsylvania in 1851 and from the New Orleans School of Medicine in 1866. He was a member of the Medical Society of the State of Pennsylvania and of the Delaware County Medical Society. He was president of the State Society in 1903 and 1904.

Dr. Andrew Douglass Hall died on April 27th, aged 72 years. He graduated from the medical

department of the University of Pennsylvania and from the Jefferson Medical College. For many years he was on the staff of the Wills Eye Hospital.

The Reverend Frederick Wischan, secretary of the board of trustees of the German Hospital of Philadelphia, died in that institution on April 28th of osteomyelitis.

The Health of the City.—During the week ending April 22, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	149	19
Scarlet fever.....	43	0
Chickenpox.....	50	0
Diphtheria.....	66	3
Cerebrospinal meningitis.....	9	4
Measles.....	54	0
Whooping cough.....	10	0
Tuberculosis of the lungs.....	36	60
Pneumonia.....	57	31
Erysipelas.....	5	1
Puerperal fever.....	1	1
Trachoma.....	1	0
Tetanus.....	1	0

The total number of deaths was 455, in an estimated population of 1,438,318, corresponding to an annual death rate of 16.45 per 1,000 population. The total infant mortality was 83; 67 under one year and 16 between one and two years. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 10; dysentery, 2; diarrhoea and enteritis under two years, 10. The temperatures have ranged from a maximum of 79° on the 21st to a minimum of 33° on the 19th. On the 16th there was quite a fall of snow, which did not accumulate, and on the 21st a severe wind and rain-storm at 3.15 p. m., which lasted about fifteen or twenty minutes, and was accompanied by a little thunder. The humidity was not excessive.

State Department of Health.—The governor has signed the bill referred to on page 814 of our issue of April 22nd, known as the State Department of Health Bill. The provisions of this bill have been criticised severely in certain quarters, but it appears to us to be directly in line of modern development in governmental matters—namely, the appointment of a responsible head of executive affairs who shall receive all the credit for good administration and all the blame for poor administration. We quote the following editorial from the *Public Ledger* of April 29th as properly stating the situation:

"The act creating the State Department of Health, which has been approved by the governor, is the most important piece of general legislation accomplished at the recent session. The bill was very carefully drawn, to provide an effective sanitary organization for the whole State. With this end in view, it confers such comprehensive, and often arbitrary, powers, to be enforced by severe penalties, that Governor Pennypacker's approval was by no means assured. Apparently he has satisfied himself that the operations of the new department can be held sufficiently in check by due process of law, or that any dangers of abuse are compensated for by the many conspicuous merits of the act.

"While the department of health, with its executive officer or director, will not supplant the regularly established local boards, it has very large supervisory power over them, and the district health officers, to be under its control, will be the really responsible agents of a general sanitary system. This extends not only to the prevention and treatment of epidemic and contagious diseases, but to the enforcement of general sanitary regulations, the protection of water

courses and other measures of more than local significance. The registration of vital statistics is also within its scope. The whole system appears so well conceived that it will be the fault of the men appointed to administer it if it does not prove of vast advantage and credit to the State.

"It is an inevitable incident of this scientific measure that it falls in with the current of political development. With its centralized power, extending through appointed agents into all sections of the State, it can easily be made a powerful channel of political influence. This consideration doubtless helped to commend the measure to the organization, which is not otherwise especially concerned for the public welfare. Any ulterior purpose of this kind, however, should be defeated by such appointments as we may expect Governor Pennypacker to make. It is he who must determine whether this important new department shall be started right or wrong, and no one doubts his purpose to give to Pennsylvania an honest, enlightened, and skillful administration."

GENERAL.

The Louisiana State Medical Association elected the following officers at their recent meeting: President, Dr. E. H. Martin, of Clarksdale; first vice-president, Dr. R. A. Seal, of Holly Springs; second vice-president, Dr. W. W. Crawford, of Hattiesburg; third vice-president, Dr. Stephen Eggleston, of Greenwood; secretary, Dr. L. T. Fox, of Water Valley.

Alabama Medical Association.—This association closed a four days' session at Montgomery on April 21st, and after selecting Birmingham as the next place of meeting, elected the following officers: President, Dr. E. D. Bondurant, of Mobile; junior vice-president, Dr. Johnston, of Tuskegee; Dr. T. L. Robertson, of Birmingham, and Dr. V. B. Gaines, of Mobile, to succeed themselves on the board of censors.

The Georgia Medical Association has elected the following officers for the ensuing year: President, Dr. William Z. Holliday, of Augusta; first vice-president, Dr. W. B. Hardman, of Commerce; second vice-president, Dr. R. P. Izlar, of Waycross; secretary and treasurer, Dr. Lewis H. Jones. The salary of the secretary was raised to \$600. The convention decided to meet next year at Augusta.

Suffolk County, N. Y., Medical Society.—The Suffolk County Medical Society held its regular spring meeting at Riverhead on April 27th. There were twenty-four physicians in attendance, which was the largest meeting ever held in Riverhead. The following officers were unanimously elected: President, Dr. W. E. Ross, of Brentwood; vice-president, Dr. C. C. Miles, of Greenport; secretary, Dr. Frank Overton, of Patchogue; librarian, Dr. J. H. Benjamin, of Riverhead.

The Medicochirurgical Medical College, of Kansas City, graduated the following on April 12th:

Allan T. Coffman, B. Frank Overstreet, Alfred E. Braden, V. Harvey Greenwood, Thomas W. Scanlon, Harvey M. Mayer, Samuel T. Henshaw, T. Restin Heath, James B. Mercer, Rowland P. Yeagle, Charles R. Zener, Albert H. Tribble, Walter C. Purviance, John C. Lynch, Alney N. Minear, and William H. Mallory.

These two colleges, together with the College of Physicians and Surgeons, of Kansas City, have been amalgamated with the Kansas University. This creates the largest medical school west of Chicago.

Wayne County, Mich., Medicine Society.—The following officers were elected by this society on April 24th: Chairman, Dr. L. J. Hirschman; secretary, Dr. Ray Connor.

St. Lawrence County, N. Y., Medical Society.—At the annual meeting of this society, held at Potsdam on April 15th, the following officers were elected:

President, Dr. Harold J. Morgan, of Ogdensburg; vice-president, Dr. F. J. Fuller, of Potsdam; secretary, Dr. S. W. Close, of Gouverneur; treasurer, Dr. A. H. Allen, of Gouverneur; censors, Dr. R. H. Hutchings, of Ogdensburg; Dr. W. B. Hanbridge, of Ogdensburg; Dr. B. F. Drury, of Gouverneur; delegates to New York State Medical Society: Dr. D. M. Taylor, of Edwards; Dr. S. W. Dodge, of Massena; Dr. H. J. Morgan, of Ogdensburg; Dr. E. M. Somers, of Ogdensburg; Dr. C. C. Bartholomew, of Ogdensburg.

Buffalo General Hospital.—The Buffalo General Hospital and the Ingleside Home will benefit to the extent of about \$30,000 each by the will of Mrs. Mary Stockdale, of Flint, Mich. Mrs. Stockdale died on April 26th, 91 years old, and with no near relatives. Trustees of the Buffalo General Hospital have made inquiries concerning the bequest of that institution. According to a press report, Mrs. Stockdale left about \$30,000 to the hospital. The inquiries which were made elicited the information that the hospital is likely to get \$50,000 instead of \$30,000.

Union Protestant Infirmary, Baltimore.—The following young women graduated as nurses from this institution on April 26th:

Roberta Lee Ball, of Maryland; Beatrice M. Brackenridge, of Maryland; Lulu Braddy, of North Carolina; Edith Child, of Maryland; Olive Irene Doll, of Maryland; Estelle C. Glocker, of Maryland; Maude Montague Gardner, of South Carolina; Agnes Pickett Kloman, of Virginia; Lucy Chilton Kloman, of Virginia; Wie Townsend Lower, of New York; Harriet Nelson, of Maryland; Martha Rutledge, of Maryland; Anne Lowry Semple, of Virginia; Elinore Davis Stuchfield, of Pennsylvania; Mary Turnbull Sims, of Maryland; and Nannie de Dion Wilson, of New York.

Maryland Medical and Chirurgical Faculty.—Officers of the faculty were elected at Baltimore on April 26th, as follows:

President, Dr. Samuel T. Earle; vice-presidents, Dr. Charles O'Donovan, Dr. T. M. Chaney, and Dr. Joseph B. Seth; secretary and treasurer, Dr. Wilmer Britton. The councilors from the Western Shore are: Dr. J. W. Leitch, Dr. T. H. Brayshaw, Dr. Arthur Williams, and Dr. William P. Miller; Eastern Shore, Dr. Paul Jones, Dr. W. F. Hines; Baltimore city, Dr. T. A. Ashby, Dr. R. W. Johnson, Dr. Hiram Woods, Dr. William H. Welch, and Dr. T. S. Latimer. The committee on scientific work and arrangements is composed of Dr. Jeffrey T. Brick, Dr. Arthur Herring, and Dr. John Ruhrah. The committee on public policy and legislation comprises Dr. William H. Welch, Dr. J. W. Chambers, Dr. J. D. Blake, Dr. Samuel T. Earle, and Dr. John Ruhrah.

Meetings of Alumni Associations.—The Alumni Association of the Albany Medical College held its thirty-second annual meeting in Albany on Tuesday, May 2nd. The programme began at 9.30 a. m. and continued all day.

The thirtieth annual meeting of the Alumni Association, Medical Department, University of Buffalo, was held May 3rd and 4th. Members

of the association had luncheon on Thursday noon, May 4th, with Dr. Mann, Dr. Park, Dr. Stockton, Dr. Snow, Dr. Williams, and Dr. Rochester, at the Saturn Club, Delaware Avenue and Edward Street. Out of town alumni were entertained at luncheon by the resident alumni at the University Club, Delaware Avenue and Allen Street.

Statement of Mortality in Chicago for the Week Ending April 29, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	April 29, 1905.	April 22, 1905.	April 30, 1904.
Total deaths, all causes.....	527	558	561
Annual death rate per 1,000.....	13.80	14.56	15.17
Males.....	308	307	324
Females.....	219	251	237
By age—			
Under 1 year.....	121	108	75
Between 1 and 5 years.....	61	67	41
Over 60 years.....	97	109	125
Important causes of death			
Acute intestinal diseases.....	30	17	15
Apoplexy.....	14	15	19
Bright's disease.....	42	40	53
Bronchitis.....	20	25	23
Consumption.....	82	78	62
Cancer.....	30	32	24
Convulsions.....	8	12	6
Diphtheria.....	6	8	8
Heart diseases.....	36	45	45
Influenza.....	0	1	2
Measles.....	9	13	1
Nervous diseases.....	17	18	39
Pneumonia.....	74	72	114
Scarlet fever.....	0	3	7
Smallpox.....	0	2	0
Suicide.....	8	8	7
Typhoid fever.....	3	6	12
Violence (other than suicide).....	21	20	26
Whooping cough.....	27	8	1
All other causes.....	99	135	107

Personal.—Dr. William H. Marcy has been appointed surgeon to the Buffalo fire department.

The Medicopsychological Association, in session at San Antonio, Texas, has made Dr. William F. Bentler, superintendent of the asylum for the chronic insane at Wauwatosa, a member of its executive council to succeed Dr. Moses J. White, superintendent of the Milwaukee Hospital for the Insane.

Major George E. Bushnell, surgeon, has been detailed to represent the medical department of the army at the meeting of the National Association for the Study and Prevention of Tuberculosis, to be held in Washington, May 18th and 19th. Major Bushnell is in charge of the United States General Hospital at Fort Bayard, N. M., established for the special treatment of tuberculosis cases in the army.

Word has been received from Albany announcing the appointment of Dr. F. Park Lewis, of Buffalo, as a trustee of the New York State School for the Blind.

Dr. C. O'Reilly, medical superintendent of the Toronto General Hospital, has severed his connection with the institution. This announcement, which was received with much regret, was nevertheless not wholly unexpected, as it has been for some time understood that Dr. O'Reilly has found the duties of the position growing onerous beyond his strength.

Dr. Henry W. Bettmann was elected president of the Gastroenterological Society at its biannual meeting in New York city on April 26th.

Pith of Current Literature

PRESSE MEDICALE.

April 1, 1905

1. Application of Continuous Extension in Oblique Fractures of the Leg, By L. OMBREDANNE.
2. The Casein Coagulating Ferment and the Digestion of Milk, By LEON MEUNIER.

1. **Continuous Extension in Oblique Fracture of the Leg.**—Oblique fractures of the tibia often produce a considerable deformity on account of the overlapping of the fragments, and to prevent this Ombredanne uses a modification of Hennequin's apparatus to maintain a constant extension.

2. **Digestion of Milk.**—Meunier says that the amount of casein coagulating ferment produced in the stomach varies considerably in different persons in both normal and pathological conditions, and those who have a gastric juice poor in this ferment are subject to gastrointestinal troubles when placed on a milk diet. The chemical study of the digestion of milk and the determination of the coefficient of intestinal utilization of the constituent elements of milk show that there is a distinct relation between the secretion of this ferment and the digestion of fatty material. It regards the passage of the milk along the intestinal tract so that the fat is subjected for a longer time to the action of the saponifying ferments, while at the same time the absorption of fatty material during intestinal digestion is favored. But when this ferment is not present in sufficient quantity the fatty material in the milk is badly digested and this indigestion gives rise to the above mentioned intestinal troubles when persons with this lack in their gastric juice are put on an exclusive milk diet.

LYON MEDICAL.

April 2, 1905.

1. Protection of Infants During the First Year of Life, By Dr. HORAND.
2. Primary Tuberculous Rheumatism, By PAUL CAUTHIER.
3. Congenital Absence of the Right Kidney, By RENE HORAND.

1. **Protection of Children.**—This, the first installment of Horand's exhaustive paper on the subject, deals mainly with the statistics of mortality among infants, chiefly in France, but also as found in other countries. The causes of death at this age are stated as three in number: gastroenteritis, acute diseases of the respiratory system, and congenital debility.

2. **Primary Tuberculous Rheumatism.**—Cauthier reports a case of this nature and concludes with this quotation from Poncet: Acute articular rheumatism is to be distrusted, especially when it resists treatment with the salicylates. Inquire carefully into the antecedents of the patient, his past and present condition, and make use of laboratory processes, experimentation, serum reaction, cytological examination, etc. Think the more of tuberculosis in that no definite

infectious cause has been discovered for this rheumatism, and that it occurs in children and young people.

3. **Congenital Absence of the Kidney.**—Horand reports a case in which the following conditions were present. The right kidney was absent, the left lobulated and hypertrophied, but otherwise normal. The right ureter was permeable and connected with the left kidney, the left atrophic and permeable only at its vesical orifice. The right suprarenal capsule was present, but very atrophic and supplied only by small vessels, the left capsule was of normal size and well formed. The renal vessels on the right side were absent. The right seminal vesicle was normal. Its canal lay normally in front of the ureter to the inguinal canal. The right testicle and epididymis were present. The left seminal vesicle was absent; its canal passed in front of the left ureter, with which it seemed to communicate through the inguinal canal. The left testicle and epididymis were well developed.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE

February 26, 1905.

1. A New Method of Serumtherapy in Syphilis, By M. BOSSI.
2. The Relations of Chloroform Narcosis to the Elimination of Urea Nitrogen, By NICOLINO FEDERICI.
3. The Fallacies of Freund's Method for the Determination of Sulphuric Acid, By EMILIO PITTARELLI.
4. The Epidemic and Polymorphous Course of an Infection Presenting the Characters of Streptococcus and Staphylococcus Infection, By GIOVANNI MORELLI.
5. Iodine in Typhoid Fever, By GIUSEPPE CAMPANELLA.
6. The Treatment of Tetanus, By ADRIANO GIANELLI.

1. **Serum Therapy in Syphilis.**—The new treatment which was tried by Bossi, of the obstetric clinic of Genoa, consists in the use of the serum of mothers who had given birth to syphilitic children. The rationale of this treatment is based on Colles's law, which affirms that a mother who has given birth to a child with hereditary syphilis (of paternal origin) remains free from syphilitic infection. As yet, the results are not sufficiently definite to allow of a positive conclusion, but the author is conducting other experiments on the same line, and calls attention to the new method of treatment, hoping that other observers may be induced to try it.

2. **Urea and Chloroform Anæsthesia.**—Federici uses the ureometer of Fiori for the determination of the amount of urea eliminated in the urine after chloroform anæsthesia. He found that, during the first and second days after the operation, the amount of urea excreted is diminished, and that it again is increased on or about the sixth or seventh days. Inasmuch as the decrease of urea eliminated in the worst cases is but slight, the author thinks that chloroform anæsthesia does not produce such serious or such frequent disturbances in the renal function as is supposed.

3. **Iodine in Typhoid Fever.**—Campanella employed iodine in the form of hypodermic injections in the treatment of typhoid fever with the idea

of directly combating the action of the bacillus. He bases his treatment upon the experiments *in vitro* performed by Cavazzani, and the tests in lower animals by Brunazzi and Lucchesini, who demonstrated the antiseptic and antitoxic virtues of iodine in typhoid infections. In this case Campanella injected one centigramme of metallic iodine, according to Durante's formula, into the subcutaneous tissues, and was gratified to find that the temperature had fallen one degree on the same evening. The injections were repeated daily, and after six days, the patient entered into convalescence. A general improvement in his condition was noted from the time the injections were begun.

RIFORMA MEDICA.

March 25, 1905.

1. Researches on the Metabolism of Chronic Leucæmia (*To be concluded*), By FRANCESCO DE GRAZIA.
2. On the Significance of Intestinal Putrefaction, By ALBERTO ROVIGHI.
3. Infantile Tabes, By AUGUSTO GIANELLI.
4. Specific Changes in the Blood Serum as the Result of the Injection of Various Sputa, By CARLO QUADRONE.

2. **Significance of Intestinal Putrefaction.**—Rovighi's article contests the views recently uttered by Albu, that intestinal putrefaction presents little that has any clinical significance, and is merely of scientific value. The appearance of ethereal sulphates in the urine, according to Albu, is of no special clinical significance. Rovighi shows that a milk diet diminished markedly the amount of putrefactive products in the intestines in patients with an excessive intestinal putrefaction. Milk diet or even a restricted diet is able to diminish considerably the amount of ethereal sulphates passed in the urine. The same is true of a diet consisting chiefly of kefir. The products of intestinal putrefaction, he found, are developed in larger amounts during the day than at night, and more markedly after meals and after the ingestion of large amounts of fluids, although the amount of fluids drunk has no effect on the amount of fermentation in the intestines in health. According to the experiments of Caldesi, a pupil of Rovighi, a cold bath diminishes, while a hot bath increases the amount of putrefaction in the intestines. On the other hand, anything that produces perspiration, such as exercise, e. g., bicycle riding, will diminish the amount of intestinal putrefactive products eliminated, as some of the toxic products are perspired by the skin.

ROUSSKY VRATCH.

March 12 and 19, 1905. (Double Number)

1. The Significance of Heredity in Multiple Exostoses, By N. I. MOUKHINE.
2. The Fate of Salicylic Acid in the Organism, By I. V. ZAVADSKI.
3. On the New Method of Removing the Entire Cancerous Uterus by the Abdominal Route (Modified Wertheim's Operation), By N. M. PROZOROVSKI.
4. Artificial Cultures of the Leprosy Bacillus and Their Action on Animals, By I. I. KLITINE.
5. Emotional Sides of Hypnotism and the Psychotherapy of Alcoholism, By E. P. RADIN.

6. The Limitations of the Operation of Expression in Trachoma (*To be concluded*), By S. A. OLIKHOFF.

1. **Heredity and Multiple Exostoses.**—Moukhine reports the case of a little girl, 8 years old, who had 34 exostoses in various parts of the body. The chief point which he makes in connection with the ætiology of multiple exostoses, is that they may be phenomena of degeneration—that at least in this case they were evidences of physical degeneration. A remarkable feature of this case was the fact that no exostoses could be traced in the girl's ancestors, as far back as they were known. This is not in consonance with the commonly accepted hereditary theory of multiple exostoses. The child presented a number of other marks of degeneration; for example, asymmetry of the cranium, hysterical symptoms, and, above all, retarded development of speech and compulsory motor phenomena, in the shape of involuntary smiles and laughter. These Moukhine, who is a neurologist, regards as of great importance among the signs of degeneration. Thus far exostoses have been studied almost exclusively by surgeons and not by neurologists. Féré is the only author who has recently taken up the neurological aspect of the matter, and he also declares exostoses to be signs of degeneration. Moukhine therefore considers degeneration as the cause of multiple exostoses.

2. **What Becomes of Salicylic Acid in the System?**—Zavadski found that salicylic acid in the body forms double combinations with glycuronic acid or with substances representing the preliminary stages in the formation of glycuronic acid. This combination is very unstable. The question as to what becomes of salicylic acid in the body was first studied by Bertagnini in 1856, this author stating that salicylic acid in the body enters into combination with glyccoll, and is excreted as salicyluric acid. In 1877 Baumann and Herter found that the amount of sulphuric ethers in the urine was increased after the administration of salicylic acid, but they could not isolate the combination which this acid forms in the body.

BOSTON MEDICAL AND SURGICAL JOURNAL.

1. Stricture of the Rectum: A Plastic Operation for the Relief of Certain Varieties, By HOWARD A. LOTHROP.
2. Chronic Gonorrhœal Prostatitis, By CHARLES GREENE CUMSTON.
3. The Employment of the Blind for Massage, By NATHANIEL BOWDITCH POTTER.
4. Chronic Bronchitis in the Adult as Influenced by a Change of Climate, By EDWARD O. OTIS.
5. Evolution and Tuberculosis, By JOHN B. HUBER.

1. **Stricture of the Rectum.**—Lothrop treated a simple annular stricture of the rectum as follows: The rectum was first dissected free from the vagina. By means of two incisions the bowel was cut anteriorly and posteriorly in the line of its axis and at the location of the stricture. The incisions in the bowel were then sutured in such a manner as to bring the line of incision at right angles to the axis of the gut.

2. **Gonorrhœal Prostatitis.**—Cumston has had good results by treating gonorrhœal prostatitis according to the following plan: "Dilate the stricture or strictures, especially those seated in the membranous urethra, proceeding with delicacy so as never to cause hæmorrhage; Secondly, rectal massage of the prostate for from three to five minutes; Thirdly, request the patient to urinate in order to wash out the prostatic urethra and thus remove the secretions that the massage has caused to accumulate there. I believe that this is quite sufficient and preferable to large irrigations of potassium permanganate which are dirty and often produce useless traumatism. Fourthly, instill 1 c.c. or 2 c.c. of a solution of silver nitrate into the prostatic urethra, at the strength 1 to 100 for the first few times and rapidly arriving at 1 to 50. The treatment should be carried out every other day and the length of time that it must be kept up varies very considerably, but I have rarely met with a case where a cure could be accomplished in less than six or seven weeks, and usually about three months is required."

3. **The Blind for Massage.**—Potter urges instructing the blind in the art of massage. This is done extensively in Japan, and to a much less degree in some European countries. In the United States hardly a beginning has been made.

6. The Intercommunicability of Human and Bovine Tuberculosis,
By SILVIO VON RUCK.
7. The Treatment of Gonorrhœal Arthritis by Hyperæmia,
By JOHANNES H. M. A. VON TILING.
8. Smokeless Powders. The Nature and Effects of the Deleterious Gases Given off in Their Explosion,
By CHARLES F. KIEFFER.
9. Local Anæsthesia by Injections of Sterile Water,
By FRANK W. STEVENS.
10. Immunity. Chapter XIV.

1. **Epilepsy.**—Onuf's paper is based on sixteen autopsy cases of epilepsy, in thirteen of which the brain was examined. Even excluding the meninges and blood vessels there was not a case in which the brain was found free from some distinctive organic lesion. The cases are carefully tabulated and a number of photographs of the brains examined are reproduced. The author admits that the cases are too few to serve as material from which to draw formal conclusions, yet the findings must at least be admitted to be suggestive. Starr has held that epilepsy is usually, if not always, an organic disease. The author leaves it to the reader to judge to what extent, if

any, Starr's statement is corroborated by his own studies.

2. **Meningitis.**—Wilson writes a formal paper on meningitis. He prefaces his remarks on treatment as follows: "The mildest cases require no treatment; the malignant cases react to none. Medicine with all its resources is neither capable of combating the attack nor responsible for its results. Of this group of cases Stillé has said 'the first symptoms of the disease are the first phenomena of death.'" A summary of the various methods of treating the disease is then given.

3. **The Colon Bacillus.**—Vaughan concludes: (1) The colon bacillus produces a powerful poison when grown on artificial media. (2) This poison is intracellular in character, and is contained within both the living and the dead bacterial cell. (3) The poison can be separated from the other constituents of the bacterial cell only by means which chemically breaks up the latter. (4) The peritonitis which occurs after intraperitoneal inoculation with the colon bacillus is due to the presence of the poison in a combined and not in a free state. (5) The intracellular poison of the colon bacillus causes a marked fall in the body temperature. (6) The poison of the colon bacillus apparently causes death by paralysis of respiration. (7) The intracellular poison is an essential group of the bacillus, and can be built up synthetically on proteid-free media. (8) This intracellular poison is the poison which causes death in animals inoculated with cultures of the living colon bacillus.

5. **Gout.**—Schmoll propounds a theory regarding gout which accounts for two phases of the disease, (1) the precipitability of the uric acid in the serum and (2) the uric acid deposits in the joint. Normally uric acid results from the oxidation of purin bodies. Thymic acid also is produced, and it combines with the uric acid and keeps it in solution. In gout the uric acid is not only produced by oxidation of purin bases, but also by synthesis; this synthesized uric acid, therefore, has not at its disposal the thymic acid necessary for its solution. It is the reason why we can detect uric acid in the serum. If the formation of the synthetic uric acid increases for one reason or another, there follows a saturation of the serum with this kind of uric acid, and as no thymic acid prevents it from precipitation, it is deposited in the joints as tophi.

7. **Gonorrhœal Arthritis.**—Von Tiling has had good results by following the method recommended by Bier for treating various forms of inflammatory affections by means of hyperæmia. In order to get the best results by Bier's method, it is important not to produce too much constriction by the elastic bandage.

MEDICAL RECORD.

April 29, 1905.

1. Multiple Myeloma (Kahler's Disease). A Contribution to Its Symptomatology and Its Morbid Anatomy,
By JOSEPH COLLINS.
2. Let the Lungs Alone in Consumption,
By WOODS HUTCHINSON.

3. Aerophagia and Flatulence, By C. D. SPIVAK.
4. The Conduct of the Perineal Stage in Normal Labor, By B. A. FEDDE.
5. A Case of Premature Separation of a Normally Situated Placenta, By J. WIRT ROBINSON.
6. Presentation of the Portrait of Dr. Fessenden Nott Otis to the Academy of Medicine of New York, By L. BOLTON BANGS.

1. **Multiple Myeloma.**—Collins reports his case in some detail. Special attention is given to the urinary examinations and to the autopsy protocol. It has been stated that the presence of albumose in the urine is pathognomonic of multiple myeloma. In the present case albumose was never detected in the urine. The most striking clinical features of the author's case follow: There was no deformity or alteration in the contour of the bones to be made out during life. Despite the fact that the substance of the bone was largely replaced by new growth, and the existence of rarefying osteitis to a high degree, there were no indications that there had ever been fractures or dislocations. At no time was albumose found in the urine, and whereas other cases have been reported in which albumose was not found in the urine, this would seem to be the first case which was for a long time under observation in which repeated examination of the urine, extending over several months, during which time the disease was fully developed, failed to find albumose. It is because of this, rather than to discuss the anatomical features of the new growths, that the case is recorded.

2. **Consumption.**—Hutchinson asserts that pulmonary tuberculosis is a general disease with localized lesions in the lungs. It is therefore irrational to devote our attention too exclusively to the pulmonary lesions. The author is inclined to accept the conclusions of Robin and Binet as correct, and to believe that the predisposition to tuberculosis is dependent upon an exaggerated tendency on the part of an individual organism to kill oxygen and form carbonic acid, that is, to consume itself. Treatment must therefore be directed so as to overcome this tendency. Rest and overfeeding are the best measures at our command.

3. **Aerophagia.**—Spivak concludes: (1) Swallowing of air in small quantities is a normal phenomenon. (2) Abnormal swallowing of air may be voluntary (hysteria), and involuntary (dyspepsia, idiopathic). (3) Air may enter the stomach by swallowing, aspiration, or gulping. (4) Cases of aerophagia are not as rare as the earlier writers used to think. (5) Aerophagia, although at the beginning, makes "much ado about nothing," and is, as a rule, a sequel to some other affection, yet when it is not alone it may, in its turn, produce grave symptoms and undermine the health. (6) Aerophagia, tympanites, nervous eructation, pneumatosis, and merycism have an ætiological relationship. (7) The best treatment in voluntary aerophagia is to impress the patient with the fact that he can stop it if he will. For otherwise "they have sown the wind, and they shall reap the whirlwind."

AMERICAN MEDICINE.

April 29, 1905.

1. Adaptation and Tuberculosis, By J. G. ADAMI.
2. Biliary Drainage in Operations on the Gall Bladder and Biliary Ducts, By EUGENE A. SMITH.
3. A Case of Chorea, Fatal, Apparently, from Excessive Muscular Action, By J. P. CROZER GRIFFITH.
4. A Method of Uniting Intestines of Very Small or of Unequal Calibre, By J. SHELTON HORSLEY.
5. Briefs on Genitourinary Surgery, By G. FRANK LYDSTON.
6. Intraabdominal Anastomosis, By A. GROVES.
7. On the Pathogenesis of Lead Intoxication Apropos of the Pathological Findings in a Case, By ALFRED GORDON.

1. **Adaptation and Tuberculosis.**—Adami discusses (1) the adaptation of the organism to the tubercle bacillus and (2) the adaptation of the tubercle bacillus to the organism. What he says of the tubercle bacillus can be said of any other form of microorganism. The theory is this: When a microorganism invades the body and is not immediately destroyed, it produces certain toxins which produce local and general disturbances. The body reacts to the toxins and produces antitoxines and substances which are inimical to the further growth of the invading germs. The offending microorganisms in turn produce defensive substances. Disease of microbic origin reduces itself, therefore, to a struggle between the invaded organism and the invader. Under certain conditions the end result is an increased resistance on the part of the organism to a specific infection and an increased virulence on the part of the invading germ for a like organism.

2. **Biliary Drainage.**—Smith emphasizes the benefits that are to be derived from biliary drainage in operations on the gall bladder and biliary ducts. The author holds that the symptoms in gall bladder and biliary duct disease are due mostly to a toxæmia or septicæmia, and it is for this reason that drainage is of so much importance. He even goes so far as to assert his belief that enlargement, and later, cirrhosis of the liver may be produced by a simple damming back of non-infected bile. A number of cases are briefly reported.

7. **Lead Intoxication.**—Gordon reports the clinical history of a man who died of lead poisoning. An autopsy was done and the affected nerves and the spinal cord were carefully studied. The points which the author believes should be emphasized are: "(1) Involvement of the cells of anterior cornua. Comparatively few cases reported in the literature showed cellular changes. Although the diseased cells are not numerous, they are, however, present. (2) Very slight degeneration in all the nerves and roots; the paralysis of the upper extremities was nevertheless almost complete. (3) Involvement of the posterior roots and posterior columns in the lower cervical and in the lumbar cord. The involvement of tracts in the cord is an infrequent occurrence in lead intoxication. The majority of those cases in which cord changes were found presented

degeneration of a disseminated character. There are, however, a few cases on record showing systemic involvement. Pal, in his work on multiple neuritis in 1891, describes a case of chronic lead poisoning which came to autopsy; polyneuritis of the peripheral nerves with extensive changes in the posterior roots and posterior columns was found. In E. D. Fisher's observation the columns of Goll were sclerosed. E. Redlich's case is one of chronic lead poisoning associated with tabes and verified on autopsy. Carl Bechtold has reported recently a case of spastic paraplegia caused by lead poisoning. The findings in my case are therefore of special interest from the standpoint of the pathogenesis of lead poisoning. It shows that not one theory advanced can be accepted individually, but that several elements play their rôle in the causation of paralysis. With Vierordt, Raymond, and Perrier I think that lead exerts its deleterious influence upon the central tissue, peripheral nerves, and blood vessels simultaneously."

MEDICAL NEWS.

April 29, 1905.

1. A Protest Against Radiological Misinformation,
By HENRY G. PIFFARD.
2. Intramuscular Injections of Insoluble Preparations of
Mercury in Syphilis, By HERMANN G. KLOTZ.
3. A Case of Syphilitic Pseudoparalysis,
By JACOB SOBEL.
4. Two Cases of Gastrostomy with Examination of Stomach
Walls by Means of the Cystoscope,
By R. E. PICK.
5. The Continuous Current in Relation to Inflammatory
Exudates, By MARGARET A. CLEAVES.
6. Rheumatism and the Eye Muscles,
By FRANCIS VALK.

1. **Radiological Misinformation.**—Piffard, by means of a number of quotations from medical books and articles, attempts to prove, what perhaps many have suspected, that there are a number of gentlemen writing on the subject of radiology that are not as familiar with their chosen subject as is desirable from a strictly scientific point of view.

2. **Mercury Injections.**—Klotz is strongly in favor of the insoluble mercury salts for hypodermic administration. He has made in all some 2,500 injections, and has used chiefly the salicylate of mercury. The paper does not touch upon the technics of administration, but is a plea for the more general use of the method. The advantages and disadvantages of the insoluble salts are reviewed.

4. **Gastrostomy.**—Pick's two cases do not present any special features. After the operations the interior of the stomach of each patient was examined by means of a cystoscope. No discoveries were made. The author emphasizes the possible value of this method of obtaining information regarding the inside of the stomach in cases in which an opening into the viscus exists.

5. **Inflammatory Exudates.**—Cleaves asserts that in very many cases, and when all else fails,

it will be found that the continuous current will dissipate inflammatory exudates. Seven illustrative cases are reported. In all were made brilliant recoveries. The types of cases suited to this method of treatment are thus given by the author: Phlebitis, exudative inflammations about the articulations of joints and sheaths of tendons, both rheumatic and septic, pelvic exudates involving the uterus, its mucous lining, and one or both ovaries, the urethra, the bladder, the conjunctiva, the cornea, the membrana tympani, the nasal mucous membrane, the Eustachian tube, the pharynx and tonsils, the intestinal tract, intestinal catarrh, mucomembranous enteritis, the liver, chronic hepatitis, ascites from cirrhosis, perineuritis of the brachial, lumbosacral distribution, etc., and spinal cord lesions, as in tabes and following spinal hæmorrhage. It does not matter what tissue or organ is affected, so long as it is possible to apply electrode contacts, so as to expend the chemicophysical energy of the continuous current directly upon or within the mass of organized exudate. The less fully organization has taken place the quicker and better the result. If it has gone on to the formation of connective tissue bands little can be done for them beyond the improvement of circulatory conditions, softening the morbid tissues, and putting them in a better condition for manipulation by the skilled masseur or for the action of an alternating current.

AMERICAN JOURNAL OF OBSTETRICS.

April, 1905.

1. Hand Sterilization, with Special Reference to the Use of
Oil of Cloves, By WEBSTER.
2. Hand Sterilization by Oil of Cloves, By ROSNOW.
3. Postoperative Complications Involving the Bronchi,
Lungs, Etc., By MILLER.
4. Non-operative Treatment of Eclampsia, By BACON.
5. The Technics of the Operation of Ventrosuspension
of the Uterus, By BEVEA.
6. The Results of Ventral Suspension of the Uterus at the
Johns Hopkins Hospital, By HOLDEN.
7. Cæsarean Section Following Ventral Fixation,
By SMITH.
8. Uncomplicated Varicose Veins of the Female Pelvis,
By MILLER and KANAVAL.

2. **Hand Sterilization by Oil of Cloves.**—Rosnow made experiments in connection with hand sterilization, making cultures (1) before scrubbing, (2) after thorough scrubbing, (3) after both scrubbing and the use of an antiseptic. This was done with, (1) the oil of cloves method, (2) the creolin method, (3) the bichloride method. The cultures were made by scraping epithelium from the skin of the hands and under the nails, and inoculating upon the surface of agar. The results showed great diminution in the number of the bacteria after the use of the scrubbing brush, and still greater after the use of the antiseptics. They also showed (1) that the skin ordinarily harbors many bacteria, (2) that thorough scrubbing with green soap and brush removes many bacteria, but not all, (3) that antiseptics destroy or dispose of a still larger number, and of the antiseptics tested clove oil seemed the most efficient. While it does not destroy all the bacteria in so short a time as

other antiseptics, its volatile and penetrating qualities enable it to reach where the others cannot, and so to destroy the bacteria.

4. Non-operative Treatment of Eclampsia.—Bacon thinks that the present theory that eclampsia means intoxication of the maternal organism with fetal or placental products will, if established, lead to the discovery of a specific serum treatment. Nicholson states that thyroid extract is a specific, but the author thinks this improbable, however valuable it may prove to be. Treatment which is not designed to empty the uterus may be classified as eliminative and symptomatic. The former includes catharsis, diuresis, and diaphoresis, whether by means of drugs, injections, or venesection. The latter includes such means as chloroform, ether, morphine, veratrum viride, lumbar puncture, and oxygen inhalation. Diet, rest, and bodily activity are also influential as means of treatment. The latter, with regulation of elimination, are the principal means for treating the preconvulsive period. A milk diet is suitable for most cases during this period. Rest in bed is almost equally important. Many of the available diuretics must be excluded, because of their irritating effect upon the kidneys. This will exclude the metals, coal tar products, volatile oils, digitalis, aloin, urotropin, and most of the alkaline salts. Excessive ingestion of water is not desirable, but water and salt solutions may be used freely per rectum. For intestinal eliminants we should be limited to calomel, saline cathartics, castor and croton oils, with senna and cascara occasionally. Edema and its effects should be treated by daily sweating. Venesection should be resorted to with great caution. During the convulsive stage treatment should be influenced by the condition of the patient, the severity and number of convulsions, the condition of the child, and the patient's surroundings. With reference to the use of drugs during this stage the author prefers morphine to all others. He does not favor veratrum viride. Lumbar puncture is not looked upon with favor. Oxygen is of great value, and should always be at hand. If convulsions occur after delivery the treatment should follow the lines already suggested; especially should it be supporting and symptoms eliminating. Strychnine and nitroglycerin may be added to the list of drugs which will be serviceable.

6. The Results of Ventral Suspension of the Uterus at the Johns Hopkins Hospital.—Holden gives the following conclusions for 445 cases in which the postoperative history is known: 1. Successful symptomatic results may be expected in 60 per cent. of uncomplicated cases; 2. dysmenorrhea is present with 90 per cent. of nulliparae with retrodisplacement, and with 55 per cent. of multiparae. In uncomplicated cases the dysmenorrhea is relieved by suspension in 50 to 60 per cent. of cases; 3. the suspensory ligament resulting from the operation averages 3.5 cm. in length. After a year its length does not depend on the time elapsing since the operation, or the thickness of the ligament; 4. in most cases there are no adverse symptoms resulting from suspension, dur-

ing pregnancy or labor. Occasionally there is abdominal pain during pregnancy; 5. recurrence of retrodisplacement may occur after labor. In cases in which pregnancy does not result, there are not more than 5 per cent. of recurrences.

7. Cesarean Section Following Ventral Fixation.—Smith draws the following conclusions from cases which have been reported: 1. Ventral fixation is contraindicated during the child-bearing period; 2. if ventral suspension is undertaken, care must be exercised that it does not become a fixation; 3. Alexander's operation or some one of the many varieties of intraabdominal shortening of the ligaments are more suitable operations for women at this period; 4. in severe cases of dystocia from this cause, immediate Cesarean section is preferable to prolonged attempts at vaginal delivery; 5. to prevent recurrence of the trouble the offending band should be removed.

8. Uncomplicated Varicose Veins of the Female Pelvis.—Miller wishes to emphasize the following points: 1. Varicose veins of the blood ligament may be a primary lesion, uncomplicated by other serious conditions; 2. the analogy to varicocele in the male is not proved in the reported cases, beyond the fact of preponderance of left sided cases; 3. a primary varicocele may give rise to a distinct syndrome, upon which a probable diagnosis can be based; 4. as a primary lesion it may demand surgical interference; 5. the treatment consists in ligation and excision or section of the veins with such treatment of the ovaries, tubes, and uterus as may be indicated; 6. the condition may be a factor in causing sclerocystic ovary and subinvolution of the uterus; 7. reports of primary cases uncomplicated by other lesions are desirable; 8. this condition is often secondarily present with retroversion and other pelvic lesions; 9. when present with other lesions recovery cannot be complete until it has been remedied. Correction of the primary lesion is essential, but this will not give tone to the dilated veins, which are a potential if not an active cause of trouble; 10. rupture of the veins may give rise to fatal hemorrhage. This has occasionally been demonstrated, but has probably occurred in other cases in which a diagnosis was not made.

ARCHIVES OF THE ROENTGEN RAY.

March, 1905.

1. Roentgen Rays and Sterility. By BROWN and OSGOOD.
2. Exophthalmic Goitre Reduced by Radium. By ABBE.
3. Notes of a Case of Peripheral Neuritis Treated by High Frequency Currents. By SOMERVILLE.
4. The Importance of Developing the Chest in the Young. By CORNER.
5. The Alcohol Question. By DUTTON.

1. Röntgen Rays and Sterility.—Brown and Osgood call attention to the fact that abrogation of spermatogenesis has been found to occur among those who have worked much in an x ray atmosphere. It is not known as yet to what degree and kind of x ray exposure the worker of average age and health must have experienced before this condition resulted, or whether there is a gradually progressive tendency from the first or a

sudden climax after some particularly long and intense action of the rays. The cases examined show that all who have been working at x rays as a specialty for years, whether physicians or artisans in electrical apparatus suffer with this condition. The question of prognosis is of great importance, but upon this point the authors are not yet prepared to report.

2. Exophthalmic Goitre Reduced by Radium.—Abbe reports a case of this character, undesirable for operation. An opening was made in the tumor into which a tube containing radium was inserted and retained for twenty-four hours. At the end of four months there was still a certain degree of tachycardia, but the tumor had contracted to one sixth of its former size. Two possible explanations of the favorable action are given; there may be retrograde change in all overgrown tissue, or there may be irradiation of the ganglia of the sympathetic, even of the thoracic and cardiac ganglia.

April, 1905

1. On Osseous Formations in Muscles Due to Injury.
By JONES and MORGAN.
2. The Treatment of Epilepsy by X Rays, By MANDERS.
3. A New and Possibly Improved Method of Using Radium,
By LIEBER.
4. A Case of Severe Hysteria Successfully Treated by High Frequency Currents,
By SOMERVILLE.

By BOKENHAM.
6. Note on Sanatoria for Insane Patients,
By MURRAY.
7. The Thyroid Gland. The Influence of Diet on Its Structure and Function,
By WATSON.

2. The Treatment of Epilepsy by X Rays.—Manders states that it is only two or three years since Branth conceived the idea of using x rays for the relief of epilepsy, on the theory that these rays stimulate protoplasm into greater vital activity. He gave three treatments a week, beginning with five minutes' exposure at fifteen inches distance, and increased to ten minutes' exposure at ten inches distance. A different part of the skull was exposed at each sitting. A hard or high vacuum tube, backing up a spark gap of five to eight inches was used. One objection to this treatment is the alopecia which follows it, but the hair will return in a stronger growth than before. It may also be desirable to continue the use of the bromide with the x rays. This treatment is usually followed by a gain in weight, by improvement in enunciation, if that were faulty, and by lighter seizures of shorter duration, and at longer intervals. This treatment is not available if degenerative processes of the brain have begun. A case is narrated in great detail which shows the changes which occurred from day to day under treatment.

3. A New and Possibly Improved Method of Using Radium.—Lieber recalls the facts that recent investigations show that radium discharges primarily emanations and alpha rays only. The emanations soon disintegrate and the disintegrated product gives rise to beta rays, which are

always accompanied by gamma rays. The radiations consist of 95 per cent. alpha rays and 5 per cent. combined beta and gamma rays. The alpha rays and the emanations are lost if the radium is kept in a container. If several layers of radium are superimposed, the upper layers will retain a large percentage of both alpha rays and emanations. Hence a given mass of radium must be of such form that the surrounding walls of the container will not intercept alpha rays or emanations, and it must be spread in such thin layers that practically but one layer exists. The physiological effect of radium rays is frequently far superior to that of x rays. It will determine the presence or absence of blindness, it will change the tissues in sarcoma, carcinoma, lupus, etc.; it also has bactericidal properties upon many varieties of bacteria. The author's production consists in what he terms radium coatings, radium being dissolved and a celluloid rod, or disc, or other instrument being dipped in the solution. The solvent then evaporates and leaves the coating of radium, and this is then fixed with a layer of collodion. The collodion film permits the passage of both alpha rays and emanations. A hollow tube can be similarly coated. This plan enables one to apply radium to any part that is locally accessible.

7. The Thyroid Gland; The Influence of Diet on Its Structure and Function.—Watson states that his object is to show that different diets may cause histological changes in various organs and alteration in their functional activity; this being especially true of the thyroid gland. Two series of experiments were performed, one on fowls, the other on rats. The conclusions which were reached were: 1. An excessive meat dietary induces distinct structural changes in the thyroid gland; 2. these changes must be associated with a modification of the functional activity of the gland. As to the nature of the modification this diet may cause: 1. Excessive activity of the gland followed by diminished activity, or even exhaustion of its function; 2. diminished activity from the outset; 3. alteration in the quality of the secretion, a persistent secretion. The clinical application of these data to the English people, with whom the quantity of meat consumed per capita has increased greatly since 1875, is that as a result of an excessive meat dietary there has been established in many individuals a change in the character of the thyroid secretion. When this change takes the form of a simple deficiency of the thyroid secretions the defect can be remedied by administration of thyroid extract.

INTERNATIONAL JOURNAL OF SURGERY.

April, 1905.

1. Two Cases of Pancreatic Cyst,
By KNOTT.
2. Report of a Few Surgical Cases, with Remarks on Surgery of the Kidney,
By HOLMES.
3. Practical Gynecology,
By SELLMAN.
4. Practical Treatment of Diseases of the Eye,
By COOKE.
5. The Treatment of Movable Kidney,
By GOELLET.
6. Prostatectomy with Union by First Intention,
By DAMERON.

1. **Two Cases of Pancreatic Cyst.**—Knott operated in both these cases. They were differently placed and had different anatomical relations. Neither of them occupied the usual position. Each of them involved the tissues of the pancreas alone. There was disturbance of function in the first case before there was any evidence of cyst formation, while in the second case such symptoms were absent. One of the tumors was spherical in shape, while the other was sausage shaped, expanding into a spherical termination. One operation was incomplete; in the other the entire tumor was removed, but recovery was more rapid in the first of these cases. In the first case the stomach was almost unavoidably wounded; in the second it was not. On the walls of the first cyst was a sticky, grayish, ashlike deposit, while the lining membrane of the second was clean and smooth. In neither case was the skin dry and sallow, as is said to be the case when cyst of the pancreas is present.

MEDICINE

April, 1905

1. The Clinical Value of Fæces Examination,
By SALISBURY.
2. Syphilis as Related to the Problem of Longevity,
By HYDE.
3. The Dunbar Antitoxine Method of Treating Hay Fever,
By STEIN.
4. Simplified Diagnosis,
By HOLLEN.
5. The Treatment of a Case of Severe Burn and Frost
Bite Occurring in the Same Patient, By PERCY.

1. **The Clinical Value of Fæces Examination.**—Salisbury refers to such examinations as analogous to examination of the contents of the stomach. Work in this direction has aimed at the discovery of gallstones, or eggs of parasites, but seldom at the determination of the degree of perfection with which the digestive functions have been performed. The fæces normally consist of the indigestible residue of the food, bacteria, and the remains of the digestive secretions, especially the coloring matter of the bile. If they contain muscle fibres, connective tissue, elastic fibres, free starch, soluble albumen, or fat, digestion has been imperfect. A test diet has been suggested by Schmidt, which shall be perfectly digested by the normal intestines. The resulting stool will be more homogeneous and of lighter color than the previous ones. Urobilin, which is brown in color, indicates the action of the liver secretion upon the intestinal contents, but colorless stools may occur when bile has passed normally into the intestine. Examination of fæces is at present insufficient to throw light upon functional disorders of the pancreas. In studying the fæces for intestinal disorders a gramme of carmine may be given and its subsequent presence noted. Increased peristalsis lessens the quantity of food digested and affects the quantity absorbed. Muscle fibres, plant residues, and mucus stained with bilirubin show disturbed function in the small intestine. Abnormal fermentations indicate disease. They may be determined by Schmidt's or Strauss's apparatus. Pus or mucus from the small intestine is not usually found in the stools. When present it is from the

colon or rectum. Blood from any part of the intestinal canal may be recognized by the Weber test. Examinations of fæces are recommended because of the accessibility of the material, and the simplicity of the methods.

2. **Syphilis as Related to the Problem of Longevity.**—Hyde draws the following conclusions: 1. Syphilis may destroy life, or mutilate and disfigure the body. 2. Skilful, energetic, and prolonged treatment should never be neglected. 3. In inherited syphilis the fatality to ovum, fœtus, and infant amounts to 80 or 90 per cent.; 3. the percentage of fatality in acquired syphilis, where the disease is implanted upon a previously sound organism, is probably less than 2 per cent.; 4. the fatality in acquired syphilis is due less to the active invasion of the disease than to loss of resistance; by which serious effects are produced especially in the nervous system; 5. the efficient factors in producing these effects are chronic alcoholism, tobacco narcosis, extreme fatigue, affliction, malnutrition from poverty, and the stress and strain of business; 6. in the absence of these factors success may be attained in 75 to 80 per cent. of cases of acquired syphilis; 7. the damage from syphilis means not only fatal results, but impairment of the general condition, of the organs, and of the moral sense, and a possible foundation for mental degeneration, alienation, and suicide; 8. the expectation of life after syphilis has been acquired is based in part only upon the tendencies of the morbid process. Such expectation is affected by the inherited tendencies, the habits of life, and the environment. The longevity prospects are better for women than for men.

3. **The Dunbar Antitoxine Method of Treating Hay Fever.**—Stein speaks of Dunbar's demonstration that hay fever is caused by a toxine in the pollen of certain grasses, cereals, and plants. This must be exhibited in an individual who is predisposed to the disease. In seeking a cure Dunbar followed the lines of investigation adopted in other diseases, a serum being finally obtained which would neutralize the toxine. This is prepared in the form of a fluid and of a powder, and is to be dropped upon the conjunctiva or the nasal mucous membrane or both. Its best effects are obtained when given before the onset of an attack. If taken during an attack it modifies, but does not cure it. The serum is very unstable and becomes contaminated almost as soon as exposed to the air.

7. On the Closure of Traumatic Defects of the Skull,

By C. LEEDHAM-GREEN.

1, 2. **Empyema.**—Pringle says that whenever pus exists in the pleural cavity, it should be evacuated at the earliest possible moment. The only result of delay is to give time for adhesions to form between the parietal and visceral layers of the pleura, where they remain in contact, and more or less thickening of those areas where they are separated by the fluid. These conditions form two of the chief causes for the delay in healing and the consequent necessity for secondary operations. The site of the opening through the chest wall is best made in the line of the scapula at the ninth rib; in the supine position this is the most dependent part of the thorax, and affords best and most complete drainage of the cavity. It is usually necessary to remove from one and a half to two inches of the rib, to open the pleural cavity through the centre of the periosteum thus exposed, and to empty the cavity of pus. It is usually best to operate with the patient in the supine position. Before incising the pleura, as much pus as possible should be allowed to run away through a cannula, for the purpose of avoiding a possible sudden dislocation of the thoracic organs and any tendency to collapse that might be induced thereby. The pleura is then to be incised and all fibrin masses washed out. The principle underlying the operation ought to be to get the lung freed from its adhesions and to give it the opportunity to expand if it can, which it will do in all cases unless there are interstitial changes in the pulmonary parenchyma. The process of separation of the adhesions is most easily and safely begun posteriorly where the lung is in contact with the costal pleura. Once started with the finger the separation usually goes on with ease, and the lung can be stripped downwards, and then forwards along the diaphragm, and upwards off the pericardium. In the upper region of the cavity the lung can be freed with a thick metal bougie. As soon as possible the patient should begin respiratory exercises. As regards the treatment of tuberculous empyema and pyopneumothorax, the author holds that many of the cases should have the benefit of operation, but it should be carried out in such a manner that the cavity will be obliterated in the shortest possible time. But no attempt should be made to free the lung from adhesions or to decorticate it. Grünbaum's treatment of chronic empyema consists in the application of a negative pressure to the pleural cavity for several hours every day. The development of a negative pressure of from ten to fifteen millimetres of mercury can be easily maintained by inexpensive apparatus; Fischer's filter pump is almost ideal, because the regulation of the negative pressure developed is easily carried out by altering the length of tube used. The advantages which may be claimed for this treatment are two: the negative pressure tends to expand the lung without necessarily causing emphysema of the other lung, which may be expected from the use of James's bottles. The negative pressure produces a hyperæmia of the tissues of the pleural cavity, which probably increases their local resistance. The comparative opsonic value of exudates from the

pleuræ under normal and under reduced pressures are now under observation.

3. **Treatment of Pneumonia.**—Robson states that the treatment of pneumonia by the alternate administration of acetate of iron and strychnine (where the latter is called for) seems to be particularly useful under the following conditions: 1. Cases of severe bronchopneumonia occurring in infants or children and in catarrhal and lobar pneumonia occurring in debilitated subjects. 2. Where one has not got two properly trained nurses for night and day, respectively, as by the regular administration of the strychnine through the night as well as through the day, the heart's action is kept up, and the danger of heart failure at the crisis is very much lessened. 3. In that infectious, creeping, and spreading form of pneumonia following influenza. 4. The crisis is hastened and favorably modified, the virulence of the disease is lessened, and the complication of empyema seldom occurs. 5. Even when bronchitis is present, there seldom seems need to order depressing drugs like ipecacuanha, as the iron acetate seems to act as a good expectorant.

6. **Biliousness.**—Hare points out that the ætiological factors commonly regarded as responsible for biliousness concur in tending to cause accumulation of glycogen in the liver. Biliousness may be divided into: (1) The acute form, due as a rule to some distinct error of diet, such as a surfeit of plum pudding; (2) the subacute (recurrent) form, due not to isolated indiscretions in diet, but to continued habitual over-indulgence; and (3) the chronic form, usually met with in adults, especially old residents of the tropics, and extending, it may be, to months in duration. Conformably, we may speak of: (1) Acute glycogenic distention of the liver, due to a large sudden irruption of glycogen forming material into the portal venous system; (2) subacute or recurrent glycogenic distention of the liver, in which there is a continued absorption of glycogen-forming material in excess of consumption, and a consequent progressive accumulation of hepatic glycogen, which attains its maximum at more or less regular intervals; and (3) chronic glycogenic distention of the liver, in which recurrent relief fails, and in which consequently the organ remains more or less continuously packed with glycogen. Factors, most of which are admittedly capable of dispersing biliousness, concur in tending to reduce the amount of glycogen in the liver. Some of these may be regarded as therapeutic—namely, abstinence from food, physical exercise, climate, purgatives, restriction of meat and nitrogenous foodstuffs, and restriction of carbohydrates. Others must be regarded as pathological—namely, pyrexia and glycosuria. The rational treatment of recurrent and other forms of biliousness consists simply in limiting the intake of carbohydrate material, and sugar is the first foodstuff to be excluded. Herein is involved no functional impairment in any direction. The treatment consists merely in cutting down excess of supply. But an increase in regular physical exercise must also be advised, in order to obviate the necessity for any severe degree of carbohydrate restriction.

By A. G. R. FOULERTON and V. BONNEY.

1. **Diabetes.**—Bosanquet, in his second Goulstonian lecture, deals with the relationship between the pancreas and diabetes. In animals removal of the pancreas is followed by a condition indistinguishable from diabetes. In man the chief pathological changes found are atrophy, carcinoma, cystic disease, acute and chronic inflammation, calculi affecting the ducts, and hæmorrhage into its substance and into the surrounding connective tissue. It may also undergo fatty degeneration, be the seat of abscess formation, or of total necrosis. Fibrosis of the pancreas is a relatively common lesion, and is often found in association with diabetes. The condition may be correlated with fibrosis of the arterial system and with chronic granular kidney. Diabetes is usually a disease of advanced life, so that its incidence somewhat corresponds with that of pancreatic fibrosis. But fibrosis of the pancreas often exists without diabetes. The rapidity and fatality of diabetes in children suggests the existence of some extensive or progressive lesion of the pancreas. In atrophy of the pancreas in diabetes, it is probably the associated fibrosis which is the principal lesion. Fatty degeneration of the pancreas and the presence of calculi in the pancreatic ducts probably do not exert any direct action on the process of sugar formation. But both may lead to fibrosis, which in turn may be followed by glycosuria. In cancer of the pancreas, glycosuria is not constant—it may appear and pass off. The absence of permanent diabetes is probably due to the fact that the disease does not destroy the pancreatic cells entirely. In cases of hæmorrhage into the pancreas, with complete destruction of tissue, typical fatal diabetes may result, such a case constituting a natural experiment on removal of the pancreas in a human being. It seems to be admitted that hyaline degeneration of the islands of Langerhans is rarely observed, except in diabetes, but it is possible that such degeneration may be a secondary phenomenon. The suggestion of these structures as the source of the internal secretion of the pancreas is a very tempting hypothesis, but even so there remain some cases to be explained in which no alteration of any part of the pancreas can be discovered. Arteriosclerosis is closely connected with diabetes, being responsible for the gangrene

of the extremities seen in diabetics, as well as being one of the assigned causes of the onset of the disease. Syphilis is another cause of pancreatic fibrosis. The frequency of a history of alcoholism in diabetic cases fits in well with the pancreatic hypothesis of its causation—there being a general resemblance to cirrhosis of the liver in this connection. In hæmochromatosis or bronzed diabetes there is probably a functional disturbance of the pancreas. In some cases the pancreas undergoes serious organic changes towards the end of the illness, and true diabetes may result. Nothing is known as to the source of the poison which causes the destruction of the red blood corpuscles.

2. **Spread of Cancer.**—Handley, in his second Hunterian lecture, gives the histological proofs in support of his theory as to the dissemination of mammary cancer: *i. e.*, that cancer of the breast spreads in the parietes centrifugally and by continuity, and that it probably spreads primarily in the plane of the deep fascia where the principal parietal lymphatic plexus is situated, by actually growing along (permeating) the vessels of this plexus. At first permeation spreads only along the lymphatics of medium size; later, the pressure within the permeated lymphatic is increased to such an extent that cancer cells are forced in a continuous line along the smaller branch lymphatics. The parietal metastases of cancer of the breast, however remotely situated, arise in genetic continuity with the primary growth. But the evidence of this original continuity is destroyed by the process of perilymphatic fibrosis. The spreading ring of cancerous permeation usually leaves in its track here and there isolated nodular foci, which give rise to macroscopic nodules.

3. **Cure of Cancer.**—Owen discusses the question as to whether a surgeon is ever justified in claiming that he has cured a patient of cancer. He reports a case of apparent cure of cancer of the breast, but states that in his opinion "no sign of return" is as much as a surgeon is ever justified in claiming as the best result of his treatment of cancer.

5. **Dental Diseases.**—Pedley endeavors to prove that the relationship between dental and other diseases is a very close and intimate one. The defective dentition met with in daily practice and among the poor has the effect, broadly speaking, of lowering the nutrition of the body and by doing so, opening wide channels by which other diseases are only too ready to find their way. Dental disease is the most prevalent of all diseases among civilized communities, and we are as far as ever from touching the cause of this defect. But we have in our own hands the means, not only of alleviating much suffering, but by systematic treatment improving the health, especially of the young who are, in a way, the most important members of the community.

8. **Puerperal Infections.**—Foulerton and Bonney, in their concluding article on this subject, reach the following conclusions: The old classification of cases of puerperal fever into sapræmic, septicæmic, and pyæmic has but little value, as

it is practically impossible to distinguish between mild septicæmias and sapræmias. They would divide the cases into: I. Infection of lacerations of the perineum or vagina; (a) localized infection and toxæmia; (b) localized infection, toxæmia, and generalized infection. II. Primary infection of the contents of the uterus or of the placental site; (a) localized infection and toxæmia; (b) localized infection, toxæmia, and generalized infection. Streptococcic infection is of such predominating importance in puerperal fevers, that in the absence of a definite bacteriological diagnosis the safe course to adopt is to deal with every case of puerperal fever in which the temperature rises above 102° F. as if it were a case of streptococcic infection. For serum treatment to be applied with any reasonable hope of success a polyvalent or compound serum from a horse immunized against the various strains of puerperal streptococci, is necessary. The use of the curette should be absolutely discarded in the treatment of puerperal uterine infection. The uterus should be digitally explored, any retained fragments removed, and the cavity should be douched with an antiseptic solution. Douching the vagina with antiseptic solutions before the commencement of labor is useless, but the statement that it is dangerous, since by such means bacteria may be conveyed from the vulva to the upper part of the vagina, appears to be without foundation.

9. A Review of Recent Work in Obstetrics. *Accouchement forcé*, and Vaginal Cesarean Section, By FOTHERGILL.

1. **Obscure Cases of Cancer of the Stomach.**—Pitt observes that the symptoms in gastric cancer vary with its site. If it is at the pylorus there is obstruction, overdistention, and increased peristalsis. Vomiting, emaciation, and loss of appetite occur and the tumor can usually be felt. If the body of the organ is involved the tumor is palpable, but there is no obstruction or overdistention. Emaciation, pain, and loss of appetite are also present. The development of the disease and its symptoms may be so gradual that the diagnosis of cancer may not be made until at the autopsy. A series of cases of this nature is narrated, the principal symptoms of which were not

associated with the stomach. They were divided into the following groups, according to the predominating symptoms: 1. Ascites and pleuritic effusion; 2. matted intestine; 3. intestinal obstruction; 4. abdominal suppuration; 5. profound anæmia; 6. iliac tumor; 7. thrombosed veins. Œdema occurred in several of the cases, but was not the only abnormal sign. Perforation occurred in two cases. Pyrexia was observed in several cases, but was not a prominent symptom. In none of the cases were there nodules of the skin or bones.

3. **The Treatment of Scalp Ringworm.**—McBride narrates a number of methods of treatment which have more or less enthusiastic advocates. His preference is for the croton oil treatment, which he thinks the most certain and effective of all. He calls attention to the fact that it requires most careful control and cannot be left to inexperienced hands. As practised by him, it consists in the daily application of an ointment which contains one drachm of croton oil to an ounce of a suitable base. It may be used oftener than once a day if necessary to produce a suitable degree of inflammation. The treatment must be continued until all the diseased hair stumps have fallen away or have been epilated. The tissues are kept scrupulously clean, and crusts are not allowed to form. For the treatment of residual and isolated stumps there is no method which will compare with croton oil needling.

5. **The Cytodiagnosis of Pleural and Cerebrospinal Fluids.**—Turton draws the following conclusions: 1. In pleural effusions the cytological formulæ of Widal and Ravant apply to the majority of cases. An excess of lymphocytes points to a tuberculous origin, an excess of polymorphonuclear cells to an inflammatory process, due to infection; 2. the cerebrospinal fluid in meningitis usually shows lymphocytes when of tuberculous origin, the pneumococcus or streptococcus in inflammatory conditions caused by the meningococcus, and by an excess of polymorphonuclear cells in posterior basic meningitis. Cytological examinations enable us to differentiate various forms of meningitis, to distinguish meningitis from typhoid fever and other infectious diseases, and from tetanus and hysterical pseudomeningitis; 3. lymphocytosis is almost constant in general paralysis of the insane, in tabes, and in syphilis of the nervous system, and may be useful in distinguishing these diseases from others which resemble them. General paralysis and tabes may be determined in very early stages by cytological examination. Cytology will also be useful in making an early diagnosis of syphilis. A diagnosis should not be based wholly upon the result of a cytological examination, but this should serve as a valuable link in the chain of clinical evidence.

6. **The Treatment of Diphtheria.**—Nash regards the ultimate pathological conditions in diphtheria as analogous to those produced by serpent venom, the diphtheria toxins working less rapidly. Many cases are also cases of mixed infection. Antidiphtheritic serum should be administered as soon as there is a suspicion that diph-

theria is present. It should be given in a hypodermic injection of 2,000 units on the first day of the disease and not deferred until the bacteriological report is received. It is useful as a preventive; it is useful for sore throat, which is not of diphtheritic origin, and it does no harm if diphtheria is not present. It should not be given by the mouth or rectum. Late administration of antitoxine will prevent further absorption of diphtheria toxins, but it must be given in a double or treble dose if deferred until this time. Strychnine also should be given with tincture of perchloride of iron in much larger doses than are ordinarily prescribed. Rest in bed should be insisted upon from one to three weeks. Milk, beef tea, and eggs should be given three or four days after which the ordinary diet can be used. Complications seldom occur if antitoxine is given early, hence tracheotomy is rarely indicated. The steam tent should be used early. Intubation is preferable to tracheotomy when possible. Nasal feeding may be required. Rhinitis is a frequent complication. The air passages should be douché with solutions of sublimate, lysol, formalin, or permanganate of potassium every four to six hours. The douche may take the form of a nebulizing spray. Treatment is best carried out in a hospital, if it is done at home the patient and his nurse must be isolated, and his room must be freely ventilated.

9. **Recent Work in Obstetrics.**—Fothergill states that the most interesting recent work has to deal with interference during the first stage of labor. They include methods of opening or dilating the cervix, or of gaining access to the uterine cavity without dilatation. Of 82 Cæsarean sections, 20 were performed for eclampsia, placenta prævia, cancer of the cervix, threatened rupture of the uterus, or accidental hæmorrhage. The various devices for opening the uterus have been tabulated by Williams chronologically as follows: 1. Dilatation of the cervix by the hand in the form of a cone; 2. the mechanical devices of Oslander, Busch, and others; 3. Champetier de Ribes balloon and other bags; 4. deep cervical incisions, whether multiple incisions, or vaginal Cæsarean section; 5. Bossi's and other dilators; 6. Harris's method of manual dilatation; 7. bimanual methods of dilatation advocated by Edgar and Bonnaire. Of these the third, fifth, and sixth are most in use. Williams thinks the Harris method of dilatation even more rapid than the method with the powerful Bossi dilator. The vaginal Cæsarean section is preferred by Dührssen to any form of dilatation, as it gives access at once to the uterine cavity and the fetus. It has been performed more than a hundred times, and is a comparatively safe operation. Its indications are: 1. Cancer of the cervix during pregnancy, the operation being followed by vaginal hysterectomy; 2. abnormal conditions of the cervix and lower uterine segment, such as rigidity, fibroma, stenosis, or incarceration; 3. dangerous heart, lung, or renal conditions of the mother; 4. the evident fact that the death of the mother is imminent. It may replace the classical Cæsarean section in eclampsia and all conditions in which the soft parts obstruct labor seriously.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of March 22, 1905.

The President, Dr. JAMES M. ANDERS, in the chair.

"SYMPOSIUM" ON PNEUMONIA.

The Health of the City.—Dr. THOMAS DARTINGTON, commissioner of health of New York city, in this paper, spoke upon the Pneumonia Commission, saying that it would conduct its investigation along two main lines—clinical and bacteriological—and that information was especially desired on the following points: 1. The occurrence and virulence of the pneumococcus and organisms related to or resembling it in the human mouth in health and disease. 2. The evidence and the extent of variations in virulence of the pneumococcus under different conditions. 3. The occurrence of the pneumococcus in children's hospitals, homes, and asylums, and the bacteriology of the mouth before and after outbreaks of pneumonia. 4. The vitality of the pneumococcus under various conditions. 5. The value of mouth disinfection. 6. The bacteriology of the air of public places, conveyances, and buildings and private dwellings, especially in reference to the amount of dust, the public buildings to embrace stores, factories, large office buildings, public schools, theatres, and hospitals. 7. The clinical evidence of the communicability of pneumonia as shown by the collection of cases in private houses and public institutions. 8. The seasonal relations of pneumonia. 9. The collection of statistics of pneumonia of the different varieties occurring in hospitals, special attention being paid to terminal pneumonia. 10. The collection of evidence as to the proportion of cases in which pneumonia could be regarded as an autoinfection and the proportion of cases in which there was evidence of the communicability of the infectious agent. 11. The study of sporadic cases of pneumonia, special attention being given to relationships of the individual to crowds or to exposure to other cases of pneumonia, and the determination of the presence of the pneumococcus in the mouth in those cases and cases associated with them. 12. The evidence for the belief that pneumonia was infrequent in Arctic regions. 13. A statistical study of pneumonia, covering its prevalence in different latitudes and in different countries and cities, its yearly and seasonal variations, and its types and mortality.

The Symptomatology and Diagnosis of Atypical Forms of Pneumonia.—Dr. J. C. WILSON read this paper (see page 788).

The Medical Treatment of Pneumonia.—Dr. H. A. HARE, in a paper with this title, dealt chiefly with the point that the statistics as to the mortality and as to the results of treatment in pneumonia were practically valueless, because different types of this disease were considered under the one heading of pneumonia, when in reality only the most careful distinction of different types

could give reliable statistics. Again, much depended upon the age of the patient and the time at which treatment was instituted. He approved of the use of moderate doses of digitalis and belladonna for a failing circulation and advised a more moderate employment of strychnine and the rare employment of nitroglycerin, except in cases of definite indication for its use. The subjects of venesection, hypodermoclysis, and intravenous injection were also considered.

Some Recent Developments in the Ætiology and Pathology of Pneumonia.—Dr. WARFIELD T. LONGCORE, in this paper, said that, in spite of the extensive investigations upon the pathogenesis of lobar pneumonia, bacteriologists and pathologists had added little which aided in the diagnosis, treatment, or prevention of the disease. The exciting cause was now known to be the pneumococcus, or *Micrococcus lanceolatus*, and the organism was recognized as an inhabitant of the mouth of many normal individuals, where it led a saprophytic existence. Until recently observers had not been able to produce lobar pneumonia experimentally in animals, but within the last year Wadsworth had succeeded in producing the typical disease in rabbits by intratracheal injections of virulent pneumococci in animals which had previously been partially immunized. It was now generally conceded that in the vast majority of cases of pneumonia, if not all, the pneumococci gained entrance into the blood and set up a general infection. Tizzoni and Pacucci had recently shown that pneumococci might circulate in the blood of immunized rabbits for weeks or months without perceptible harm to the animals. Resolution had been shown by Flexner to occur by autolysis of the exudate. Antipneumococcic serum, according to Rimpan and Neufeld, contained a substance which prepared pneumococci for phagocytosis.

The Surgical Complications of Pneumonia.—Dr. JOHN H. GIBBON said that, of the surgical complications of pneumonia, empyema was the most common, and that the success of surgical treatment depended largely upon early recognition. Confirmation of the diagnosis is made with the exploring needle, which procedure should be carried out with as much care as any surgical opening of a clean, healthy cavity. When pus is present, the procedure must be followed by thorough drainage. Dr. Gibbon used chloride of ethyl as an anæsthetic, either alone or as a precursor of ether. In practically every patient beyond the age of twenty, he would do a subperiosteal resection of the rib rather than simple drainage. Masses of lymph were removed by the fingers. There should be two drainage tubes as large as the finger, and they should be stitched in. The keynote of the treatment of empyema was early and thorough evacuation of the pus, with the opening made as low in the pleural cavity as possible.

Another condition which was very common was lung abscess, due to foreign bodies lodged in the bronchi, to tuberculosis, or to pneumonia. Of the three varieties, that due to pneumonia gave the best results from surgical treatment. The diagnosis was attended with more difficulty than

that of empyema. Drainage should be carried out exactly as in empyema. In the presence of adhesions between the lung and the chest wall, one of two courses might be followed: The protection of the healthy pleural cavity by gauze packs and immediate drainage of the abscess; or stitching of the lung to the parietal pleura, allowing the formation of adhesions before drainage.

Dr. JOHN H. MUSSER referred to a few points to which his attention had been especially called in his recent observation of pneumonia; first, to the cases simulating abdominal conditions. In deciding whether the condition was one of inflammation in the upper part of the abdomen or an infection above the diaphragm, attention to a few of the classical phenomena attendant upon each condition aided in the diagnosis. Of the greater importance were the phenomena attendant upon supradiaphragmatic cases. Here the rusty expectoration or the expiratory grunt was the most valuable sign of pneumococcic infection of the lung or the pulse and respiration ratio. Examination of the blood did not aid, because in both conditions there was leucocytosis.

In distinguishing between pneumonia and meningitis, the presence or absence of the phenomena of meningitis was more helpful than that of pneumonic symptoms. The slow pulse and the rather slow respiration were among the phenomena indicative of meningeal trouble. In other instances violent hæmorrhage at the onset of the disease suggested tuberculosis. The course of the disease offered more help than the specific symptoms or laboratory signs. In still other instances delirium was so marked in the period of convalescence as to make the case atypical. This delirium, both in hospital and in private patients, came on immediately after the crisis and raged violently for from three to five days or two weeks, unattended by fever or undue change in the pulse rate. The patients recovered without any unusual cerebral complications. In none of the instances had he seen empyema follow as a complication. In one case there was abscess of the lung. It should be remembered that empyema did not always form a loculus at the base, the infection often being between the lobes.

In the treatment of pneumococcic infection it was a mistake to regard it as a self-limiting disease, believing that it would run its course and the patient recover. While this might be true, no one could tell how quickly the simplest case might become gravely toxic.

Dr. JOHN B. ROBERTS said that the surgeon came in contact with traumatic pneumonia, ether pneumonia, pneumonia due to cold from insufficient clothing (no undershirt pneumonia) in patients in hospitals, croupous pneumonia, influenza pneumonia, and septic pneumonia.

It was often difficult to determine whether a given case was one of true croupous pneumonia or of influenza pneumonia. In the incipient stage of inflammation of the lungs, which was shown by dullness on percussion, crepitant râles, and a rise in temperature, prompt and efficient dry cupping should be used. He never lost time by sending for a cupper, who would probably put on small glasses, but sent for large tumblers and put on

half a dozen of them himself, using small pieces of paper dipped in alcohol to make the vacuum in the glasses. These were left on for half an hour or more and followed usually by turpentine stupes. In sthenic cases of pneumonia, and particularly in pneumonia following gunshot or stab wounds of the lung or injury of the lung from fractured ribs, venesection was often of great value. He was confident that he had prevented congestion of the lung becoming pneumonia by efficient dry cupping, and also that he had prevented disastrous results from acute pneumonia following injuries of the lung by phlebotomy. In cases with a great deal of mucus in the bronchial tubes, he had seen life apparently saved by inverting the patient in order that gravity might act as a mechanical expectorant. The serous effusion in the pleura which occurred as a complication of pneumonia should be treated by prompt tapping. This might be done as well with the ordinary hydrocele trocar properly sterilized as with the complicated apparatus known as an aspirator.

In empyema it is necessary to evacuate the pus and lymph masses promptly. This was easily done by putting the patient in the semirecumbent posture, freezing the skin with ice and salt, and making a two and a half inch incision with a straight bistoury. It was never necessary to resect a rib in order to get room for evacuation and drainage; and he believed it better not to take the time for resection of the rib when the patient was in the serious condition for which the operation was done. If it was found, after the lapse of some weeks, that the lung did not expand and the chest wall did not sink in to close the cavity, resection might be done with much greater safety to the patient than at the time of the original incision. Many patients would never need the rib resected, and even in young children, not over a year old, he had found it easy to get a finger between the ribs and to insert a drainage tube. The incision should be made with a quick thrust of the knife, just as one would open an abscess elsewhere. The wound should then be expanded with two fingers to allow the pus to flow and the masses of lymph to escape. The latter might need to be hooked out with the finger tip. Two rubber drainage tubes placed side by side should be inserted and stitched to the skin to keep them from falling out of the wound, and should each have a safety pin in the outer end to avoid their being sucked into the chest if the suture threads should cut through the skin unobserved by the physician.

Abscess of the lung should be treated in a similar way, by free incision and boring between the ribs with the finger to evacuate the pus. No resection of a rib is needed here. Irrigation was not needed in cases of empyema, unless the temperature should show that the cavity had become septic from putrefactive germs. Then it should be washed out once or twice a day with a weak antiseptic solution or with sterile salt solution. The temperature curve indicated when the intervals between the irrigations might be lengthened.

Dr. JAMES TYSON said that no disease was more treacherous than pneumonia. There was no single treatment which might be said to be in any way curative, although there were measures

which cooperated with whatever tendency Nature had in the way of self-immunization or in the way of elimination. He did not believe, however, that treatment was without effect and to be ignored. He emphasized the early and prompt use of dry cups after the manner described by Dr. Roberts, repeated for a number of days. Certain cases were favorably influenced by the application of the ice bag over the inflamed lung. Where this method had seemed to be lacking in efficiency, he thought it due to the imperfect method of application. He was inclined to think that the best application of cold was by cloths wrung out of ice cold water and kept in place until they became warm. That the ice cloths induced deep inspiration was an added advantage. They also reduced temperature. When the temperature dropped to 100°, he had the ice cloths removed, to be reapplied if the temperature went above this point. He had found good results follow the use of creosotal in ten minim doses every four hours. He believed the diagnosis of abscess of the lung to be more difficult than Dr. Gibbon found it. Cases of pneumonia associated with delirium were less apt to be fatal, although one would naturally think that delirium was an index to the severity of the toxine.

Dr. JUDSON DALAND mentioned dilatation of the right ventricle as an important complication of croupous pneumonia. The use of venesection he found of special importance. In no condition of the blood with which he was familiar was its coagulability greater than in certain cases of croupous pneumonia. In this class of cases the use of alkaline water in large amounts, to reduce the acidity of the urine, was important. Certain cardiac stimulants were also valuable.

Dr. FRANK WOODBURY asked that the president speak upon the mode of entrance of the pneumococcus. He thought that possibly the upper air tract was occasionally a portal of entrance for the pneumococcus, though occasionally its entrance was through the bronchial mucous membrane. He suggested the possibility that abnormal conditions of the nasal mucosa might afford entrance for the pneumococcus, and that its entrance into the blood from the upper air passages might give some of the atypical forms referred to by Dr. Wilson.

The PRESIDENT spoke especially with reference to the treatment of pneumonia, believing that attention should be directed to the limitation of the area of consolidation, to the assistance of Nature in the elimination of toxins, and to the meeting of indications as they arose. He agreed with Dr. Musser that water was given too sparingly to pneumonia patients and not systematically enough. He emphasized especially the support and maintenance of the heart's action. An important question was that of just when to aid the heart and with what agents; whether to wait until the pulse tension began to fall off and the first sound of the heart became weak, or to give this aid before that period arrived. In Dr. Anders's experience, after an attack of heart failure in pneumonia toxæmia increased and death almost invariably was the result. On the other hand, when he had given cardiac tonics and stimulants suffi-

ciently early, failure of the circulation had been warded off. Strychnine he had found to be the best agent for this purpose. Nitroglycerin was another valuable remedy. He believed that the pneumococcus often made its entrance through the upper air passages.

Dr. GITHENS referred to his experimental work in the injection of adrenalin chloride into animals. The chloride caused punctate hemorrhages throughout the lungs, and if the dose was too large, in a rabbit, death was caused promptly by pulmonary oedema. A similar effect might account for some of the bad results found in pneumonia.

Dr. DARLINGTON emphasized the value of the drinking of water in pneumonia. He had lobar pneumonia himself ten years ago, with six others, all of whom died. The other men had been accustomed to a different kind of drink, and it was impossible to get water into them. Dr. Darlington had taken water in great quantities in the course of the disease, and considered himself a monument to the value of the drinking of water in pneumonia. Quinine he gave in large doses, and the result of the remedy, in his opinion, depended upon the particular epidemic. Last year pneumonia had been very fatal; this year the mortality was less. In reference to heart stimulants, if the heart began to fail, it would go on to failure irrespective of the giving of a stimulant.

Book Notices.

The Surgery of the Diseases of the Appendix Vermiformis and their Complications. By WILLIAM HENRY BATTLE, F. R. C. S., Surgeon to St. Thomas's Hospital, etc., and EDRED M. CORNER, M. B., B. C., F. R. C. S., Surgeon in Charge of Out Patients to St. Thomas's Hospital, etc. Chicago: W. T. Keener & Co., 1905. Pp. 208. (Price, \$2.50.)

The authors state that they have tried to summarize, as briefly as the importance of the subject permits, the views held by the physician and pathologist in regard to diseases of the appendix vermiformis, and they have sought to present to the profession the surgeon's view in such a way that it shall be of practical value.

A well arranged chapter on anatomy is followed by a less satisfactory chapter on pathology. In the treatment of appendicitis, while the authors do not urge immediate and therefore clinically indiscriminate operations, as the diagnosis will be in some instances uncertain, they do urge that the decision for surgical procedure should be formed, whenever possible, within forty-eight hours of the onset. It is conceded that this is difficult, and it seems strange that they find it necessary to recommend that frequent examinations in these grave abdominal lesions must be insisted on.

The incision they employ is over the inner side of the outer border of the right rectus, parallel to that muscle, which is temporarily displaced inward. The posterior layer of the sheath is then incised, the fascia cut through, and the peritoneal cavity exposed. After freeing the appendix, a clamp is ap-

plied at its base at the junction with the cæcum; it is thought that this divides the mucous membrane and the muscular coats and leaves the peritoneal surfaces in opposition, the orifice of the cæcum being plugged by the ruptured coats. The appendix is ligated and cut away; and the stump is sewed into the cæcum. This method of operation does not seem to possess advantages over those in use in this country.

There is an interesting chapter on intussusception, sarcoma, carcinoma, actinomycosis, and tuberculous disease of the organ, and there are two chapters on the complications of appendicular inflammation.

Practical Dietetics. By A. L. BENEDICT, A. M., M. D., Councillor, American Gastroenterological Association, etc. Chicago: G. P. Engelhard & Co., 1904. Pp. 383. (Price, \$1.50.)

The author reviews briefly the compositions of the human body in chemical elements, the arrangement of the latter in proximate principles, their elimination and absorption, and the characteristics of the several classes of foods. The chapter on food requirements was written before the publication of Professor Chittenden's important investigations, which showed that much less proteid was essential to health than had been supposed. The food value of different comestibles is described, and the conditions of diet and digestion are summarized. There are chapters on the dietetics of the period of growth, on organotherapy, and on the diet in various diseases.

Miscellany.

The Intravenous Injection of Diphtheria Antitoxine.—Nearly two years ago, says the *Therapeutic Gazette*, for April 15, 1905, we called attention to the suggestion of Dr. Cairns in the *Lancet*, that diphtheria antitoxine should be administered intravenously in those cases in which there was evidence of profound infection. It will be remembered that Cairns reported fifty cases of diphtheria, twenty of which were treated in this manner, with three deaths. In the *Lancet* of December 24, 1904, we note with interest a report made by Dr. Biernacki, of Glasgow, and Dr. Muir, in which they detail their experiences with the method suggested by Cairns. They seem to be doubtful as to the advantage of this method of treatment over the ordinary subcutaneous injection, and yet, on the other hand, they tell us that there was a mortality of only three in thirty-eight severe selected cases. The fact, however, that there was a diminution in the mortality of cases of diphtheria under their care within the last few months prevents them from believing that all of this good result was due to the method which they employed.

Dr. Osler at the Annual Dinner of the McGill Medical College.—At this dinner, held on April 14th, the newly appointed Regius Professor at Oxford said:

"Mr. Chairman and Fellow Students: I taught pretty nearly everything here once except anatomy and obstetrics, and I still look back on the

period as one of the most delightful of my life. The quotation with which the chairman opened his remarks calls to my mind the great names of some of the great men whom you have here enrolled upon the lists of your professors. I am sorry that the younger of you here did not have the privilege of knowing some of the men with whom I came into contact as a student. To know George W. Campbell was in itself an education in all that was best and noblest in the medical career. Honorable, upright, and loyal, he made an ideal professor of surgery, and a splendid teacher in every way. And what impressed me most about the other men of the faculty at that time was the regularity, the punctuality, and the diligence with which every one of them, many of them in active practice though they were, attended to their duties in the medical faculty. It never surprised me that McGill grew as it has done, for these men were doing the work that they had to do, doing it thoroughly and self-denyingly, and thereby making plain to everybody what was needed to be done for the advancement of the science of medicine in this Province.

"And now that I return to the scenes of my early labors, nothing impresses me more than the great changes that have taken place in the twenty years since I left Montreal. You have two of the very best equipped hospitals on this continent (loud applause). I name those first because I believe these are the very features in which most faculties of medicine in this country are defective. Most of them are striving their hardest to secure even at great cost what this university possesses without paying a cent for. To-day I have seen two other indications of the greatest value as showing the growth of the medical school proper in this university. I went into the library this morning and there I saw fifteen or twenty students at work. There is no better indication of a healthy progress in a medical faculty than a library that is accessible to the students at all hours, and is used by them as it should be used. The second thing indicative of progress that I saw was in the museum. As I take a personal interest in the museum, and was looking around after the specimens that my friends had contributed, I saw there many students taking advantage of the facilities it offered for study. Now when you want to find out the standing and value of a medical school, always go to the museum. The museum will tell you better than anything else the status of that school.

"I will not speak of the growth of your laboratories, of the expansion of the scientific work of McGill University. Medical education is a totally different matter now from what it was in the days when I was at McGill. Medical education is a costly thing, now that you have and are obliged to have a large staff of paid assistants—not paid much, it may be, but still they get something, and it comes out of the university chest—and an immense and expensive system of apparatus, and the great difficulty all medical schools of to-day have to face is that of the pocket, and I would impress upon you that you cannot have a great medical school without full and free endowment by the citizens. You cannot have a great and growing

medical school unless the scientific departments of the university are well and fully endowed. When we think what the physiological laboratory was just twenty years ago it passes comprehension that so much has been accomplished in so short a space of time. Remember that a great medical school must be progressive, and to be progressive you must have money, and you cannot get money sufficient simply out of the fees of the students. Medical education is not much more expensive to-day in Montreal than it was when I was here, in the matter of fees at any rate, though I am told that boarding house rates are considerably higher. (Laughter.) The student does not as a matter of fact pay enough for his education. But what he does pay must be supplemented by endowments, and the point I wish to make is that these will come to you, as they have done in the past, just so long as you so richly deserve them.

"In conclusion, let me tell you briefly, how much I have been pleased at this opportunity to be present at the annual dinner of the medical faculty of McGill University, and to hear the very kind expressions that you have been good enough to voice concerning me. It gives me more courage to go across the water and enter on the duties of my new position to feel that I carry with me your kindly greetings and your good wishes for my success."

The Kansas City Medical College graduated the following young men on April 11th:

Oliver Faires, Frederick W. Tretbar, James T. Mahoney, Walter S. Hudiburg, Corydon J. Abrams, Joseph B. Blades, George T. Boyd, Roger B. Brewster, Isaac A. Campbell, L. Russell Carson, Hugh H. Cole, Laurence C. Cook, Henry C. A. Doms, Sol M. Edgerton, Albert J. Florian, Frederic E. Harvey, Claude H. Helman, William I. Huddle, Ralph W. Hull, Zachariah G. Jones, G. D. Moore Lambdin, Charles M. Miller, Fritz J. Moennighoff, Clarence A. Neighbors, James E. Ray, Wright Robertson, R. Lee Russell, James W. Sherley, C. Nelson Smith, Norris A. Smith, Eleazar M. Snodgrass, Clifton A. Thomas, F. Earl Tipton, Homer M. Walker, and Edward C. Wittwer.

The American Röntgen Ray Society.—The sixth annual meeting of this society will be held at Johns Hopkins University, Baltimore, September 28, 29, and 30, 1905. Arrangements have been made for an excellent programme, and a large attendance is expected. The papers of the meeting for the first day will deal with x ray diagnosis, and those of the second and third day will be therapeutical. There will also be an evening exhibit of lantern slides, which promises to be extremely interesting. The Belvedere Hotel has been selected as headquarters. Russell H. Boggs, M. D., secretary, Pittsburgh.

Official News.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending April 20, 1905.

BILLINGS, W. C., Passed Assistant Surgeon. To proceed to Quebec, Canada, for duty in office of United States Commissioner of Immigration.

BURKHALTER, J. T., Assistant Surgeon. Granted leave of absence for three days from April 27th.

CUMMING, H. S., Passed Assistant Surgeon. Leave of absence for ten days granted. Passed Assistant Surgeon Cumming by Bureau letter of April 10th, revoked.

FRANCIS, EDWARD, Assistant Surgeon. To proceed to Mis-soula, Mont., for special temporary duty.

GOLDSBOROUGH, B. W., Acting Assistant Surgeon. Granted leave of absence for four days from April 25th.

RICE, W. E., Acting Assistant Surgeon. Granted leave of absence for fourteen days from May 1st.

SAWTELLE, H. W., Surgeon. To report at Washington, D. C., for special temporary duty.

SMITH, F. C., Assistant Surgeon. Granted leave of absence for seven days from April 22, 1905, under paragraph 191 of the regulations.

TRASK, J. W., Assistant Surgeon. Assigned as Chief of Miscellaneous Division in the Bureau, Washington, D. C.

Promotion.

McKAY, MALCOLM, Pharmacist of the second class. Promoted to the grade of pharmacist of the first class, effective January 8, 1903.

Board Convened.

Board convened to meet at Port Townsend, Washington, April 27, 1905, for physical examination of an officer of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon J. K. OAKLEY, chairman. Passed Assistant Surgeon D. E. ROBINSON, recorder.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending April 20, 1905:

Smallpox—United States.

Places.	Date.	Cases.	Deaths.
California—Los Angeles.....	Apr. 8-25.....	3	
Dist. of Columbia—Washington.....	Apr. 15-22.....	2	1

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending April 29, 1905:

BELL, W. L., Passed Assistant Surgeon. Ordered to the Naval Hospital, Mare Island, Cal., for treatment.

DESSEZ, P. T., Assistant Surgeon. When discharged from treatment at the Naval Hospital, Norfolk, Va., granted sick leave for two months.

FURLONG, F. M., Passed Assistant Surgeon. Detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to report to the Surgeon General for a course of instruction at the Naval Museum of Hygiene and Medical School, Washington, D. C.

GARTON, W. M., Passed Assistant Surgeon. Ordered to Washington, D. C., to report to the Surgeon General for a course of instruction at the Naval Museum of Hygiene and Medical School.

MANCHESTER, J. D., Assistant Surgeon. Detached from the *Petrel* when put out of commission, and ordered to the Princeton.

REYNOLDS, C. F., Pharmacist. Detached from the *Hancock* and ordered to the Navy Yard, Mare Island, Cal., for duty in the Medicine and Surgery storehouse of that yard.

URIE, J. F., Surgeon. Ordered to the *Pennsylvania*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Corps of the United States Army for the week ending April 29, 1905:

BROWN, HENRY L., First Lieutenant and Assistant Surgeon. Ordered to accompany First Squadron, Seventh Cavalry, from Fort Myer, Va., to Manila, P. I., for duty, instead of Ninth Infantry, from Madison Barracks, N. Y. Granted sick leave of absence for fourteen days.

BUSHNELL, GEORGE E., First Lieutenant and Assistant Surgeon. Detailed to represent the Medical Department of the United States Army at the meeting of the National Association for the Study and Prevention of Tuberculosis, to be held in Washington, D. C., May 18 and 19, 1905.

CHIDESTER, WALTER C., First Lieutenant and Assistant Surgeon. Granted two months' leave of absence.

CLAYTON, JERE B., Captain and Assistant Surgeon. Relieved from duty at Fort W. H. Seward, Alaska, and ordered to proceed to Seattle, Wash., and report by telegraph to the Military Secretary for further orders.

CRAIG, CHARLES F., First Lieutenant and Assistant Surgeon. Relieved from duty at the United States Army General Hospital, Presidio of San Francisco, Cal., and assigned to duty as surgeon on the transport *Logan*, on arriving in Manila, to report for duty in the Division of the Philippines.

EBERT, RUDOLPH D., First Lieutenant and Assistant Surgeon. Ordered to make inspection of the medical de-

partment at Forts Walla Walla, Wright, Worden, Casey, Flagler, Lawton, Ward, and Columbia, Wash., and Fort Stevens, Oregon.

EDWARDS, JAMES F., First Lieutenant and Assistant Surgeon. Granted two months' leave of absence.

HUTTON, PAUL C., First Lieutenant and Assistant Surgeon. Left General Hospital, Fort Bayard, New Mexico, on ten days' leave of absence. Leave of absence extended thirty days.

PALMER, FRED W., First Lieutenant and Assistant Surgeon. Reports for duty at the United States Rifle Range, Arcadia, Mo.

REYNOLDS, F. P., Captain and Assistant Surgeon. Relieved from duty at the Presidio of San Francisco, Cal., and ordered to Fort W. H. Seward, Alaska, for duty.

ROBERTS, WILLIAM, First Lieutenant and Assistant Surgeon. Reports arrival at Fort Greble, R. I., for temporary duty.

ROCKHILL, E. P., First Lieutenant and Assistant Surgeon. Sick leave extended thirty days. Relieved from duty at the Presidio of San Francisco, Cal., and ordered to Fort Wingate, New Mexico, for duty.

RUSSELL, FREDERICK F., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Wingate, New Mexico, and ordered to the Presidio of San Francisco, Cal., for duty.

STRAUB, PAUL F., First Lieutenant and Assistant Surgeon. Having reported to the Secretary of War, ordered to duty with the Isthmian Canal Commission.

WADHAM, S. H., First Lieutenant and Assistant Surgeon. Relieved from duty as surgeon of the transport *Logan*, and ordered to report to the Military Secretary of the United States Army for further orders.

WEBBER, HENRY A., First Lieutenant and Assistant Surgeon. Detailed a member of the board to meet at Vancouver Barracks, Wash., to examine candidates for admission to the United States Military Academy, West Point, N. Y.

WILLIAMS, A. W., First Lieutenant and Assistant Surgeon. Assigned to temporary duty with the troops from Fort Hamilton, N. Y., to Army and Navy exercises, Fort Monroe, Va.

WILSON, JAMES S., Captain and Assistant Surgeon. Assignment to duty with the joint Army and Navy exercises, Fort Howard, Md., revoked.

YOST, JOHN D., First Lieutenant and Assistant Surgeon. Ordered to proceed from Honolulu, H. T., to the Presidio of San Francisco, Cal., for examination for advancement to rank of captain; upon completion of examination to return to Honolulu.

SPANGLER-KIEFER.—In Philadelphia, on Thursday, April 27th, Dr. Ralph Huston Spangler and Miss Marilla Kemmerer Kiefer.

STARIBD—HURST.—In Brooklyn, N. Y., on Wednesday, April 26th, Dr. Edward Perley Staribrd and Miss Eliza Hurst.

THOMAS—RHEINFRANK.—In New York, on Tuesday, April 25th, Dr. William Sturgis Thomas and Miss Emma Rheinfrank.

Died.

ALLEN.—In Haverhill, Massachusetts, on Sunday, April 23rd, Dr. Franklin H. Allen, in the fifth year of his age.

BARBER.—In Ossining, N. Y., on Monday, April 24th, Dr. Hiram Barber, in the eighty-sixth year of his age.

BROWN.—In Springfield, Massachusetts, on Saturday, April 22nd, Dr. Anthony L. Brown, in the forty-third year of his age.

CARPENTER.—In Newark, New Jersey, on Tuesday, April 18th, Dr. Charles W. Carpenter.

DE WITT.—In Oswego, N. Y., on Tuesday, April 18th, Dr. Byron De Witt, in the seventy-ninth year of his age.

EDWARDS.—In Ann Arbor, Michigan, on Wednesday, April 26th, Dr. William Edwards, of Kalamazoo, in the fifth year of his age.

GARD.—In Greenville, Ohio, on Monday, April 24th, Dr. Isaac Newton Gard.

GREENMAN.—In Troy, N. Y., on Tuesday, April 25th, Dr. C. E. Greenman.

GRIFFITH.—In Washington, D. C., on Sunday, April 23rd, Dr. Samuel H. Griffith, United States Navy.

HERTZOG.—In Pittsburgh, Pennsylvania, on Tuesday, April 18th, Dr. Charles Henry Hertzog, in the thirty-seventh year of his age.

HINTON.—In New York, on Wednesday, April 26th, Dr. John H. Hinton, in the seventy-ninth year of his age.

KAEMMERER.—In Hoboken, New Jersey, on Tuesday, April 25th, Dr. Charles Kaemmerer, in the eighty-third year of his age.

LYNCH.—In New York, on Saturday, April 22nd, Dr. Patrick J. Lynch, in the seventy-eighth year of his age.

MELLISH.—In El Paso, Texas, on Saturday, April 22nd, Dr. Ernest J. Mellish.

MOONEY.—In Standish, Michigan, on Friday, April 21st, Dr. G. Mooney.

NORDBROCK.—In Brooklyn, N. Y., on Wednesday, April 26th, Dr. Julius Adolph Nordbrock, in the thirty-eighth year of his age.

RICE.—In South Framingham, Massachusetts, on Tuesday, April 18th, Dr. George Rice, in the sixty-eighth year of his age.

SCHUYLER.—In Mecklenburg, N. Y., on Sunday, April 16th, Dr. J. E. Schuyler, in the seventy-fourth year of his age.

SHANNON.—In Elkhorn, Nebraska, on Friday, April 21st, Dr. William Cummings Shannon, United States Army, in the fifty-fourth year of his age.

SMART.—In St. Augustine, Florida, on Sunday, April 23rd, Colonel Charles Smart, assistant surgeon general of the United States Army (retired), in the sixty-fifth year of his age.

STEWART.—In Pittsburgh, Pennsylvania, on Sunday, April 9th, Dr. John Gordon Stewart, in the fifty-fifth year of his age.

TOWNSEND.—In Princess Anne, Maryland, on Saturday, April 15th, Dr. Elton W. Townsend.

ULRICH.—In Chester, Pennsylvania, on Monday, April 24th, Dr. William B. Ulrich, in the eighty-fourth year of his age.

WALKER.—In Rochester, N. Y., on Monday, April 17th, Dr. Charles E. Walker, in the fifty-first year of his age.

WEHRLI.—In Chicago, on Sunday, April 16th, Dr. Albert C. Wehrli.

WEYLAND.—In Denver, on Thursday, April 20th, Dr. I. S. Weyland, in the sixty-fourth year of his age.

WHITING.—In Telluride, Colorado, on Sunday, April 16th, Dr. Floyd A. Whiting, in the forty-sixth year of his age.

Births, Marriages, and Deaths.

Married.

ABBE—BROWN.—In Providence, Rhode Island, on Saturday, April 22nd, Dr. Truman Abbe and Mrs. Reginald C. Brown.

BARTHOLOW—BRICE.—In Philadelphia, on Tuesday, April 25th, Dr. Paul Bartholow and Miss Anna Lewis Brice.

GATES—HIGHTOWER.—In Denver, on Friday, April 21st, Mr. O. C. Gates and Dr. J. Gypsy Hightower.

MAHAFFEY—FOGG.—In Camden, New Jersey, on Wednesday, April 26th, Dr. Jesse L. Mahaffey and Miss Alice W. Fogg.

MCCONNELL—LISTER.—In Toronto, Ontario, Canada, on Wednesday, April 19th, Dr. John Herbert McConnell and Miss Frances Charlotte Lister.

MILLS—ALEXANDER.—In New York, on Wednesday, April 26th, Mr. Alexander Mills, Jr., and Miss Aimée Gabrielle Alexander, daughter of Dr. and Mrs. Welcome T. Alexander.

PARR—OLNEY.—In Spokane, Washington, on Thursday, April 20th, Dr. Howard Parr and Miss Aurora Olney.

SCHWYZER—ROBINSON.—In Minneapolis, Minnesota, on Thursday, April 20th, Dr. Gustav Schwyzzer and Mrs. Mary Robinson.

THE INFLUENCE OF COBRA VENOM ON THE PROTEID METABOLISM.*

By JAMES SCOTT, B. Sc. EDIN., M. D., C. M.,

EDINBURGH.

(From the Research Laboratory of the Royal College of Physicians, Edinburgh.)

Although so much valuable work has been done upon the physiological action of cobra venom by Fraser, Calmette, Elliot, and others,¹ so far no observations of its effects upon the metabolism have been recorded. While its peculiarly selective action on the central nervous system would seem to suggest the absence of any marked general action, the demonstration afforded by Elliot's work of its influence and the way in which peripheral nerve mechanism may be attacked, and of its interference with respiration, and the direct local action on the tissues into which it is injected, seem to indicate that its toxic action may extend to protoplasm generally and that it may thus lead to modification of the proteid metabolism, whether in the direction of altering the rate of proteid metabolism or of modifying the synthetic processes in the liver by which urea is elaborated, as do the toxins of certain microorganisms.

I have to thank Sir Thomas R. Fraser for his kindness in giving me the cobra venom; and also to thank Dr. Noël Paton for much valuable assistance in this investigation.

GENERAL PLAN OF INVESTIGATION AND METHODS.

Dogs were used for this investigation. Before each experiment they were fed for some days on a fixed diet of oatmeal porridge and milk in order to establish nitrogenous equilibrium. The urine was collected by keeping the animal in a cage with a sloping bottom made of zinc under which a suitable vessel was placed. The floor was kept scrupulously clean, and faeces were removed as soon as possible after they were passed. The urine was collected daily at 10 a. m.

When the animal came into nitrogenous equilibrium, sublethal and in some cases lethal doses of cobra venom were injected subcutaneously.

* Communicated to the Royal Society by Sir Thomas R. Fraser, F. R. S., April 6, 1905.

¹ See Fayer: *Thanatophidia of India*; Brunton and Fayer, *Roy. Soc. Proc.*, vol. 22, 1874; Wall, *Indian Snake Poisons*, 1883; Nicholson, *Ophiology*, 1893.

Urine.—The reaction and specific gravity were taken. The quantity collected was noted and the urine diluted to a convenient volume. The amounts of the following ingredients were determined by the methods enumerated, duplicate analyses were made in all cases and the means of these taken:

1. Total nitrogen by Argutinsky's modification of Kjeldahl's method.
2. Nitrogen in urea by Bohland's method by precipitating with phosphotungstic (Merck's) and hydrochloric acids.
3. Nitrogen of ammonia by Schlössing's method.
4. Nitrogen not in urea (non-urea nitrogen) was calculated by difference.
5. Nitrogen in purin bodies by Krüger and Wulff's method.²
6. Phosphoric acid as P_2O_5 by titrating with uranium nitrate.
7. The percentages of nitrogen in urea, not in urea (non-urea nitrogen), in ammonia, in purin bodies, in other compounds were calculated in terms of total nitrogen.
8. The percentages of P_2O_5 were calculated in terms of total nitrogen.

Averages of the figures before and after the injections were determined.

Albumin was tested for by cold nitric acid and by heat and acetic acid.

Some of the experiments were rendered valueless by the early development of an abscess at the seat of inoculation, but the following were carried on, without disturbance from such accidents.

In all the experiments no marked symptoms were produced. In some cases after injection the dog lay very quiet for a few hours. In a few there was a local swelling observed next day, but it soon disappeared.

EXPERIMENT I.

For this experiment a retriever weighing 18 kilogrammes was used. The dog was kept in its cage for two or three days before the examination of the urine was begun, so that it might get accustomed to its diet and nitrogenous equilibrium be established.

FOOD ANALYSES.

Analyses of the food given to the dog showed the amount of nitrogen to be:

Daily diet: 500 c. c. milk.....= 1.83 grammes nitrogen.
200 grammes oatmeal.....= 4.30 grammes nitrogen.

Total intake of nitrogen per dlem.= 6.13 grammes nitrogen.

Analyses of the urine were begun on November

In no case was there any indication of an increased proteid metabolism.

ber 16, 1903, and on the 19th, at 4 p. m., 1.25 milligrammes cobra venom dissolved in 0.5 c.c. sterilized normal saline solution was injected subcutaneously in the side.

The minimum lethal dose of the venom as determined is 0.00025 gramme per kilogramme of body weight. Aseptic precautions were used. The effects of this injection were studied for five days and a second injection of 2.5 milligrammes cobra venom dissolved in 1 c.c. saline solution was injected on the 25th at 9.30 a. m., and the examination of the urine carried on till November 30th.

EXPERIMENT 2.

For this experiment a collie, weighing 17 kilogrammes, was used. The same precautions were taken and the same amount of food given.

The analyses of the urine were begun on March 22, 1904, and on the 26th 5 milligrammes cobra venom in 0.5 c.c. sterilized normal saline solution was injected subcutaneously in the side at 11 a. m. A few hours after the injection, the dog vomited, but there was no other symptom. The effects of the venom were studied till the 30th.

EXPERIMENT 3.

The same collie was used for this experiment. On April 8th, at 1 p. m., 20 milligrammes cobra venom in 2 c.c. sterilized normal saline solution was injected subcutaneously. This amount is equivalent to two minimum lethal doses. No urine was passed on the 8th. The urine of the 9th, 10th, and 11th was examined. On the 11th an abscess was observed below the seat of inoculation and the animal was destroyed by chloroform.

EXPERIMENT 4.

For this experiment a retriever, weighing 12 kilogrammes, was used. The analyses were begun on June 30th and were continued till July 12th. On the 6th, 7th, and 8th of July 3.3 milligrammes cobra venom was injected subcutaneously each day at 3 p. m.

Distribution of Nitrogen in Urea and Other Compounds:

PERCENTAGES OF UREA NITROGEN TO TOTAL NITROGEN.

	Experiments			
	I.	II.	III.	IV.
Averages before injection.....	80	84	84	84
Averages after first injection....	80	81
Averages after second injection... 78	85	..
After three injections.....	77

In three of the experiments there was a slight fall in the production of urea nitrogen, most marked in Experiment IV, where three doses in succession had been given.

PERCENTAGES OF AMMONIA NITROGEN TO TOTAL NITROGEN.

	Experiments			
	I.	II.	III.	IV.
Averages before injection.....	5.57	6.4	6.4	8.9
Averages after first injection....	7.99	6.7
Averages after second injection... 11.6	6.8	..
After three injections.....	9.8

In Experiment I there was a marked rise and in Experiment IV a slight rise, while the changes in the other two was in the same direction.

PERCENTAGES OF NITROGEN IN PURIN BODIES TO TOTAL NITROGEN.

Averages before injection.....	0.85	1.12	1.12	1.35
Averages after first injection....	1.18	1.64
Averages after second injection... 1.16	1.49	..
After three injections.....	1.56

These changes show a slight rise in each experiment.

PERCENTAGES OF NITROGEN IN OTHER COMPOUNDS TO TOTAL NITROGEN.

	Experiments			
	I.	II.	III.	IV.
Averages before injection.....	13.91	8.11	8.11	5.8
Averages after first injection....	10.58	11.18
Averages after second injection... 8.89	6.35	..
After three injections.....	11.78

In two experiments there was a rise and in two a fall.

PERCENTAGES OF P_2O_5 TO TOTAL NITROGEN.

	Experiments			
	I.	II.	III.	IV.
Averages before injection.....	23	31	31	38
Averages after first injection....	29	31
Averages after second injection... 28	23	..
After three injections.....	42

In two experiments a rise, in one no change, and in one a fall. The variations in the P_2O_5 do not correspond to the changes in the purin bodies.

CONCLUSIONS.

1. Practically no change in rate of proteid metabolism was induced by the administration, in spite of well marked local reaction.
2. A slight decrease in the proportion of urea nitrogen, quite insignificant compared with that produced by diphtheria toxine, and various drugs was observed.
3. A slight rise in the proportion of ammonia nitrogen occurred.
4. There was a slight rise in the proportion of nitrogen in purin bodies.
5. The nitrogen in other compounds showed no constant change.
6. The P_2O_5 excreted showed no constant change, but in two experiments there was a slight rise.

The change produced in the proteid metabolism is, therefore, small, and such as it is, being in the directions of decreased elaboration of urea and increase in the proportion of nitrogen excreted as ammonia, it seems to indicate a slight toxic action on the hepatic metabolism rather than a general action on the proteid changes; and tends to confirm the view that the poison acts chiefly upon the nervous system.

Huron Street Hospital, Cincinnati.—The following young women have received nurses' diplomas from the training school attached to this hospital:

SOME OF THE PRINCIPLES OF MANUAL THERAPY. ITS APPLICATION BY THE PHYSICIAN.*

By JOHN P. ARNOLD, M. D.,

PHILADELPHIA.

I cannot hope to give you more than a few ideas of the principles involved in the practice of manual therapy, but I shall try to arouse your interest sufficiently to induce you to make some observations for yourselves. I do not ask you to accept the "hall marks" that I may have stamped on the subject personally, but ask you to investigate for yourselves and draw your conclusions from the evidence you obtain.

We have advanced in bacteriology, pathology, hygiene, and the general study of medicine, but we are not much better equipped than our forefathers were in treating a large proportion of cases, especially those of chronic disease. There are several reasons for this. One is the difficulty in ascertaining the exact value of the ordinary therapeutic measures, especially of drugs. So long as we are not in a position to determine the effect of the remedies that we put into the system, and so long as we cannot localize their effects, we are still in the position of our predecessors in that we have to prescribe our medicines very largely upon an empirical basis.

The chemist well knows the fact that if he wishes to determine the result of mixing two chemicals, he must know the composition of both. The composition of *living* protoplasm is to-day just about as unfamiliar to us as it was fifty years ago, and it is probably impossible for us to determine the composition of *living* protoplasm, for the moment the chemist attempts to analyze it the protoplasm is killed. While we know the composition of dead protoplasm we have no idea of the changes that take place in passing from life to death. As the effect of drugs in the main is a chemical reaction upon protoplasm, we are not in a position to determine the effects we are going to produce upon the body, and we have very largely to determine our results and regulate our practice by empirical prescribing.

If we are treating a case of sciatica by drugs we put something into the stomach that goes throughout the organism, and no matter what good results we may obtain, we have no idea of the damage that may be done to other cells. We realize the fact that the proper and judicious prescribing of drugs may help patients get well, but there are some other therapeutic measures that we have neglected. For instance, I may cite the

use of heat and cold. We all know that valuable results are obtained by the application of the hot water bag and the ice bag, yet we prescribe these things with very little or no knowledge of their physiological action, and often use heat when cold would be better and vice versa.

There is no doubt, not only from my own experience and that of others, but from abundant literature, that we have a valuable therapeutic measure in manual therapy. I do not for a moment want you to feel that I advocate manual treatment as a "cure all." We get out of college with several erroneous ideas in regard to practical work. In the first place we somehow or other feel that it is rather beneath our dignity to place our hands on our patients for the purpose of treatment. This is a mistaken idea. There are many things we have to do to help our patients get well that may seem beneath the dignity of the physician, but so long as they are a part of the physician's work, they are well worth doing. I think that this has been one of the things that has prevented the physician from studying and using manual therapy. Another reason has been the prevailing idea that muscular force and a great deal of time was necessary in applying manual treatment. This is entirely erroneous.

The results of manual treatment are recognized. We know very well that massage, Swedish movements, and exercise produce serviceable results in the treatment of disease. We know that very often when we cannot cure a patient by the ordinary methods of prescribing we send the patient to a masseur and the patient gets well. Naturally, with the egotism that belongs to most individuals, we take the credit of curing the patient, though the masseur should have some of it. If patients get well by this method, applied in this crude form, by comparatively uneducated individuals; if they get patients well when we fail, it seems to me that it should be forced upon us that here is a therapeutic measure capable of much good, and the question should naturally arise, Is there not a larger field and is there not something that we might do better than can be done by the masseur?

Some years ago I noticed that the moment you put a muzzle, such as is commonly used in the laboratory, on a dog, no matter how violent the animal was it became quiet. In making a large number of observations upon animals under these conditions, and in studying the physiology of the results of pressure upon various parts of the body, I found that pressure upon the occipital nerves produced a certain amount of cerebral anæmia. This served to explain why the animal became

* Address delivered before the Medical Society of the Women's Medical College, Philadelphia, April 9, 1904.

quiet. You will find in patients, if you will take the trouble to make the observation, that light continued pressure over the occipital nerves produces a peculiar quiet, and they often say they feel as if they would like to go to sleep. If we carry out these observations a little more systematically we find that pressure along the spinal column and in certain regions of the neck does produce distinct changes in the circulation in the central nervous system. This is well recognized empirically, but we have not had heretofore the knowledge which would enable us to apply it with that certainty and system which would give us the ability to localize the effects in certain regions. I must say that the experimental evidence of this is for several reasons rather unsatisfactory to demonstrate to those untrained in physiological work. One of these is that the spinal cord is very richly supplied with blood, and experimental work upon the cord is unsatisfactory to the general observer, because the amount of hæmorrhage is such that the results are very much obscured.

The study of the development of the organism and the fundamental laws which determine the activity of every living organism teaches us that there are principles which serve to explain the results that can be obtained by pressure along the spine. The body is developed practically as two double tubes, one, the anterior body tube which consists of the trunk and contains the primitive intestinal tube; posteriorly, that region supplied by the posterior primary divisions of the spinal nerves, consisting of the muscles of the back in a region about three inches on each side of the spinal vertebræ, the vertebræ, and the ligaments makes up the outer tube and this contains the neural tube. We have long recognized the fact that the circulation in the anterior body tube, or the muscles and skin of the trunk, was in a measure compensatory to the circulation of the organs within (developed from) the inner tube; e. g., the application of a mustard plaster over a pleurisy or a congested liver is of service in relieving the congestion. We have never applied the same principles to the circulation in the skin and muscles of the back as compensatory to the circulation in the spinal cord. This thought occurred to me in working on this subject, and I might say that that is one of the fundamental principles of the application of manual treatment. I have seen so many times agents that produce a dilatation of the blood vessels in the skin and muscles of the back relieve congestion of the spinal cord that I came to the conclusion, I might say empirically, that there must be some sort of a compensatory relationship between the circulation in the two

parts. That these results were produced has frequently presented itself to me as evidence in practical work, and to make the matter more clear I carried out a series of experiments some eight years ago which shows very distinctly that pressure along the back does modify the circulation in the cord.

We find that internal conditions, no matter what they may be, manifest themselves by certain distinct signs that may be observed by the proper examination of the back. For instance, I have not seen any case of dyspepsia, no matter of what type, in which there was not distinct evidences in the mid-dorsal region of a disturbance of the nervous mechanism controlling the stomach, and here we have to realize that fact that we have not only a nervous mechanism to the blood vessels of the stomach, but one controlling in part the musculature of the walls of the stomach itself. If we examine a case of asthma we will find the disturbance in the upper dorsal region between the third and the seventh, and so on throughout the whole list of diseases.

With a subject so broad as that of therapy I cannot hope, in this brief talk, to give you any more than a faint idea of what we may be able to determine and what we may be able to do, but there is one thing I do hope to do and that is to arouse your interest sufficiently to have you make observations yourselves, and I am quite sure if I can do that I will need say little more, because the evidence is so plain that you will have no difficulty in corroborating what I tell you.

In recent years we have placed too much dependence upon laboratory methods—blood examination, analysis of gastric contents, analysis of urine, and so on—to the exclusion of some of the things that our predecessors in medicine knew very well. We have, in consequence, largely lost the art of careful observation of the things we see, feel, and hear. There are no things that are too trifling or of too little consequence to be carefully observed and carefully analyzed in examining the sick. We must recultivate our ability to observe carefully.

If you will take the trouble to examine the backs of your patients you will find that you will get data of value not only as to the conditions that exist, but also data which will be extremely serviceable to you in curing your patients. If a person starts in prejudiced, with the idea of finding certain things that he is looking for, the chances are that his judgment will be so biased that he will find them whether they exist or not. I have made it a rule to examine the patient first and listen to his story afterward so that my conclu-

sions will not be vitiated by the tale of the patient, and I believe that this is a good plan to follow. We know very well that if a patient comes into the office and tells us the history of the case with the belief that he is suffering from such and such a condition we are very apt to be swayed in our judgment and come to conclusions that are entirely unjustified by the physical signs that present themselves. Make the examination of the patient and then modify your judgment by the history. You will find that you are very much more likely to come to the correct conclusion if this plan is followed.

How can manual therapy affect the organism? If we take a few moments in consideration of some of the elementary principles of biology we realize the fact that every living organism is a mechanism which expresses its activity in response to changes in the conditions that surround it. In other words, we, as men and women, are machines that respond to changes in conditions that surround us. If an *amœba* is placed under the microscope and observed closely, it will show in a simple way all of the fundamental principles which serve to explain the activity of the higher forms of animal life. For instance it moves across the stage of the microscope. If in any way we alter the conditions surrounding the cell, as by pricking it with a pin, it will respond by actual movements. The prick of a pin will produce a contraction of the protoplasm. If a pseudopodium happens to be projecting from the opposite side from the pin prick it will immediately be withdrawn, showing that the cell possesses the power of conductivity. This mass of protoplasm responds to external irritation. It possesses one of the fundamental characteristics of living material, *irritability*. It possesses *conductivity*. It is found after a time to divide by simple cell division, and instead of one there are two. It possesses the power of *reproduction*. If the water which surrounds the *amœba* is examined we will find that oxygen is absorbed and that carbonic acid gas is given off (*respiration*). It also takes into its interior certain materials which are found in the water which surrounds it, *digests* them, *assimilates* them, and uses them for the production of energy. We will also find that the protoplasm in this little cell is in constant motion, and in very many of the *amœbæ* we find a clear space that has the property of rhythmically contracting and relaxing. This produces a certain amount of constant motion of the protoplasm. In other words, the *amœba* has a *circulatory apparatus*. This corresponds to the circulatory apparatus in the higher animals.

In man we have to deal with a social cell community made up of simple individuals which correspond to the *amœbæ*. And we should approach the study of physiology and anatomy and the study of disease from this standpoint and look upon the human being as simply a cell community made up of a large number of simple organisms, realizing that these simple cells are governed by the same laws and principles, modified, but not altered, because in the social organization of the cells they have undergone certain changes in form and specialization of function.

In the development of the organism of the higher animals, just as there is in the development of every social organization, certain individuals in the organism develop peculiarities which fit them best for the work they have to do, and very often they lose some of the primitive attributes. In the organization of the higher forms of animal life a certain group of cells became specialized in two of the characteristics of the simple cells, and these are irritability and conductivity. Irritability is the capacity to respond to changes in environment, and conductivity is the ability to conduct the results of changes in environment to different parts of the organism. Thus in the higher forms of animal life is developed a group of cells which make up the central nervous system. The community of cells which make up our bodies becomes so complex from the number of individuals present that it becomes necessary for some governing mechanism to be developed in order to control the activity of the various cells and prevent damage from occurring in distant parts of the organism. The nervous system is that part of the organism which responds most readily to changes in external conditions and which enables us to adapt ourselves to the conditions which surround us. We all realize the fact that if we go into a cold region we preserve our body temperature within very narrow limits, and the same is true if we are exposed to excessive heat. This is brought about by the regulation of the calibre of the blood vessels and the production and distribution of heat. This is accomplished by the central nervous system. This being the fact brings this point to mind; may we not so systematically change the environment of the body that we may in a measure modify not only the normal conditions of the body, but also be able to govern pathological conditions? That we may is borne out by clinical, embryological, and physiological evidence.

Physiologists have for years recognized that the vasomotor system consisted of certain cells, located in the spinal cord and in the medulla,

which send impulses to the muscular walls of the blood vessels, and also of sensory nerves which transmit messages from different parts of the body to the central nervous system. They have also recognized the fact that certain kinds of stimulation, or, I might say, changes in external conditions, bring about dilatation of the blood vessels, and certain others, contraction. For instance physiologists have recognized that the rapidly interrupted electrical current produces contraction of the blood vessels in the part supplied. If instead of the rapidly interrupted current we apply the continuous current, after a brief contraction dilatation of the vessels occurs. The same holds true of mechanical stimulation. It was with this thought in mind that I was able to explain satisfactorily that this is the result obtained in treatment by manual pressure along the spinal column. In other words, that repeated, brief pressure along the spinal column arouses the reflex constrictor nerves and brings about a certain amount of contraction in the blood vessels of the skin and muscles of the back in the region of the back treated. That this does occur can very easily be shown by very simple experiments, and it also undoubtedly produces at the same time a certain amount of dilatation of the vessels in the cord. On the other hand continuous pressure along the spine arouses the reflex dilators and brings about a certain amount of dilatation of the blood vessels in the skin and muscles of the back and a corresponding contraction of the blood vessels in the cord.

It may seem that this is a broad statement to make with very little actual evidence that could be demonstrated. However, that these results are obtained is borne out by actual experience in the treatment of patients; it is borne out by embryological evidence and experiments in physiological work. Whether this is the true explanation or not carries with it very little weight. The most important thing to bear in mind is that we get results, but one thing you can be quite sure of is that if we apply manual treatment along the spine, used with judgment which should come to us because of our education in medicine, we can do no harm, but in the hands of the ignorant much damage may be done.

Why should we neglect a valuable therapeutic measure for sentimental reasons or because we feel that we may be called masseurs? Our real object in life is to get our patients well no matter what means we use, and if we cannot do that we are not good doctors. You need not fear what the people will say about you. There has been a great deal of condemnation of manual therapy which has been the outcome of ignorance of its

real value and ignorance of the proper methods of application. In the ordinary application of manual therapy it takes no more time than it takes us to write a prescription. The idea has prevailed that it took from a half hour to an hour to treat a patient. We have had ground into us that muscle is needed, and the harder we do it the better it is for the patient. This is not true. Manual therapy is probably one of the sharpest instruments we have, and it must be applied with brains and not with muscle. A great many patients that we have to treat require no more than the pressure that would be produced by a half pound weight and less than ten minutes' time. That this does produce results is shown from day to day by the fact that patients get well, patients who have been under the ordinary therapeutical measures not only for months, but sometimes for years. As I said in the presence of some of you here, there is no reason why I should be able to do more than any of you may do. What I have done in the treatment of some cases that have been looked upon as incurable, can be done by any of you if you will take the trouble to observe your patients and apply the methods. It is not necessary for one to have brain power above the capacity of the ordinary individual or doctor, but it means that we must take the trouble to investigate and make use of all those things which are of value in the treatment of disease, and we must blame ourselves if we neglect any of those things which may help us get our patients well. If we will take the trouble to approach all of these things with an open, clear mind, with the idea of getting everything of value, and not allow our prejudices to interfere with our judgment, we shall have performed our duties to our patients and to ourselves, but if we allow our sentiments to vitiate our judgment we shall have failed in our duties as physicians.

I do not ask any one to accept manual therapy from my evidence alone. I only ask those who are interested in the matter to make the effort to determine the evidence for themselves, and I believe they will find a sufficient amount of very plain evidence that will enable them to make not only a better diagnosis, but will put them in a better position to help the patient get well. If in your practice you will take the trouble to examine the backs of the patients and discover all the physical signs you can, you will find there are lots of things of the existence of which you had no idea. A large class of patients come in with complaints of some minor trouble, such as an occasional attack of indigestion, constipation, etc., and when you examine the back in these cases you will find some fundamental disturbance of the nervous mechanism controlling the part of the organism affected. I

believe there are numbers of people who go through life constantly or periodically going to the doctor for what they consider some minor condition, who have had since childhood a disturbance of the nervous mechanism controlling the part of which they complain.

Above all, our duties as physicians are not alone those of curing patients when they get sick, but our chief duty is to prevent people from getting sick, and if you will take the trouble to examine the children that are brought to you and cure the minor disturbances, which do not always show themselves by distinct sickness, but which may determine sickness later in life, you will do much to further our progress toward that goal which is the highest duty of the profession of medicine, the prevention of disease.

110 SOUTH NINETEENTH STREET.

URETHROPLASTIC DISLOCATION.

By CARL BECK, M. D.,

NEW YORK,

PROFESSOR OF SURGERY IN THE NEW YORK POSTGRADUATE MEDICAL SCHOOL AND HOSPITAL, VISITING SURGEON TO THE ST. MARK'S HOSPITAL AND THE GERMAN POLIKLINIK.

In previous publications on this subject I have given a warning against employing my method of dislocating the urethra whenever excessive tension is required to place it in proper position. The extensibility of the urethra varies, however, with different individuals, and therefore, while in one case an extensive dislocation may prove to be a success, in another it may be a failure, although under similar anatomical conditions. These conditions, of course, can be discriminated with certainty only after the urethra has been mobilized. Thus the decision by the *fait accompli* puts a great responsibility upon the skill and instinct of the surgeon in the proper selection of cases.

Recently, in the case of a boy four years old, I could not resist the temptation to mobilize the urethra, although it represented that unfortunate type of hypospadias, the scrotal. One of the factors which encouraged me to risk the dislocation method even in this case was the instinctive impression that there was sufficient material for forward displacement. This impression was founded somewhat on the possibility of pulling the penis forward together with a rubber catheter introduced into the urethra.

I found little difficulty in dissecting the urethra as far as the *pars prætrigonalis*. In fastening the orifice at the top of the glans a moderate amount of tension was caused, which was partly overcome by supporting the urethra by relaxation sutures of fine catgut. These sutures are meant to fasten the outer

FIGS. 1, 2, and 3. Rectangular preputial flap; a, top of flap

urethral wall to the sulcus of the new canal at various points. As a rule two are sufficient, both to be applied below the glans.

As far as the creation of a normal orifice at the top of the glans was concerned, I had complete success; but considerable retraction occurred, the penis appearing short and slightly incurvated. In a similar case (see *New York Medical Journal*, Dec. 8, 1900) I had made a plastic correction by perforating the very long prepuce with a bistoury and dilating it by lateral excursions, so that the glans could be pulled through the preputial gap. Then the skin above the newly formed urethra was

FIG. 4. —Covering defect of abdominal wall by scrotal flap.

dissected backward toward the scrotum, so as to form a gaping wound surface, into which the preputial flap was inserted. Thus the flap appeared like a keystone between the lower margin of the glans and the retracted scrotal skin. After union had taken place the penis appeared to be elongated.

In this case there was an abundance of preputial tissue attached anteriorly, and for this reason I utilized the prepuce in a different manner. As indicated by Fig. 1, I formed a rectangular preputial flap, the top of which was at *a*, and turned its base (Fig. 2) so that it covered the wound surface made below the glans, for the purpose of relieving the retraction. The top of the flap (*a*) was then transferred to the opposite side (Fig. 3). While the penis appears rather small, yet the result as a whole is good, and further development promises more improvement still.

In the absence of the prepuce, portions of the scrotum can be utilized for the same purpose, as has been shown by Lauenstein and others. How well the scrotum can be used for covering large defects, caused by luetic as well as cancerous destruction, after restoring the urethra by the dislocation method, is illustrated by Figs. 8 and 9 of my publication in this *Journal* (Dec. 8, 1900). Fig. 3 (*l. c.*) illustrates the good use which can be made of the scrotum in destructive processes of this kind.

In a man of twenty years of age, whose suprapubic region was the seat of extensive luetic destruction, I mobilized a large portion of the scrotum and pulled it up far enough to cover the defect completely, fastening it there with a row of interrupted iodoform silk sutures (Fig. 4).

FIG. 5.—Relaxation suture introduced over simple suture.

FIG. 6.—Relaxation suture complete.

I may again call attention to the necessity of relaxation sutures such as I describe, whenever any amount of tension is expected, especially in plastic operations for inguinal, umbilical, or ventral hernia, after perineorrhaphy, or in ligamentopexis, etc. The safety relaxation sutures are applied laterally from the wound margin, so that there is no direct contact with the wound line. (Fig. 5.) Strong iodoform silk, armed with a needle of medium size, is introduced about one and one quarter inch, and brought out three fourths of an inch distant from the wound margin. The same procedure is repeated at the opposite side, so that the relaxation suture overlaps the sutured wound line. (Fig. 6.) When the relaxation suture is tied, any possible tension is taken away from the wound margin, and it seems to me of little importance what kind of suture material is used below. The separation of the wound margins, superficial as well as buried, is rendered impossible as long as the relaxation suture holds. As a rule one relaxation suture suffices. In the case described three were needed, as a certain amount of tension had to be overcome all along the upper wound margin. In abdominal cases I use thin catgut for the deeper layers as well as for the integument, while for the relaxation suture I use silk invariably.

As emphasized in the publication mentioned (*N. Y. Med. Jour.*, Dec. 8, 1900), the dislocation method

FIG. 7.—Epispadias.

can also be utilized in epispadias. Parham in his classical publication (*New Orleans Med. and Surg. Jour.*, Jan., 1901) describes a case in which with admirable success he combined the ingenious technics of Cantwell with the fastening of the dislocated urethra at the tip of the glans. Parham also suggested cutting off the urethra at its junction with the glans.

In such cases a scrotal flap is sometimes found useful for protecting and strengthening the suture line of the new urethral canal, just as I advised it for unfavorable cases of perineal hypospadias (see Fig. 12, *N. Y. Med. Jour.*, Dec. 8, 1900).

In a boy four years old (Fig. 7) I tried to protect

FIG. 8.—Large flap from suprapubic region.

the suture line after mobilizing the urethra and pulling it forward, by a scrotal flap. But the scrotum was so poorly developed that the transplanted flap proved to be too small and the result was imperfect.

FIG. 9.—Plaster of paris dressing with copal varnish.

The fact that the patient was extremely nervous had also contributed to the failure. A few months thereafter I made another attempt, this time trans-

FIGS. 10 AND 11.—Mobilized urethra pulled through penile tissues.

planting a larger integumental flap from the suprapubic region (Fig. 8). At the same time I surrounded the pelvis by a plaster of paris dressing painted with copal varnish. A small hole was left in front, just large enough to pass a rubber catheter through it, which was left *in situ*. This precaution was taken in order to prevent the patient from disturbing the area of operation, as he had done before. Siphon drainage was employed until

FIG. 12.—Urethral stumps in apposition.

a week after the operation, which proved to be successful this time. (Fig. 9.)

In a boy seven years old I recently pulled the mobilized urethra, after it was sutured, through the penile tissues. Then I fastened it at the top of the glans just as I do after perforating the glans in hypospadias. I approached the posterior surface of the penis as nearly as possible, avoiding any communication with the former bed of the epispadiac groove. After fastening, the penis appeared as it does after tunneling the glans for penile hypospadias, with the difference that the orifice was situated further backward (see Figs. 10 and 11). The result in this case was more satisfactory than in the former. The remaining anterior defect was filled up by a scrotal flap.

I conceived this idea of tunneling the penis as well as the glans for the purpose of urethral dislocation, when I observed a tendency to partial separation in a case of perineal hypospadias, after I had formed a new urethral canal from the hypospadiac groove.

FIG. 13.—Mucous membranes united with fine sutures.

There being abundant tissue, I felt encouraged to isolate the upper portion of the newly formed urethra, not leaving its posterior surface in connection with its penile tissue, and to pull it through the longitudinal tunnel made through the penis.

As mentioned in previous publications, the dislocation method can also be utilized in a retrograde manner and in many pathological conditions of the urethra, and also in the female.

This was recently corroborated by no less a surgeon than Koenig, who called the result he obtained in utilizing the principle of forward dislocation in a case of partial resection for carcinoma a surgical triumph. In the publication mentioned he said: "In all destructions of an ulcerative or traumatic nature my method will also come into consideration." In a case of formidable destruction of the urethra by a phagedenic chancre (*N. Y. Med. Jour.*, Dec. 8, 1900, Figs. 8 and 9), I succeeded in obtaining a perfect result. Not only was the glans ulcerated on the twenty-four year old patient, so that two glandular halves had formed, but the anterior third of the pendulous portion of the urethra was also totally destroyed. After the ulceration process was stopped under energetic local treatment, the necrotic urethral remainder was removed and the normal urethra situated behind mobilized and pulled forward. (Patient presented to the Medical Association of the Greater City of New York, October 8, 1900.)

Since that time I have had repeated opportunities to test the dislocation method in sclerotic conditions of the urethra, generally caused by gonorrhœal strictures.

Wherever there is an impassable stricture, urethral resection may come into consideration. In the presence of much fibrous periurethral induration, internal urethrotomy means a temporary relief only, while excision, followed by urethral dislocation, means a radical cure.

The technics of the operation is as follows: After the patient is brought into the lithotomy position, a medium sized metal catheter is introduced and gently pressed against the entrance of the strictured area. If firmly held by an assistant it will serve as a landmark. The indurated area is now exposed by a three inch incision made in the raphe. The tissues are divided step by step until the urethra is reached. The sclerotic area generally extends into the neighboring perineal muscles. After its length is ascertained, the urethra is grasped with toothed forceps, raised, and carefully freed from the surrounding tissues. After isolation is perfect, and not until then, the indurated portion is excised at its central as well as its peripheral end. The urethral stumps are now caught with silk ligatures so that they can be pulled forward and further mobilized until they can be placed in apposition (Fig. 12).

FIG. 14.—Gonorrheal stricture; dotted line shows extent.

If mobilization of the central end offers any technical difficulties, a large catheter is introduced and serves as a handle during dissection. After the mucous membranes of both urethral ends are united with fine catgut sutures (Fig. 13), a large rubber catheter provided with a shield (described below) is introduced and fastened at the top of the glans. A row of periurethral sutures is then added, and the skin wound is closed with interrupted silk sutures. No wound drainage is used.

In a man, thirty-five years of age, with a gonorrheal stricture twelve years old, the condition had been aggravated by repeated urethrotomies, internal as well as external, which were necessitated by urine infiltration. Although the cicatricial indurations had in fact displaced even the superficial fascia (Fig. 14), exsection could be completely done. Immediately afterward a large sound could be passed, while before it was only possible to pass the stricture by a filiform bougie, and even this was sometimes impossible.

All these urethroplastic procedures are of a more or less delicate nature, especially so in the case of children. Delicate operations require delicate instruments, and those commonly used do not, in my experience, answer this desideratum.

A thumb forceps, as generally used, may tear the thin urethral membrane of a child. The retractors

FIG. 16.
Toothed retractor.

holding the reflected skin flaps must hold the tissues without injuring them. The knives for dissecting out the urethra, as well as the bistoury used to perforate the glans, must be of a special and delicate construction.

I therefore requested the Kny-Scheerer Company to construct for urethroplastic operations a special set of instruments (Fig. 15)

containing all that are needed for that purpose, viz.: A small, short scalpel for the dissection of the urethra from its bed, a long bistoury for the perforation of the glans or the penile substance, two toothed thumb forceps, delicate blunt scissors curved on the flat for blunt dissection, a toothed retractor (Fig. 16), two specially adjustable holding forceps (Fig. 17), which may serve as retractors at the same time, two small elastic artery clamps, various round needles, a special needle holder, and a rubber catheter provided with a perforated shield.

FIG. 17.
Toothed adjustable holding forceps.

THE SKIAGRAPHY OF THE FUTURE.

By J. RUDIS-JICINSKY, A. M., M. D., M. E.,

CEDAR RAPIDS, IA.

Nearly ten years have passed since the first shadow picture, skiagraph, or radiograph was made with the aid of the marvelous Röntgen ray, and it seemed to open a path to other wonders which soon followed, and to-day we not only see, but photograph objects unseen by the unassisted eye. Like the work of some fabled device the Crookes's tube is the key that unlocks a world of wonder in medicine and surgery, the invisible in the living human body is made beautifully visible, and of practical value in diagnosis, which is not only possible, but absolutely correct. With the development of our special tube with prolongation, other tubes with all the accessories of our apparatus to-day, we are enabled to produce skiagraphs with all the detail possible, with all the perspective in the picture, depth, internal structure and substance of the bones, and a beauty which may be appreciated only by an experiment. We can photograph deeper structures in adults, such as the hip, spine, and shoulder. If we succeed in obviating the diffused rays throughout the mass of tissue which is interposed between the tube and the sensitive plate,

FIG. 15.—Set of urethroplastic instruments.

we will get not only clear pictures, with sharp contrast, but pictures altogether different from others made thus far. All of the forms of apparatus, which would obviate the diffusion, as for instance the lead box, tungstate of calcium,

FIG. 1.—Parts of the "protector."

screens alone, etc., had the disadvantages of being clumsy to handle, or imperfect in intensification. To eliminate all of these objections we have used in our laboratory for years a sort of "protector" with a funnel-shaped cylinder, and specula. I have promised to the readers of this *Journal* the description of this, my own device, and here it is.

The protector (see Fig. 1) is a home made combination of a protective screen and shield, mask,

FIG. 2.—Finding the proper position and measurement.

and a lead box, with diaphragms and a metal cylinder and specula for precluding the diffused x rays. The device may be used with great advantage in therapeutic work, in diagnosis, in fluoroscopic examination, and skiagraphy, giving most excellent results not obtainable without it. During the whole exposure of a patient we may observe the tube in action anteriorly and posteriorly, without disturbing the patient. In this way we not only protect the patient in prolonged exposures, but protect also ourselves during such operations and for the future from medicolegal complications, because there is no burn possible.

FIG. 3.—In action connected with Kienraide coil.

Any tube of a good make works with this arrangement more steadily, the spreading of the rays when the tube becomes high in vacuum is avoided, and so called concentration becomes possible, giving the illumination of the part exposed only. The illumination can be regulated at will. Note (Figs. 2 and 3) that the main opening is situated in such a manner that the best rays only may be employed.

With the help of this simple device we see the image on the fluoroscopic screen much sharper and clearer, without any special fluoroscope, the ordinary fluoroscope serving in all cases. In examining the hand, or some other thin object with a low vacuum tube, no particular difference is seen, but in viewing the hip joint with a medium high tube the difference in contrast is very marked, the diaphragms or cylinders with open-

FIG. 4.—Carpus, showing internal structure of bones, substance, etc., with all possible detail (enlarged). Kinraide coil exposure two seconds with a screen. Alternating current. Three plates exposed at once. Lead plate underneath.

ings technically perfect and accurately measured, enable us to preclude the diffused rays or screen them off, except the parallel rays, which are absolutely required to give us the desired shadow and the desired illumination of the part exposed. In skiagraphy with intensifying screens against the film of the photographic plate, and a lead plate underneath, the lead box can be dispensed with altogether, and we shall get beautiful pictures, clearer, and with more detail (Fig. 4). The whole arrangement and accessories to the protector weigh only about one pound and one ounce, and are easily portable with the tube, and in the same compartment, or the same box without other attachment.

DIRECTIONS.

1. Cover the tube with the protector containing lead foil inside, and papier mâché outside, and select the diaphragm or the opening suitable to each individual case. Secure the protector at the anode and the cathode with bands to the tube, or if the tube is of smaller size, simply lay the same into the shield, the anode disc being in the middle of the field to be illuminated, and at the usual angle found, as in Fig. 2.

2. In fluoroscopy and skiagraphy both, illuminate only the parts examined to get more contrast and sharpness in the pictures and shadows. Select the proper cylinder and observe the action of the tube anteriorly through the small window, which must be closed again in skiagraphy. To concentrate the rays use the special device in the shape of a funnel, or a metal cylinder, which may be raised or lowered around the openings, which again may be made larger or smaller according to the illumination necessary. If we wish, the action of the tube may be observed posteriorly also. The body of the protector, being of lead, has not only the screening off properties, but also discharging qualities, the spreading of the rays being impossible, and the work of the tube is

made steady. It may be moved with the tube in any desired direction, or put in any desired position with the tube on the same stand, or we may hang it with the tube over our operating table as we please and at any distance. The protector with the tube is lowered to fit over the part to be skiagraphed, and the metal cylinder is pressed down into the skin, and the picture taken through it.

3. To find out which opening shall be used in each individual case, use the fluoroscope and observe the pencil of the rays of the best order.

4. The opening rings are applied very easily, but have to fit properly and to be adjusted as near as possible to the tube, or rather to the anodal disc in the tube. In this way the diffused rays will be precluded.

5. The distance from the tube, the length of the cylinder, through which a part and the photographic plate must be exposed, to secure not only the illumination, but essential correctness and non-distortion has to be found with the help of our fluoroscope. The position of the subject has to be such that the best rays penetrate properly through and through the subject exposed, and only at the area examined. This depends alto-

gether upon the proper selection of the opening in the body of the protector. In skiagraphy, use the funnel shaped device always, with the largest or smallest opening. See that only the area within which a body of any thickness will shadow a right angled relation of the parts at a certain distance is illuminated and that the dry plate is as near as possible to the lesion sought. If the intensifying screen is used, the tungstate of calcium crystals have to lie right against the film of the dry plate in the two envelopes, or the casket, with a lead plate underneath. The intensifying screen must be of very fine grain.

WHEN AND HOW SHOULD THE TUBERCULOUS PATIENT BE TREATED?*

By F. M. POTTENGER, Ph. M., M. D.,

MONROVIA, CAL.,

MEMBER OF THE AMERICAN CLIMATOLOGICAL ASSOCIATION;
CORRESPONDING MEMBER OF THE INTERNATIONAL CENTRAL
BUREAU FOR THE PREVENTION OF CONSUMPTION, ETC.

It is the sad experience of all who treat pulmonary tuberculosis, that the great majority of individuals who seek aid are not seen until they have advanced to such a stage of the disease that recovery is beyond question. It is the experience of such institutions as Rutland, where it is understood that none but early cases need apply, that more than fifty per cent. of applicants must be rejected, and even then many unfavorable cases are taken.

There seems to be a very vague and erroneous idea on the part of both laymen and physicians as to when the individual is suffering from pulmonary tuberculosis, and also as to when he should begin to take active measures for the cure of the malady when it has been determined that the disease is present.

The patient thinks, as long as he has no pain in the chest and as long as he is not expectorating ounces of purulent sputum accompanied by a cough which annoys him day and night, that he cannot have anything the matter with his lungs, and when this stage has been reached he only begins to fear that the cough will "go to his lungs," unless something is done for it.

Pulmonary tuberculosis should be treated as early as it can be detected, and it can be detected before there is any serious damage to the lungs, before bacilli appear in the sputum. The medical profession has mastered appendicitis by early diagnosis, followed by immediate and energetic treatment. The same has been done for diphtheria. The same must be done for tuberculosis.

While from seventy-five to ninety-five per cent. of early cases of tuberculosis can be cured, not more than thirty per cent. of advanced patients can hope to have their disease arrested, and to the far advanced not even this hope can be offered.

It should be remembered that nearly every individual suffering from incipient pulmonary tuberculosis can be cured by appropriate treatment, and it must also be remembered that nearly every one from whom this is withheld passes on to the advanced stage and dies of pulmonary consumption.

While the fact that pulmonary tuberculosis is a very curable disease, the most curable of all chronic maladies, should be branded upon the minds of the medical fraternity, and while this blessed hope should be speedily made known to the world at large, it should be accompanied by an equally important truth, that the most curable stage is the early stage, before serious harm has been done to the lung and before the general vitality of the patient has been undermined.

In recent years it has been demonstrated to the profession that an early diagnosis, followed by immediate operation, will cure nearly all cases of appendicitis, and to-day professional opinion endorses this so strongly that a man almost fears to treat a case in any other manner. It now remains to demonstrate the same curability of tuberculosis. The evidence is at hand. The facts are obtainable, but they have not been impressed upon the profession.

Skillful treatment of tuberculosis in the incipient stage will show a mortality almost as low as early operative treatment of appendicitis. Even where breaking down has occurred and bacilli appear in the sputum and a large area of lung tissue is involved (usual so called first stage) most sanatoria secure happy results in at least sixty-five per cent. of cases. When we consider that the earliest cases rarely go to our institutions, we must call this an excellent showing.

While the clinical symptoms of early tuberculosis are not distinctive, and may easily be confounded with the signs of other diseases, nevertheless they are sufficient to put us on the alert. The clinical symptoms are at least sufficient in nearly every case to place tuberculosis in the list of diseases that must be excluded before a diagnosis can be reached. Here let me emphasize what I said on a former occasion: "A careful physical examination, made by one who is able to detect the delicate changes produced by the presence of early tubercles, together with painstaking observation and inquiry into clinical symptoms, will

* Read before the Pasadena branch of the Los Angeles County Medical Society, November 15, 1904.

either detect or exclude tuberculosis in the majority of cases before the advent of the open stage of the disease with its bacillus-bearing discharges."

It should be remembered as an important aid in making a diagnosis that tuberculosis is most apt to manifest itself when the individual's resisting power is below normal. After a prolonged physical overexertion, or mental strain, or when reduced by disease, tuberculosis often takes advantages of a man's weakened condition.

EARLY SYMPTOMS.

Some of the symptoms which should direct our attention to tuberculosis are:

1. A general run-down condition. The patient finds his energy is waning, notes a decrease in his powers of endurance; ordinary tasks become hard, sleep fails to bring rest, the appetite lags, a few pounds of weight may be lost. This condition, if it is presented to the physician, is too apt to be ridiculed, or to be treated by some simple tonic and assurance that nothing is the matter. In such cases tuberculosis must always be thought of.

2. There is apt to be a slight rise in temperature. This rise does not need to be great. It is usually only of a fraction of a degree and occurs most often in the afternoon. In order to detect it, a two hourly chart should be kept. Sometimes after an invasion of tubercles the disease becomes apparently quiescent and the rise in temperature subsides, but in such cases it can usually be detected by causing the individual to exert himself to the point of becoming tired. In women it will usually show at the time of the menses.

3. An increase in the pulse rate is usually noted. This irritability is especially noted in young persons, and is perhaps of toxic origin.

4. Another symptom sometimes present is a hoarseness, which is perhaps due to the irritation of the vagus.

5. The disease is frequently traced back to a cold from which the patient was very slow to recover. It is not natural for a simple cold to last three or four weeks, and all such should be looked upon with suspicion and be carefully investigated. These patients ascribe a great deal to "colds" that is simply due to the natural progress of the tuberculous process. Unless this erroneous idea is corrected, they will shut themselves up in the house and deny themselves the fresh air which is essential to their recovery.

6. It is unfortunate that we do not have any really definite, unmistakable sign of early tuberculosis, which presents itself in all cases. However, there is one symptom that does present it-

self often, of which I am sorry to say, advantage is not always taken. I refer to hæmoptysis. In a certain percentage of cases hæmoptysis is the first sign to the individual that he has any trouble. He goes to his physician who too often promptly relieves him of all anxiety and at the same time of the opportunity of getting well, by telling him "that it amounts to nothing, it was only from the throat." Throat hæmorrhages are very, very rare, and this initial hæmoptysis should be the means of calling attention to an existing tuberculous process, thus saving the life of nearly every individual in whom it occurs. But alas! this is not true. These patients are comforted by false hopes and lulled into a forgetfulness of their condition until the disease extends and they find themselves suffering from advanced tuberculosis. Now that we know of the curability of early tuberculosis, what a pity that the phrase "throat hæmorrhage" should ever have been coined! The time will shortly come, if, indeed, it is not already here, when it will be as culpable to tell a patient that an initial hæmoptysis is "from the throat" as it would be to treat appendicitis as "cramps." Every case of "blood spitting" should be considered as a case of tuberculosis, unless proved otherwise.

7. Pleurisy is a symptom that should be carefully watched. It is certainly tuberculous in many, many cases. Carefully compiled statistics show that many individuals who have active tuberculosis had a premonitory pleurisy months and often years before, and I would call attention to the necessity of carefully examining these patients for tuberculosis and of carefully watching them in after years.

8. A slow recovery after disease, especially after the acute febrile diseases, should be investigated for tuberculosis, for it is a frequent cause of slow recuperation, and during this period of low vitality, it often makes rapid progress.

I do not want to be understood as saying that it is an easy matter to detect incipient tuberculosis, for the physical examination of these cases is a delicate matter, the most difficult of all stethoscopic work. The point that I wish to emphasize is, that there are clinical symptoms present in the early period of nearly all cases, which force the exclusion of tuberculosis before a diagnosis can be made. The diagnosis will require the trained ear of one who frequently examines chests; and even then may have to be confirmed or disproved by the tuberculin test. In passing, let me emphasize the importance, the reliability, and the harmlessness of this important measure. I know it is feared by some; but how can a man

condemn this procedure on the ground of danger and advocate exploratory incisions with the double danger from the operation and the anæsthetic? In this connection, permit me to call attention to the recent studies of tuberculin made in the Saranac Laboratory, which confirm the harmlessness of this test.

EARLY TREATMENT.

When the diagnosis of tuberculosis is once made, what is to be done? This question may seem foolish, nevertheless it is well worthy of consideration. The tuberculous individual usually feels able to go about his work, and as a rule, is permitted to do so. Is this right? Is this justice to the patient and those dependent upon him, if such there be? Is it justice to the medical profession? Most emphatically it is not.

It is very unfortunate that the early symptoms of this disease are not sufficient to make the patient feel ill. If they were, the disease would be easier to cure; but since they are not, the burden is upon our profession. We must not allow the personal desires of the patient to militate against his recovery.

It is my practice to advise every person afflicted with pulmonary tuberculosis to desist from work for a time and to take energetic measures for regaining health, and I am happy to say that I have never had a case of tuberculosis develop in my practice and a patient die of the disease, since I have treated them in this way.

While tuberculosis is a curable disease, yet it is a serious one and it must not be treated lightly, for a life is threatened in every instance.

It is sometimes said that it is wrong to subject these early patients to the annoyance and expense of getting well, because they will often get well of their own accord. Let the innumerable deaths of those who have been neglected answer this supposed argument. If the physician was to treat only such patients as would be unable to live without his aid, he would be compelled to have the power of reading the future, and much of his usefulness would be eliminated. The man who makes this argument in case of tuberculosis must equally criticise the treatment of most cases of pneumonia, typhoid fever, and other acute febrile diseases. He must also condemn the operation for appendicitis and gallstones, especially during the quiescent stage, for how can he tell that these patients will ever have another attack, if they are let alone? We ask the exercise of the same judgment and common sense in dealing with tuberculosis that we do in dealing with other maladies; no more, no less; and we believe that we should fall short of our duty as physicians and

fail in our endeavors for our patients, if we should do otherwise than advise immediate treatment when the diagnosis of tuberculosis has been made; for, when the process is sufficiently extensive to cause recognizable signs, the chances are against the individual without intelligent help.

What should be the nature of this treatment? In the first place, it should be thorough. In order to be thorough, it must be carried out under the supervision of the physician, for there are very few people who will follow out a plan of treatment, if left to themselves, and especially is this true when they feel in fairly good health.

The best place to treat such patients is in a sanatorium, where they are forced to care for themselves, and where everything can be done to help restore their health. My patients often tell me that their physicians have told them that they were not really sick enough to go to a sanatorium. This comes from a misconception of the nature of such an institution. A sanatorium is a place to cure tuberculosis, and tuberculosis is most curable when treated in its incipency. In the history of a case of tuberculosis there is never a time when it is too early for sanatorium treatment.

Often when tuberculosis is diagnosed, the patient is ordered to the country or the mountains, or at least to make some change; and as a rule in these early cases the patient improves. Often the disease quiets down and the patient resumes his work. This has been accomplished by the sacrifice of a little time and at a comparative small expense.

Why not recommend this change then instead of institutional treatment? Let the after history of cases treated in the two ways tell. Tuberculosis is a disease which heals slowly. This so called recovery of health which follows change is often only apparent. It takes months to get well of incipient tuberculosis. The patient who simply makes a change of surroundings has only the change and rest from which to derive his benefit. He returns to work, knowing nothing of his disease or the things which are necessary to retain the health to which he has been apparently restored. On the other hand, the individual who has been treated in a thoroughly equipped institution has the benefit of the rest and change. He has appropriate food, the proper amount of rest and exercise, a thorough enforcement of the fresh air principle, and besides, has advantage of all active measures which science knows to be of value. He returns to work after a few months when all active symptoms have disappeared, but he well understands that it will take a year or

two to make the cure permanent. He is educated in the care of himself and thus prevents a relapse, while the individual who has simply made the change sooner or later is apt to break down again. His apparent saving has been a loss, and with it perhaps has come the loss of health and life as well.

It is positively wrong to send a patient with tuberculosis away from home to shift for himself before he has been thoroughly trained as to what to do. It is just as rational, and it would be no greater injustice to the individual, to allow a pneumonia or typhoid fever patient to shift for himself as to allow one suffering from pulmonary tuberculosis to do so. Individuals suffering from this disease often come to our western health resorts and tell how their physicians, upon discovering the disease, advised them to go away before another day rolled around, just as though there were a specific climate somewhere that would somehow in some mysterious manner cure them. How much better would a little wholesome, rational advice have been! The cure of tuberculosis must be based upon commonsense.

If a physician has not a sanatorium where he can take his patients, he can give them good training and intelligent treatment in their own homes and make them aware of the nature of the disease, and as to what is necessary to cure it. Then when trained he can send them away if necessary. When a change of climate is advised, the patient should be instructed to place himself in the hands of some competent physician when he arrives in the new country.

In treating tuberculosis, the first essential is for the patient to thoroughly understand that whether or not he gets well depends on his own individual effort. A physician cannot cure a tuberculous patient, but he can make it possible for the patient to cure himself.

In the way of treatment, these patients need fresh air all the time. If in our climate, they can live in a tent with open sides, or on an open porch. If they must stay in the house, they should have a light sunny room well ventilated, with several windows, if possible, and the bed should be drawn near the windows so as to get the fresh air.

The patient should be put through a process of hardening. He should be in the open air all the time; in winter it is usually unnecessary to raise the temperature of his room above 60°, except when he is dressing in the morning and when undressing, and he should have a cold sponge bath every morning. After a short period of such treatment he will never mention "draught" and will feel almost immune to "taking cold."

In passing, let me say a few words about the open air treatment of tuberculosis, which is emphasized from every quarter to-day. The lay press and the professional journals are full of "open air" treatment. This is all well and good. I am a thorough believer in it, but I believe it is time to sound an alarm and call a halt. The cause of the tuberculous patient is in danger of suffering great injury. Pure air is one of the essentials in treating tuberculosis, but it is not all. The idea is becoming prevalent that all that is necessary for the cure of tuberculosis is "open air." Nothing could be farther from the truth. These patients need most careful attention and guidance. The results from open air alone are not going to be satisfactory, and then there will be a revulsion of feeling, when the failure should not be laid to the measure, but to the method. The most absurd things are done in the name of open air. The teachings should go forth that open air is only one measure in the cure of this disease and that, to be most successful, it must be used intelligently and combined with other measures which are known to be of value.

As long as activity is present in the chest and as long as there is a rise of temperature, the patient should take very little exercise, especially should he avoid tiring. After these have subsided, then he should exercise by degrees until he is taking an equivalent of a several miles' walk each day.

These patients must have good nourishing food. Eggs, preferably raw, milk, and meat, together with a liberal amount of fat in the form of butter and bacon, should be the basis of the diet. Easily digested vegetables and fruits are also valuable in keeping the appetite from tiring. All indigestible food, pastry, and sweetmeats are to be studiously avoided. A very important measure in all these cases is hydrotherapy. The morning cold rub, the half bath, and the sheet bath are all measures that can be carried out in homes, and they are measures of great importance in treating the disease. They are excellent tonics to the nervous, circulatory, and respiratory systems, and have the effect of increasing the appetite, aiding the power of digestion, and promoting assimilation and excretion.

The tuberculin preparations in careful hands have shown themselves to be of great value. There is no question that they promote healing in tuberculous areas, and they undoubtedly confer a certain immunity upon those so treated.

The chemical rays of the spectrum, whether taken from the sun or an arc light seem also to be of value. The beneficial action is due perhaps

in part to the action of the light upon the blood, partly to its stimulating properties, partly to its germicidal effect. While this is something that cannot be utilized except with special apparatus, yet I wish to draw attention to it as a field of therapy well worthy of investigation.

These measures, just described, must not be used in any careless, haphazard manner, for they are all capable of doing harm as well as good. However, if they are employed with skill, after a careful study of the needs of each individual patient, they will afford either relief or cure to a very large percentage of tuberculous individuals. But it must be remembered that success in this field of therapy depends on a close attention to details. Things must not only be done, but they must be done to the right patient, at the right time, and in the right manner.

If tuberculosis is ever to be mastered, it must come through early diagnosis and immediate, energetic, rational treatment. To attain this end, the earnest cooperation of the entire medical profession is required.

THE ADDITION OF CALCIUM SALTS TO NUTRIENT BROTH. A RELIABLE AND CONVENIENT METHOD FOR GROWING THE PNEU- MOCOCCUS, MENINGO- COCCUS, AND CER- TAIN OTHER BACTERIA.*

By CHARLES BOLDUAN, M. D.,

NEW YORK,

RESEARCH LABORATORY, DEPARTMENT OF HEALTH.

During the course of some work on the pneumococcus carried on at the research laboratory the need was felt for a culture medium which did not contain any animal body fluids (ascitic fluid, blood serum, etc.). Plain broth was found almost worthless for the pneumococcus, for while one or two generations might grow if planted from blood agar, the growth soon died out, making continued transplantations from broth to broth impossible. Nor did careful neutralization of the broth to phenolphthalein nor even slight alkalization yield any better results. The addition of glucose, as is well known, does cause a luxuriant growth of the pneumococcus, but the production of acid in this case is so great that the cultures die very quickly and therefore need transplantation every few days. The writer felt that it might be possible to neutralize most of this acid as it was produced and thus obtain a broth

possessing all of the advantages of glucose broth without its disadvantages. For this purpose calcium carbonate was employed, at first in the form of powder and later, because of several advantages, in the form of pieces of marble.

A number of strains of pneumococcus were subjected to a critical comparative test in a series of about twenty different culture media. On transplanting the cultures every day or two it was soon found that certain of the media, although they yielded a profuse growth, were unreliable; i. e., a growth was not always obtained with each inoculation, even though the culture was still alive. In order to carry such a culture on it was often necessary to reinoculate from the same culture, using, however, a larger amount. Among these unreliable media were glucose broth and glucose broth plus marble. Curiously enough *plain broth with marble, but without glucose*, yielded a moderate growth unfaithfully with each transplantation.

On testing the acidity of the cultures in the various media it was found that large quantities of acid were developed in media containing glucose alone, or glucose and calcium carbonate, while small quantities of acid developed in ascitic broth or even in plain diluted ascitic fluid. The cultures in plain broth plus marble on the other hand were usually neutral, though a very small development of acid has been observed.

When plain broth is inoculated from an ascitic broth culture of pneumococcus, there frequently is not only no increase in organisms, but an actual decrease. When marble is present there is a growth right from the start. This fact cannot be reconciled with the assumption that the marble acts only by neutralizing acids formed. On reviewing these data Dr. Park suggested that the virtue of the marble might reside in the calcium and not merely in its neutralizing power. Two other salts of calcium, the chloride and the sulphate, were therefore tested. The former was used in solution, one part to two thousand of broth, the latter was used in pieces like the marble already mentioned. My experiments with these two salts indicate that *it is the calcium element, in part at least, which favors the growth of the pneumococcus*. Calcium carbonate (marble) and calcium sulphate (gypsum) are ordinarily regarded as insoluble in water. Nevertheless, a small trace of calcium must pass into solution in order to account for this effect on the growth of the pneumococcus. Since marble also serves to neutralize some of the acid formed, it would seem preferable to the other salts of calcium. Further experiments, however, are necessary to determine this point.

* Read before the New York Pathological Society.

As already stated pneumococcus cultures in media containing glucose die off very quickly. It was not found that the viability of such cultures was increased by the presence of the marble. This is not surprising, for our titrations showed that the marble failed to neutralize considerable quantities of acid. On the other hand, in plain broth plus calcium carbonate (marble broth) the cultures lived just about as long as those in ascitic broth. Out of three different strains tested, one was still alive at the end of thirty days. Out of four, three were still alive at the end of seventeen days.

A point of considerable importance is the effect produced by continued growth in a medium on the virulence of the organism. The cultures tested for this purpose had been grown for fourteen consecutive generations in marble broth. None of them seemed to have lost any virulence when compared with an ascitic broth culture made directly from the blood agar stock cultures.

A peculiarity of the marble broth cultures observed several times was the formation of short chains, while a control culture in ascitic broth showed only two's. Besides this, the absence of anything indicative of a capsule makes this medium a poor one for bringing out the characteristic morphology of the pneumococcus. On the other hand, cultures of the so called *Streptococcus mucosus capsulatus* when grown in this medium take on a form practically the same as that of an ordinary pneumococcus.

In preparing this medium, marble is broken up into small pieces in an iron mortar. The finer pieces are removed by screening through an ordinary wire crate. The others, about the size of small dice, are washed in water and one or two pieces placed into each tube. The tubes are then filled in the usual way with plain broth and sterilized in the autoclave.

In applying the results of these experiments to agar plates, it is well to employ calcium chloride (0.1 to 0.5 per cent.). The use of calcium carbonate powder produces an opaque plate on which the colonies can hardly be recognized.

From the foregoing it will be seen that marble broth is an extremely reliable medium for the pneumococcus, and can in very many cases replace ascitic broth. Its use obviates not only the tedious collection of ascitic fluid, but also the careful fractional Pasteurization which ascitic broth requires.

Marble broth can be used also for cultures of the meningococcus. The medium does not produce quite so luxuriant a growth as ascitic broth, but seems to be very reliable.

A CASE OF DIGITALIS POISONING WITH VERY LOW TEMPERATURE WITH-OUT COLLAPSE—RECOVERY.

By WILLIAM N. JOHNSON, M. D.,

PHILADELPHIA.

The following case presents the interesting and rather unusual phenomenon of having a very low temperature recorded after an overdose of tincture of digitalis, with no other symptoms of collapse:

Mrs. M., aged 65 years, of feeble sight and rather feeble mind, but yet capable of taking care of herself to a certain extent, has for years been afflicted with a myocardial degeneration, marked by occasional attacks of cardiac weakness and deranged digestion. For these symptoms her sovereign remedy has been aromatic spirits of ammonia, which she was accustomed to take herself, without consultation with the rest of the family, in doses of half a teaspoonful whenever she felt an attack impending. On the day previous to the present occasion she had emptied the contents of one bottle, which she supposed to be ammonia, into another bottle, which had a label of ammonia on it. The former bottle was thrown away, but one containing a highly concentrated tincture of digitalis could not be found, although it had been kept in one place which was supposedly safe. How much digitalis there had been in this bottle could not be ascertained.

On February 28, 1905, at 11 a. m., the patient helped herself to one half a teaspoonful of this mixture, according to her own statement, and again at 1 p. m. A few minutes after the second dose she had a rather violent attack of vomiting and diarrhoea (discharges not saved) and severe pain in the epigastrium, radiating to the back. She called to her daughter, who at once responded, and thought at first that her mother had one of her old attacks. When she was informed about the manœuvring with different bottles, she sent to a neighboring druggist the bottle from which the two doses had been taken, for analysis, but he, either through indifference or ignorance, did not analyze the contents. The vomiting and diarrhoea of the patient did not recur, but the daughter at once made an observation of the temperature and pulse, and found the former 94° and the latter 54. When I reached the house an hour afterwards I found them the same, although there were no other symptoms of collapse, such as air hunger, sweating, or a weak, thready pulse. The face was very pallid, but the pulse of good character, slow, and regular—a regular digitalis pulse. The temperature remained at 94° (axillary) for about an hour after I saw the patient, which was three hours after the second dose was taken. Under the influence of stimulants (ammonia and whisky) and external heat the temperature reacted, and complete recovery ensued.

6460 GERMANTOWN AVENUE.

American Therapeutical Society.—At the annual meeting of this society in Philadelphia Dr. Carl Beck was elected president.

IMMEDIATE ABDOMINAL SECTION.

By DENSLOW LEWIS, M. D.,

CHICAGO, ILL.

(Concluded from page 899.)

How shall we recognize obstruction of the bowels, or rather, what symptoms indicate the advisability or necessity of an immediate abdominal section? It may be acknowledged at once that we should operate very much more frequently than we do. The operation is more likely to be of benefit the earlier it is performed. If we wait for stercoraceous vomiting or for evidences of peritonitis we may have waited too long. Be the cause of the obstruction fecal impaction, volvulus, intussusception, constriction of the bowel by bands or adhesions, the strangulation of an internal hernia, occlusion of the calibre of the gut by tumors within or without the intestine, or the slipping of a knuckle of intestine through a slit in the omentum or mesentery, the ultimate result is the same. Expectancy is a poor makeshift for rational treatment, and the danger of delay is infinitely greater than the danger of an aseptic abdominal section which, in many instances, will alone permit the establishment of a positive diagnosis, at the same time that it allows the only proper treatment. In determining the time to operate, I suggest the advisability of operating in every case unless there is good reason why we should not. And then I would also suggest the advisability of operating when in doubt.

Gastric and duodenal ulcer are more frequent than commonly supposed. Fenwick found in 678 autopsies of gastric ulcer that perforation had occurred in 153 cases, or 23 per cent. (15). Premonitory symptoms are usually present—the ordinary symptoms of indigestion more or less pronounced—but in a good proportion of the recorded cases all symptoms are lacking and the patient may suddenly scream, fall to the floor, soon become unconscious, and die in a few hours (16). If the perforation be near the pylorus or in the duodenum the stomach contents may flow into the right kidney pouch and finally into the right iliac fossa, which accounts for the fact, as MacLaren has recently explained (17), that many of these cases are diagnosticated as appendicitis. Moynihan mentions fifty-one perforating duodenal ulcers; in many of these cases a mistaken diagnosis of appendicitis had been made (18). Dangerous hæmorrhage from the stomach may also occur without perforation. There may be vomiting of large quantities of blood, acute anæmia, quick and progressively weak pulse, sighing respiration, and great and increasing pallor. When

these symptoms occur there should be no delay. The certainty of diagnosis in most cases is impossible even by the most experienced, and I heartily applaud the sentiment of C. B. Keetley, who asserts (19) that any physician who in the face of these symptoms wastes valuable time in the attempt to make an accurate diagnosis is almost criminally responsible for the death which is sure to follow.

The abdomen should be opened at once and the source of the bleeding located, even if evisceration is necessary. The incision in the stomach may be made parallel with the greater curvature, about four inches in length, through the anterior wall, but if the ulcer is located on the posterior wall it may be reached through an opening in the mesocolon after lifting up the omentum and transverse colon. The ulcerating surface should be excised and the incision closed with two or three rows of sutures. In this connection no detailed statement can be made which will refer to the management of complications that may be encountered. Much will have been done if the dangerous hæmorrhage is controlled, for, at all events, immediate death is averted. The subsequent treatment will vary, but in many instances the need of drainage will be apparent.

Other conditions require consideration in this connection. The liver, pancreas, or urinary bladder may be ruptured; the spleen, common bile duct, or kidney may be torn, ovarian cysts may become twisted, gallstones or an enterolith may cause obstruction or rupture of the intestine; suppurative of the gall bladder may occur during typhoid fever or following labor. I maintain that the clinical history of many of these cases demonstrates conclusively the value of an early operation. I submit that a reference to medical literature will show to what an extent a mistaken or imperfect diagnosis has contributed to a fatal result in cases that could have been saved by a timely abdominal section.

Polakoff (20) relates a case of rupture of the liver in a man, aged 22 years, who was seized with an epileptic fit, during which he fell out of bed. The convulsions ceased and he fell asleep. On awaking he complained of intense pain about the right side, which was ascribed to the pulmonary inflammation (patient had croupous pneumonia), and accordingly on the next morning he was dry cupped. A few hours later he died, with symptoms of acute anæmia. At the post mortem the abdominal cavity was found to contain about five pints of serum, while the right side was occupied by large blood clots. The right lobe of the liver was torn across, the rent, which measured 6 cm. long by 2 deep, running parallel to and about 5 cm. from the right edge, and involving the peritoneal coat.

Wittauer (21) reports a case of perforated gastric ulcer in a man, aged 47 years, who was subject to epigastric pain for several years. He continued his occupation till six days before coming under observation. He then complained of pain in epigastrium; slight dullness at bases of lungs, with feeble breath sounds; abdomen distended; no tenderness, diagnosis, cancer of stomach. Three days later dyspnoea with rise of temperature; increase in dullness at right base. These signs increased and death ensued three days later. Necropsy showed perforated gastric ulcer, with subdiaphragmatic abscess and right pleural effusion. The same author reports a second case in a woman, aged 25 years, who also suffered from epigastric pain for several years. Finally, she experienced sudden abdominal pain while lifting a heavy weight. Three days later slight rise in temperature; pain increased. Exploration with needle in eleven places gave no result. Fourteen days later stinking pus found in left pleura—too late to operate. Patient died in a few hours. Necropsy showed perforated gastric ulcer with subdiaphragmatic abscess.

N. T. Mentin (22), of Warsaw, reports an intestinal concretion discovered post mortem in the cæcum of a woman who had been suffering from chronic intestinal catarrh, for which she had been treated by the internal administration of bismuth subnitrate. The concentration was 1 cm. long and chemical analysis showed it to be composed of eighty-five per cent. of bismuth subnitrate.

Bezançon (23) reports a fatal case of hepatic abscess, which during life had been diagnosed as cancer. Several ulcerations were found in the cæcum, to which fact probably the hepatic abscess was attributable.

Regaud (24) reports a liver abscess, the diagnosis of which remained doubtful during life, even exploratory puncture giving negative result. Post mortem, it was found that the whole right lobe was transformed into a purulent cavity containing about 1,200 grammes of very thick pus.

J. M. Byron (25) reports a liver abscess in which the diagnosis of empyema was made. An opening was made on the right side at the usual point and some pus withdrawn. The man died, and at the post mortem nothing was found in the pleural cavities, but in the posterior and upper part of the right lobe of the liver there was a very large abscess cavity, which communicated with the operation wound.

J. C. Pegram (26) reports two cases of perforating duodenal ulcer with subphrenic abscess. Case one was diagnosed as intestinal strangulation. Operation disclosed perforated duodenal ulcer admitting the end of the forefinger, and lying on the anterior wall near the pylorus. There was a subphrenic abscess holding at least two quarts of fluid. No attempt was made to close the ulcer, but instead it was walled off with gauze. The man died thirty-six hours later of general peritonitis. The other case, fatal without operation, presented the symptoms of perforative peritonitis. An opening about 1 cm. in diameter occupied the upper anterior part of the duodenum, almost

touching the pyloric orifice. Between the liver and diaphragm was a thick purulent collection.

Mester (27) reports a case of aneurysm of the hepatic artery occurring in a man who had been kicked in the abdomen by a horse. This had been followed by pain in the hypochondrium, intermittent jaundice, vomiting, and the passage of fresh or altered blood by the rectum. The patient died, and at the autopsy a false aneurysm of the right branch of the hepatic artery was found in the liver. It communicated with one of the hepatic ducts. He has collected nineteen cases from literature, which showed that the diagnosis is never made during life, the condition being mistaken for ulcer of the duodenum or for gallstones.

Havas (28) reports a case illustrating the fact that a normal bladder may rupture under the stress of acute complete retention of urine. A previously healthy laborer, aged 55 years, had two rigors on February 13th, since which date he passed neither urine, feces, nor flatus. On the 15th and 16th the patient himself applied hot fomentations to the abdomen; on the 16th three surgeons attempted unsuccessfully to pass the catheter. On the 17th he was admitted to the hospital, with symptoms of peritonitis. There was a prominence in the region of the bladder, but tympanitic resonance over it, except for three finger breadths above the symphysis. A catheter was passed without difficulty, but no urine obtained. Post mortem, urine was found in the peritoneal cavity. The renal pelves and the ureters were normal. On the posterior vesical wall there was a vertical laceration, over an inch in length, extending through the peritoneal coat. On the anterior wall of the prostate there was a gutter-like tear, covered with coagulum, which was directly continuous with a perforation of the membranous urethra, and was evidently a false passage made in the attempts at catheterism. The false passage was not connected with the rupture, since symptoms of peritonitis preceded the catheterism. The hypertrophied prostate appeared to be the cause of the retention.

Högarstedt (29) writes of those rare cases in which symptoms of the wound of the bladder do not develop for several days after the injury. In his case the patient, three days after a fall, suddenly experienced, in endeavoring to urinate, agonizing cutting pain in the region of the bladder, and was unable to micturate. The catheter withdrew a pint of urine containing many red blood corpuscles. After this the patient was absolutely unable to pass urine spontaneously, and seven days from the development of the first bladder symptom the patient died of peritonitis. This shows the importance of examining the urine for blood immediately following traumatism.

Hulke (30) reports difficulty of diagnosis of ruptured bladder in a man, aged 33 years, who was butted sharply in the abdomen, and immediately felt great pain. He had passed urine two hours previously. Resonant abdomen, signs of shock, but micturition impossible. Catheter withdrew urine slightly tinged with blood on several occasions. The shock seemed to have passed off,

and no rent was found by the catheter. The next day pain increased; the withdrawn urine was offensive; some vomiting. The following day symptoms of peritonitis appeared; laparotomy was performed. A rent, two and a half inches long, was found in the posterior wall of the bladder. The operation lasted two hours. The patient succumbed eighteen hours after. Autopsy showed peritonitis, but the suture of the bladder was proved to be water-tight.

Sieur (31) shows that the mortality from traumatic rupture of the bladder for a period of fifteen years (1879-1894) had been reduced from ninety to fifty-four per cent. This decrease was due to early operative interference. The two forms of rupture, the intraperitoneal and the extraperitoneal, have a different death rate. Thus, of 34 patients with intraperitoneal ruptures, 14 recovered and 20 died; of 18 with extraperitoneal ruptures, 10 recovered and 8 died. Sieur regards the following symptoms as the most important signs of intraperitoneal rupture of the bladder: A peculiar pain felt at the time of the injury, chilling of the surface of the body which persists for some time, an urgent desire to urinate which the patient cannot satisfy, the absence of any vesical swelling above the pubes, the absence of urine in the bladder, or its presence in small quantity.

E. Hurry Fenwick (32) says that all successful cases of intraperitoneal rupture of the bladder have been operated in within twenty-seven hours of the injury. The diagnosis is established upon the following data: History of a full bladder before and evidence of an empty bladder after receipt of the injury; the possible jerking passage of the eye of the catheter into the peritonæum through the rent, and the sudden withdrawal of bloody fluid. The point of the catheter being felt with undue distinctness through the abdominal wall. Treat the bladder wound with accurate Lembert sutures of fine carbolized Chinese silk.

Battle (33) records a case in a man, aged 40 years, who walked to the hospital three hours after having fallen fifteen feet. Moderate shock. Fractured tenth left rib. On second day, signs of internal hæmorrhage; four pints of saline infused, with much benefit. Laparotomy; 75 ounces of blood clot removed. Spleen torn and its chief vessels were tied. Peritonæum irrigated; five pints of saline infused, with great benefit. Did well for two days; then localized peritonitis, and death on sixth day.

Leith (34) reports cases of rupture of the pancreas. His first group includes those in which a fatal issue followed early upon injury; the symptoms were shock and collapse, and in no case did they point to the pancreas as the main seat of lesion. The absence of external lesions of the abdomen is important, and not a little surprising. Diagnosis is impossible without laparotomy;

therefore, treatment must be expectant or founded on the exploratory laparotomy. In case the latter operation has been performed, hæmorrhage may be arrested by pressure, and the ruptured ends brought close together by comparatively superficial sutures passing through little more than the peritoneal covering of the gland. The milder cases of pancreatic rupture may recover. Autopsies prove that this result may occur. After injury received in the epigastric region there may follow after a considerable interval of time a cyst in this region. The large proportion of pancreatic cysts are held to be of traumatic origin, and a table of seventeen such is given. The earliest tumor appeared ten days after injury; the latest eight years.

Battle (35) reports the case of a boy, aged 6 months, who had been run over by a cab. At first there were no definite signs of visceral injury; by the seventh day he was deeply jaundiced, with symptoms of acute peritonitis. Abdominal section was done on the eighth day, and a large quantity of almost pure bile evacuated, but no injury to the bile apparatus could be detected. He died on the ninth day, and, post mortem, the liver and gall bladder were found intact, but the common bile duct was found completely torn through.

Archibald Cuff (36) reports intestinal obstruction caused by an enterolith in a woman, aged 59 years. She had symptoms of obstruction. The abdomen was opened and a hard mass was felt within the bowel, about three feet from the ileocecal valve. The bowel was occluded on each side of the obstruction by the fingers of assistants; an incision was made opposite the mesenteric attachment, and a stone removed. The wound in the bowel and the abdominal incision were then closed. The patient died of exhaustion.

Maurice Richardson (37) reports two cases of wound of the kidney. In each of these cases only the liver and kidney were damaged. There was some bleeding into the abdominal cavity from hæmorrhage back of the peritonæum. In each case there had been complete perforation of the kidney, and some of its secreting structure had been destroyed. In each case it was necessary to make an extensive operation before determining what was to be done. In one case the renal vein and the pelvis of the kidney were very badly lacerated. In the other case they were uninjured. In the first case nephrectomy was performed, and death ensued. In the second case drainage was introduced and the patient recovered.

Dolérís (38) attended a woman who was delivered at the eighth month; temperature 102.2°, and on the second day of the puerperium it rose to 105°. Typhoid fever was suspected, but the curette was used. The uterus, however, proved healthy. Next day serum diagnosis seemed to prove that there was typhoid. A few days later a swelling developed over the region of the liver, and suppuration of the gall bladder was diagnosed. Abdominal section was performed, and much pus escaped from the gall bladder. The bacillus of Eberth was detected in the bile which

escaped from the wound during the first days which followed the operation.

Wyeth (39) reported the case of recurrent gallstone obstruction in which the gall bladder was found collapsed and empty at operation. The patient died unrelieved, and a post mortem examination revealed a small concretion in the peritoneal cavity, and a stricture of the hepatic duct where the stone had ulcerated its way through.

These cases show how death occurred because abdominal section was not performed in time. I have a list of other cases which show the advantage of a timely operation. I have instances of rupture of the kidney (40), rupture of the liver (41), intestinal obstruction due to gallstones (42, 43), and to an enterolith (44), where recovery ensued as the result of immediate operation. I refer especially to the 105 cases of gallstone obstruction reported by Kirmisson and Rochard (45), as additional evidence of the value of early surgical interference. I have notes of a case of recovery from suppurating cholecystitis occurring during typhoid fever (46), and another case showing recovery from an early operation for acute suppuration of the pancreas (47). Littlewood reports a successful operation for a traumatic cyst of the pancreas (48), and Nolan describes a recovery from an operation for abscess of the spleen during the puerperium (49). Mayo Robson tells us that in cases of ruptured gall bladder laparotomy is called for, "otherwise a fatal termination is almost inevitable" (50), and Thiersch reports a successful case where over forty pints of bile were removed from the abdominal cavity after the gall bladder had been ruptured by a blow (51). I have also a record of cases of rupture of the urinary bladder (52), rupture of the liver and kidney (53), and Mercadi's two cases of injury to the liver (54). In all of these cases recovery followed an early operation. I note Hochenegg's case of torsion of the omentum (55). Cortiguera's case of twisted pedicle of a cyst containing twenty pints of fluid (56), Winckel's case where fetal bones from an ectopic gestation were removed from a woman's bladder (57), and the case of Richelot and Pauchat where an ovarian cyst ruptured into the rectum (58). All these cases and many others that might be referred to show the advantage of an immediate operation.

Correspondence.

LETTER FROM LONDON.

The Teaching of Hygiene and Temperance in the Schools.—A Deputation to France.—Skin for Grafting to be Had for Money.—A Düsseldorf Experiment.—The Declining Birth Rate in Europe.

LONDON, April 17, 1905.

There was recently held at the Examination Hall, Victoria Embankment, a well attended conference of members of the medical profession to discuss the question of the promotion of the teaching of hygiene and temperance in elementary schools. Sir William Broadbent, who presided, said the movement had been initiated by nearly fifteen thousand medical practitioners, followed by a largely attended deputation to Lord Londonderry, who, while expressing sympathy, showed that the teachers in elementary schools were not as yet qualified to give instruction in hygiene. The training of teachers and the provision of suitable books were, therefore, the first questions to be considered. There was no doubt as to the necessity for the inclusion of such subjects in the curriculum of the schools. To be efficient, education must fit the child to earn its living; for this, health was necessary, and in the matter of health, the parents were for the most part ignorant and careless. Underlying and largely the cause of the physical degeneration was moral degeneration. At the root of both lay ignorance and vice, which must be combated.

Sir Victor Horsley said that continued success had followed the action taken by the medical profession in favor of teaching hygiene and temperance in elementary schools. The petition of the profession to the Board of Education had been

sent to the various educational authorities throughout the United Kingdom, and such a large number of bodies from different parts of the country had returned favorable replies that it was clear the movement was widely appreciated. Dr. Robert Jones drew attention to the report of the Inter-departmental Committee on physical deterioration as showing the intimate relationship which existed between ignorance of the laws of health and the use of alcohol and physical deterioration. People who had not food enough turned to drink to satisfy their cravings. Sir Thomas Barlow referred to the great change of opinion which had taken place during the past fifty years as to the value of alcohol in the treatment of disease. The changed attitude had, he thought, been brought about by increased knowledge coming from a multitude of varied experiences converging along the following lines: 1. Facts showing the widespread and insidious pathological effects of alcoholism. 2. Observations of the great overestimation of the value of alcohol in the treatment of disease. 3. The evidence that alcohol was not a necessity as an article of diet. He would be sorry, however, to be deprived of alcohol in conditions of collapse.

In this connection it is interesting to note that General Lord Methuen recently reported that the membership of the Army Temperance Association now comprised not less than one fourth of the British army, and in contrasting the present condition of the soldier with that of eleven years ago he showed that the change brought about by the influence of the temperance movement was remarkable. He declared that there was a higher tone, far less insubordination, and much less beer sold in the canteens than in former years.

A deputation of English physicians left London recently for Paris with the object of studying the condition of the poor of that city. Many of them are quartered at the Maison Laille in the rue des Ecoles, next to the quarters of the *Association générale des étudiants*. They are in the centre of things scholastic and medical, and if they gain nothing but the experience and the knowledge of French medical informality their visit will not be without advantage.

The skin grafting experiments which have been so successful of recent years have led to a new form of livelihood which is fairly remunerative, according to the British press. Several of the London hospitals have on their books the names of many men and women who have undertaken to sell portions of their skin whenever the necessity arises, and it is said that quite a traffic is now being done in the buying and selling of human skin. The persons who are willing to sacrifice their flesh

for money are by no means confined to the poor and destitute class.

Physicians here are watching with interest the experiment of the city of Düsseldorf, which has built a new public hospital and has made arrangements for an *Akademie für praktische Medizin* to be connected with it. It will have facilities for instruction in internal medicine, surgery, obstetrics, and infectious diseases and a fifth department devoted to pathological anatomy, etc. There will be subdepartments for diseases of the eye, nose, throat, and ear, for children's diseases, for cutaneous and nervous affections, and for the treatment of accidents. Physicians who wish to take up a specialty will be installed as assistants in the special departments, and after serving a certain number of years will be given a certificate as to their proficiency in their specialty. The training of nurses for the sick is also another task of the academy, with the holding of free graduate courses for all physicians and instruction of the public in matters of hygiene, but the principal purpose for which it is organized is to perfect the education of the graduates from the medical colleges, who are not allowed to practise until they have served a year in some hospital or allied official institution.

Whatever England may have to fear in the present, because of her isolated condition, however ominous the situation may appear in view of the difficulty with which she makes alliances and the comparative facility with which her enemies make them, there seems yet to be no dread for the future. The birth rate in England has by no means decreased so much as the birth rate of the other great European powers. France's condition is deplorable, and now Germany is following suit, for there has been a steady decrease in the number of births in Germany during the last few decades. From 1870 to 1880 the number of births was 40.7 for every thousand inhabitants, during the following decade it fell to 38.2, and from 1890 to 1900 it was not more than 37.4.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 909.)

Isophysostigmine is the name given to an alkaloid prepared by E. Merck from the portion of Calabar bean extract which is insoluble in ether. The alkaloid is chemically similar to physostigmine, but pharmacological experiments conducted by Professor Kobert showed it to be superior to physostigmine in promoting peristalsis; the emetic action of its sulphate is said to be quicker, stronger, and of longer duration than that of

physostigmine sulphate. Dr. Ogui, who gave the new alkaloid its name, considers that the proper dosage is three fourths that of physostigmine.

Isson is described as a pleasant, easily borne hæmatinic for children, the chief constituent of which is ferrous saccharate. It is given in doses of from 10 to 25 drops for children, and from one half to one teaspoonful for adults.

Hæminalbuminate Solution, introduced as a succedaneum for hæmalbumin, consists of iron albumin, 30 grammes; water, 652 grammes; tincture of vanilla, 5 grammes; arrak, 10 grammes; sweet spirit of nitre, 2 grammes; oleosaccharate of cumarin, 0.2 gramme; oleosaccharate of bitter almond oil, 0.4 gramme; oleosaccharate of rose oil, 0.4 gramme; alcohol, 100 grammes, and simple syrup, 200 grammes. The iron albumin, which appears to be a proprietary preparation, is dissolved in the water maintained at a lukewarm temperature and the other ingredients are then added.

Lentin is the shorter name adopted by E. Merck for metaphenyldiamine hydrochloride, which has been recommended in the treatment of diarrhœal conditions.

Lofotin is a hydroxyl-free codliver oil containing 0.01 per cent. of phosphorus.

Maceratio Renalina Porci, a remedy which has been recently proposed in the treatment of nephritis, is obtained from the kidney of the pig by the following process: A fresh kidney from a pig is cut into minute pieces, washed with fresh water to remove the residual urine, then hashed and pounded into pulp. This pulp is put into 300 grammes of fresh water, to which the physiological proportion of salt, 7.50 to 1000, has been added. It is then allowed to macerate for three hours, stirred occasionally, and kept in a cool place to avoid fermentation. The red water of the maceration is divided into three parts to be drunk by the patient during the day.

Magnesiumperhydrol is the name given by E. Merck to a magnesium dioxide compound of a nature evidently similar to biogen and hopogan, for it is said to form a white powder insoluble in water and consisting of 15 to 25 per cent. magnesium dioxide, MgO_2 , and 75 to 85 per cent. magnesia, MgO . According to investigations by Gilbert, Jomier, and Bertherand and Gautier, the preparation is recommended for internal use as a disinfectant and oxidizer in abnormal gastric and intestinal fermentative processes, and may be given in doses of from one half to one teaspoonful three to four times daily, half an hour before or after meals.

Maretin is a methyl acetanilide in which the acetyl group is substituted by the group $NH.NH.CONH_2$. In this last group the urea nucleus is so strongly combined that aniline is not liberated as a decomposition product. It forms white, glittering tasteless crystals, soluble to the extent of 1 to 1050 in water. It is given in doses of from 3 grains to 10 grains daily.

NEW YORK MEDICAL JOURNAL

AND

PHILADELPHIA MEDICAL JOURNAL.

A Weekly Review of Medicine.

ESTABLISHED IN 1855.

NEW YORK, SATURDAY, MAY 13, 1905.

THE REGULATION OF CHILD LABOR IN PENNSYLVANIA.

There has recently been enacted in Pennsylvania a law raising to fourteen years the age at which children may legally be put to work, and purging the age certificate system of the features hitherto prevailing that greatly favored deception and false swearing. The passage of this law, we understand, has been largely owing to the efforts of an organization known as the Pennsylvania Child Labor Committee. By the enactment of the law Pennsylvania puts herself on a par in this matter with Massachusetts, New York, and Illinois. We have often deprecated unnecessary legislation, but we believe that the new Pennsylvania law is one that was urgently required, and one that, properly executed, cannot fail to prove in the highest degree beneficial to the children of the State, and therefore to its future citizens.

The new law recognizes that there are instances in which a child's age cannot be positively ascertained from records, and in such instances it gives a certain discretionary power to the certifying official, based mainly on the child's length of attendance at school. The establishment of such a criterion points, perhaps, to the purpose on the part of the framers of the law to secure for all children a certain degree of school training. This is a most laudable purpose, one that in itself would

amply have justified the passage of the bill, but it is not the only reason for such a course, and from the physician's point of view it is not the chief one. The physical welfare of a child is the prime object in regulating the age at which it may be set to bodily work, and we must not load children of tender years with tasks that overtax their strength. It is unfortunate that the new Pennsylvania law exempts glass works and foundries to some extent from obedience to the general restrictions that it imposes, but there is good reason to hope that additional legislation remedying this defect will be effected within a comparatively short time.

FORMIC ACID AND FORMIC FEVER.

We are indeed reviving many of the therapeutic notions of the ancients, and in consequence resorting more and more to the animal kingdom for additions to our materia medica. In particular, the injunction "Consider the ant," has been duly followed by some of our French brethren, notably M. Clément, who practically revives the aqua magnanimitatis of the old pharmacopœias. The ant, as we all know, is a prodigy of strength, and the ant also furnishes formic acid. Putting two and two together, M. Clément led himself to the inference that that peculiar constituent of the ant's organism was the source of its strength, and he reasoned, further, that it might give strength to man. He tried it, and the valetudinarian whom the late Mr. Frank R. Stockton depicted as having been marvellously invigorated by an accidental inoculation with a minute portion of the blood of a redoubtable savage, found dried on a dagger with which he had been slain, was little less wonderful for his acquired prowess than, as the French newspapers assure us, have been the men to whom formic acid has been administered. Indeed, the acid and its sodium salt are said to effect the marvels that at one time were somewhat confidently expected of the late M. Brown-Séquard's testicle juice.

All at once, as it were, within a day or two, the weakling who takes formic acid at the rate of about thirty grains a day, well diluted with water or made into a formate by the addition of sodium bicarbonate, finds himself equal to the most un-

wanted exertion. This statement does not rest solely on M. Clément's observation; with proper reserve, it is substantiated by Dr. Raymond Belbèze (*Lyon médical*, April 23rd). M. Belbèze testifies to the invigorating effect of the acid; after the fatigue of a hard day's work, he says, it has carried him through protracted fencing bouts, and those of his friends who have taken it have astonished the fencing masters by their resistance. It had the same effect on a lady who was given to long excursions on the bicycle, and some neurasthenics—not all—upon whom he tried it found their condition decidedly ameliorated.

But this rose is not without its thorn. M. Belbèze describes a febrile reaction—"formic fever," as he calls it—which has shown itself in himself and in others to whom he has administered the acid. There is a transitory fever, accompanied by slight headache and by trifling obscurity of vision. The whole trouble, however, lasts only from half an hour to an hour and a half, and occasionally the blurred sight gives place to visual perception of unusual acuteness, so that outlines are extraordinarily well defined, and objects appear, as it were, less like things apart from the beholder. During the fever, moreover, there is an exaltation of the sensibility in general. The fever is without chills, and M. Belbèze compares it to the gentle febrile reaction that accompanies a small alveolar abscess. Surely there is not much to be dreaded in M. Belbèze's "formic fever," and we shall be much astonished if the fear of it deters anybody from trying formic acid as a restorative of muscular vigor.

MENSTRUATION AND ARTERIAL TENSION.

In a rough way, certain phenomena of cardiovascular erethism have long been observed in menstruating women, such as overaction of the heart, heightened arterial pulsation, flushing of the face, and turgidity of the thyroid gland. Recently M. Sabourin has treated of the connection between menstruation and pulmonary congestion. Still later, at a meeting of the Medical Society of the Paris Hospitals held on April 7th, M. Armand Siredey and Mlle. Marthe Francillon reported upon their systematic observations of the arterial tension during menstruation. Their communica-

tion is published in the society's *Bulletins et mémoires* for April 13th.

Their formal observations, those on which they base their report, were made upon thirty-one hospital patients under treatment for slight pelvic ailments, but menstruating normally or with only the most trifling deviations from the normal phenomena. In all the experiments they made use of Potain's sphygmomanometer. They constantly observed a decided and rather sudden increase of arterial tension at the beginning of a menstrual flow and a fall below the normal point toward the end of the flow. They give several graphic charts illustrative of their observations. In the first one, which may serve as well as any of the others for an example, the woman's normal tension appears to have been 15 cubic centimetres. On the first day of a free flow (preceded by a slight escape of blood) the tension began to rise, and in twenty-four hours it had reached 17; from that point it fell abruptly to 13 and then to 12.4, and with about equal suddenness rose again to the normal figure, 15.

The existence of slight disease of the uterine annexa seemed to have no influence on the tension curve, but it was found that age and temperament did have an effect, the phenomena being exaggerated in women approaching the menopause and in those described as of a neuroarthritic temperament, amounting toward the change of life, in some instances, almost to the symptoms of exophthalmic goitre.

The authors seem to us quite justified in remarking that the matter of menstrual increase of the vascular tension is of sufficient importance to be taken into account in general practice, in view of its probable connection with various congestive conditions, especially in women who are approaching the climacteric.

CEREBROSPINAL MENINGITIS.

This disease is peculiar in that its epidemics are sporadic and its sporadic cases endemic. In other words, it is a disease from which this country is never entirely free, which occurs with special frequency at irregular intervals, and which, nevertheless, fails to show the ready communicability and numerical incidence of most other in-

fectious diseases. For instance, it is commonly treated without quarantine in private houses or in hospital wards, and usually without consequent infection of other persons. The lack of contagiousness is in marked contrast to the severity of the infection when once recognizable, the mortality being from thirty to seventy-five per cent. However, it has lately been noticed that, as with diphtheria, the germs of this disease may be found in the noses of healthy persons or may be represented merely by slight symptoms of rhinitis.

From the practical, clinical standpoint, the ætiology of cerebrospinal meningitis is about the same as for death by lightning. More cases are encountered when a relatively greater number already exist in a community, just as death by lightning is more frequent in the seasons of electric storms. But in cerebrospinal meningitis persons escape after exposure to other cases and succumb without apparently having been exposed in any way, so that the sequence of cause and effect is even more irregular than in the case of lightning strokes.

From the bacteriological standpoint, Weichselbaum's *Diplococcus intracellularis meningitidis* may be accepted as the essential cause. A qualification must be made, however, similar to that which pertains to almost every other specific disease: The symptoms depend upon the anatomical lesion, which may be produced by other germs, among which may be mentioned the pneumococcus, the tubercle bacillus, the gonococcus, probably the Friedländer bacillus, the colon bacillus, *Bacillus capsulatus aerogenes*, and the various bacteria of sepsis. In recent epidemics cases carefully diagnosed clinically have been found to be due to the true specific germ in most instances. There can be no reasonable doubt, however, that sporadic cases are due in many instances to other germs, and, of course, the diagnosis is sometimes recorded without any justification.

A very important and often neglected phase of the ætiology of infectious diseases is the train of circumstances that lead to the implanting of the specific germ. In some diseases, notably the exanthemata, this phase of the ætiology is comparatively unimportant, because, if a susceptible individual is exposed to the germs—that is to say, en-

ters an environment in which they may reasonably be supposed to be present—infection usually occurs. In other cases, with almost universal susceptibility, the propinquity of the germs does not cause infection, on account of the necessity of a direct inoculation, as in the venereal diseases and those introduced by mosquitoes. Again, a considerable group of infections is semelincident—that is to say, one attack confers a lifelong immunity. But semelincident diseases affect almost all members of a community once, like measles and scarlet fever, or, if they do not, some special mode of infection is necessary, as in the case of typhoid fever, or there is a geographical limitation of the disease, as with cholera and Malta fever.

The severity and rarity of cerebrospinal meningitis place it in analogy with hydrophobia, tetanus, malignant cedema, equinia, and anthrax. Tetanus requires an anaerobic inoculation, but this entire group except cerebrospinal meningitis are diseases of lower animals, to which man seems to possess considerable resistance and to which he succumbs only from very direct exposure. Many animal parasites are infectious, at least so far as the deep tissues are concerned, only in certain stages of their life cycle, but exemption from infection on this account can obviously not apply to any bacterial disease.

It will be noted that cerebrospinal meningitis is a very peculiar and exceptional infection. So far as can be judged from negative evidence, its occurrence at seasons when flying insects are scarce, the bacterial nature of the parasite itself, and the finding of the germ in the nose, we may conclude that it is an air borne disease. Such diseases are, almost without exception, quite markedly contagious. Many of them are semelincident. Whether cerebrospinal meningitis is semelincident or not, it is difficult to state. Several apparently authentic cases of second attacks are recorded, but, aside from the loophole of an error in diagnosis, we know that occasional exceptions occur to the law of semelincident in general. Then, too, cerebrospinal meningitis is quite a rare disease, and not much over half of its victims survive, so that in any event we should expect that a second attack would be exceedingly rare, simply as a matter of mathematical chance.

The comparative immunity to this disease, so fatal when established, is also peculiar. Bad sanitation predisposes to the disease only by multiplying the chance of infection. Thus, while it is more common in slums, barracks, and camps, and apparently somewhat favored by fatigue, exposure to damp and cold, etc., such predisposition operates only to a slight degree, and, while an appreciable factor in a statistical study, is scarcely so in the individual case.

The analogy to various diseases indigenous—referring to the habitat of the germs—to the lower animals and rarely extending to man suggests that cerebrospinal meningitis may originate in an animal epidemic. Such a theory has never been promulgated, but in the *New York Medical Journal and Philadelphia Medical Journal*, for April 1, 1905, Paul Shekwana refers to a demonstration by H. Albert of the *Diplococcus intracellularis* in two brains from cattle involved in an epidemic in Iowa. If further evidence of this sort is found, it will readily explain, or rather bring into a well recognized though unexplained analogy, the relative immunity to a disease which is serious when once established.

Another hypothesis may be suggested: While lesions that may be compared approximately to pyæmic metastatic foci occur in cerebrospinal meningitis, the course of infection is in most instances from the nose and throat to the meninges and thence, if at all, to other foci. The local respiratory lesion is almost always insignificant. Hence, it is possible that what may be termed adequate infection depends to a very large and determining degree upon purely anatomical circumstances in the way of communication from the nose to the exterior of the meninges by air chambers, tributary either to the nares themselves or to the middle ear and Eustachian canal.

Cerebrospinal meningitis, like most other acute forms of meningitis, almost inevitably involves the subjacent centres. Thus the nervous symptoms are not the indirect results of pressure and irritation, but due to a localized lesion. It is perfectly possible that many cases of anterior poliomyelitis are due to *Diplococcus intracellularis* infection. In general, a specific disease—that is, one due to a special germ—has a pretty definite set of

symptoms, although atypical cases are frequent and although most specific diseases may be closely imitated by other germs involving the same foci. In a general sense, cerebrospinal meningitis has a fairly typical symptomatology which is the sum of the general infectious symptoms and those due to local involvement of nervous centres. In a definite sense, the only thing typical of the disease is its irregularity, since we may observe almost any conceivable combination of local involvements, and not only may they affect entirely different centres, but the degree of local involvement may alter the function in any way from exaltation to absolute paralysis.

Treatment is along three general lines: 1. The old fashioned meeting of indications largely by alkaloids whose physiological effect is the opposite of the functional changes noted. 2. Antisepsis by external applications and by salicylates, etc., administered by the mouth, subcutaneously, or by direct injection into the subdural space. 3. Specific serum treatment. None of these methods is thoroughly satisfactory, and, indeed, we may go so far as to say that all except the direct injection into the subdural space and the serum treatment have been tried and found wanting. These two methods are by no means established, and the former is somewhat dangerous, yet there is at least the comfort that they promise something for the future.

A. L. BENEDICT.

CONSTIPATION AND UTERINE DISEASE.

At a recent meeting of the Medicochirurgical Society of Paris (*Bulletin médical*, April 26th) M. Marchais very properly insisted on the necessity of a uterine examination in cases of habitual constipation of obscure ætiology in women. If any abnormality of the uterus was found, he said, it need not be very pronounced in order to be looked upon as accounting for the constipation, and its rectification would usually be effective in overcoming the intestinal trouble.

THE CALCUTTA LIBRARY OF SCIENCE.

Mr. H. C. Sarcar, M. B., of Tollygunge, who seems to have undertaken single handed the task of providing a public scientific library for Calcutta, has recently issued a circular showing that he has made encouraging progress in the first year of his enterprise, though he intimates that he has been hampered by lack of publicity and by defec-

tive confidence in the success of the library. We hope that both these impediments will soon be done away with. Mr. Sarcar depends upon authors and publishers to add to the library by contributions of scientific books and periodicals. He gives a list of nineteen gentlemen whom he counts among his supporters. Twelve of these are Americans, and all but one of the twelve are physicians. One is a Cuban physician, three belong to the medical profession of England, one is a German pharmacist, and two are gentlemen of Calcutta.

INFLAMMATION OF THE MESENTERY.

Apart from diseases of its lymphatic glands, it is not probable that much of a chapter on the pathology of the mesentery could be added to a textbook. However, in a recent Kiel thesis, Dr. F. Möller relates a case of ileus dependent on lesions of the lower portion of the ileum that he thinks were secondary to inflammation of the mesentery. It seems to us more probable that a commentator on Möller's thesis, Dr. Müller, of Dresden (*Zentralblatt für Chirurgie*, April 29th), is correct in interpreting the mesenteric lesions as secondary to those of the intestine.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 15th.—New York Academy of Medicine (Section in Ophthalmology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, May 16th.—New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, May 17th.—New York Society of Dermatology and Genitourinary Surgery (private); New York Academy of Medicine (Section in Genitourinary Diseases); Woman's Medical Association (New York Academy of Medicine); Medicolegal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, May 18th.—New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, May 19th.—New York Academy of Medicine (Section in Orthopaedic Surgery); New York East Side Physicians' Association; Manhattan Medical and Surgical Society (private); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynaecological Society.

NEW YORK.

Cerebrospinal Meningitis.—There have been 1,202 deaths from this disease in New York since January 1, 1905.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending May 6, 1905:

	May 6.		April 29.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	621	13	601	13
Diphtheria and croup.....	334	39	353	49
Scarlet fever.....	256	14	254	13
Smallpox	1	..
Chickenpox	137	..	62	..
Tuberculosis.....	414	181	438	204
Typhoid fever.....	31	10	39	10
Cerebrospinal meningitis.....	178	111	195	87
	1,971	368	1,943	376

The Sydenham Office Building.—The first anniversary of the opening of this office building for physicians, at No. 616 Madison Avenue, New York, was celebrated on Wednesday evening, May 10th.

Lebanon Hospital Training School for Nurses.—There has been already collected for this school some \$12,000. The space now used by the fifty nurses is needed for the use of patients who already number over 200, and a handsome annex is planned to cost \$60,000.

The New York College and Hospital for Women graduated the following on May 9th: Mary M. Benedict, Mary Ethel Broadnax, Ethel Dolinsky, Bertha Florence Johnson, Harriet Eliza Kenney, Gertrude Van de Mark, Adelaide Wallerstein, Jean M. Williams, and Eva Wilensky.

The National Society of Musical Therapeutics will hold the last meeting of the season at the residence of Miss Florence Guernsey, 180 West Fifty-ninth Street, Tuesday, May 16th, at 8.30 p. m. Subject to be discussed: Should Music Have an Acknowledged Place as a Therapeutical Agent? Discussion to be opened by the president, Miss Eva Augusta Vescelius, followed by J. Mount Bleyer, M. D., LL. D., Lacey Baker, M. S. B., Emmet C. Dent, M. D., Miss Jessie A. Fowler, J. Thornton Sibley, A. M., M. D. Ten minutes will be allowed each speaker. Musical illustrations will be rendered by Mr. Wesley Weyman. Our readers are cordially invited to be present.

The New York Academy of Medicine.—The Section in Medicine will meet on Tuesday, May 16, 1905, at 8.15 p. m. Order: Presentation of Cases and Specimens; Clinical Reports: A Case of Infective Cholangitis, by Dr. H. S. Paterson; A Case of Retrohepatic Abscess, by Dr. David Bovaird; papers: General subject, Epidemic Cerebrospinal Meningitis; Brief Statement of the Gross Pathology, by Dr. Harlow Brooks; Modes of Infection, by Dr. Charles Bolduan; The Present Work in the Department of Health, by Dr. John S. Billings, Jr. Discussion by Commissioner Dr. Thomas Darlington, Dr. Dunham, Dr. Nammack, Dr. Hodenpyl, Dr. Conner, Dr. Park, Dr. Huddleston, Dr. Fielder, Dr. Leiser, and others. Charles H. Lewis, M. D., chairman; E. E. Smith, M. D., secretary, 26 East Twenty-ninth Street.

The New Harlem Hospital.—Plans have been completed for the power house and ambulance

station for the grounds of a new Harlem hospital. The main building is at present under construction. It is expected that work upon them will begin at once. When the hospital is finished it will form one of the most complete institutions of its kind in the country. It is located in Lenox Avenue, between One Hundred and Thirty-sixth and One Hundred and Thirty-seventh Streets. The general block plan comprises a plot 410 feet long and 199 feet 10 inches wide. Four ambulances and a delivery wagon will be accommodated in the ambulance station. Provision is to be made for eight horses, with all the appliances for quick hitching. There will be quarters in this building for the male help.

The Additions to Bellevue Hospital.—The Board of Aldermen having concurred in the appropriation of \$850,000 made by the Board of Estimate and Apportionment, in March, for the beginning of work on the new Bellevue Hospital, it is now expected that the actual work of construction will be started toward the end of next month, though it may be deferred until early in July. The present estimate of the total cost is \$8,500,000, to be expended at the rate of about \$1,000,000 a year. Careful restudies of the first plans have been made by Dr. John W. Brannan, president of the board of trustees of Bellevue and Allied Hospitals; by the medical board of Bellevue; and by experienced hospital workers. Dr. Brannan has stated that many valuable suggestions had been obtained from women nurses in the hospital, whose practical experience gave them knowledge on points which others would be likely to neglect or not even to think about. In the new hospital there will be eleven pavilions containing wards for patients, six of these pavilions being for medical cases and the five others for surgical cases. This year's appropriation of \$850,000 is to be devoted to the construction of the southeast wing, containing two of the medical pavilions, and this sum is also intended to cover the fees of the architects and consulting engineers, and to defray the expense of contingencies. A comparatively new feature in hospital plans, and one that is considered very important, will be the observation wards for children on the ground floor of one of the pavilions. There will be six of these rooms, containing from one bed to ten beds each, or about thirty-five to forty beds in all. A convalescent ward, with a sunny exposure, will be on each floor of the southeast wing above the ground floor. These wards are intended for the benefit of patients who are able to move about and see their friends. Those who are acutely ill, through this provision will not be disturbed in their wards by the movements of the convalescents and the conversation of their visitors. A roof garden, occupying the whole top of the structure, will include a considerable space covered over with glass, so that patients able to visit it can have the benefit of the fresh air in rainy weather. If properly clothed, they can visit the roof to advantage in weather of every kind. A high parapet will enclose the roof garden, on which toilet rooms and lavatories will be acces-

sible. In order to get open air, however, the patients will not be obliged to go up in the elevator to the roof, under the care of an attendant. There will be one or more balconies, from six to ten feet wide, opening from each ward in the pavilions, reached through French windows extending to the floor, so that patients can walk out or be wheeled out or be rolled out in their beds. There will be enough space in the balconies (protected by ornamental iron work) to accommodate all the patients of a ward at one time.

PHILADELPHIA.

Personal.—Dr. Lewis H. Adler, Jr., of 1610 Arch Street, Philadelphia, was elected president of the Protological Society of America at its meeting held in Pittsburgh.

Presentation to Dr. W. S. Forbes.—On commencement day, June 2nd, the students of the Jefferson Medical College will present Dr. William S. Forbes with a life size portrait of himself as a testimonial for his efforts toward legalizing dissection in Pennsylvania. This year completes the twenty-sixth year that Dr. Forbes has held the chair of anatomy at Jefferson.

Charitable Bequests.—By the will of Miss Emma Frances Moffitt \$300.00 is bequeathed to the county branch of Rush Hospital at Malvene, Pa., for the benefit of the women patients.

By the will of Mrs. Clement B. Newbold \$5,000 is devised to the Home of the Merciful Saviour for Crippled Children, and \$5,000 to the maternity wards of the Hospital of the University of Pennsylvania.

Scientific Society Meetings for the Week Ending May 20, 1905.—Tuesday, May 16th, Dermatological Society; Academy of Natural Sciences. Wednesday, May 17th, Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants of Wills Hospital. Thursday, May 18th, Section in Gynecology, College of Physicians. Friday, May 19th, American Philosophical Society.

Marriages.—Dr. Arthur Fernandez Coca and Miss M. A. Clews were married on April 27th. Dr. and Mrs. Coca sailed for Europe on April 29th, where Dr. Coca expects to spend at least a year in postgraduate study.

Dr. William A. Weaver and Miss Irene Coates West were married on April 29th.

Dr. Norman W. Payne and Miss Margery Stadiger were married on April 29th.

Dr. C. Wilfred Powers, of Dubuque, Ia., and Miss Jane Glass were married on April 26th.

Deaths.—Dr. John Howard Pugh died at Burlington, N. J., on April 30th, of old age. Dr. Pugh graduated from the medical department of the University of Pennsylvania in 1852. During the Civil War, Dr. Pugh was on the staff of the United States General Hospital at Beverly; in 1876 he was elected to the House of Representatives. He was a member and president of the Burlington County Medical Society.

Dr. James B. Grady died in Los Angeles, Cal.,

of apoplexy, on May 1st. Dr. Grady graduated from Jefferson Medical College in 1873.

Dr. Elias B. Carey died at his home, 1824 Arch Street, on May 4th, aged 71 years.

Entertainments for Charity.—The New Century Quartette gave a concert at 1420 Chestnut Street, on May 1st, for the benefit of the White League.

A theatrical performance for the benefit of the Home for Aged Couples, at 1723 Francis Street, was given in the New Century Drawing Room on May 1st.

A living picture entertainment was given on April 25th at the Hotel Rudolf, Atlantic City, for the benefit of the Children's Outing Fund.

A musical tea was given at the Roosevelt, for the benefit of the House of the Holy Child for Colored Children on April 26th.

The fiftieth anniversary of the founding of the Jewish Foster Home and Orphan Asylum, Germantown, was celebrated with appropriate exercises on April 30th.

The Health of the City.—The following cases of transmissible diseases were reported to the Bureau of Health for the week ending April 29, 1905:

	Cases.	Deaths.
Typhoid fever.....	289	20
Scarlet fever.....	36	0
Chickenpox.....	57	1
Diphtheria.....	55	4
Cerebrospinal meningitis.....	8	1
Measles.....	69	9
Whooping cough.....	5	4
Tuberculosis of the lungs.....	31	70
Pneumonia.....	49	55
Erysipelas.....	3	0
Puerperal fever.....	1	4
Tetanus.....	1	1

The following deaths were reported from other transmissible diseases: Malarial fever, 1; tuberculosis, other than pulmonary tuberculosis, 23; diarrhoea and enteritis under two years, 8. The total deaths were 552, in an estimated population of 1,438,318; corresponding to an annual death rate of 19.96 per 1,000 population. The total infant mortality was 92; under one year, 76; between one and two years, 16. There were 36 still births; 23 males and 13 females. The temperatures and precipitation were about normal. There was a thunderstorm on the 27th.

Governor Vetoes the Osteopathic Bill.—On May 3rd Governor Pennypacker vetoed the bill licensing osteopaths and regulating the practice of osteopathy. The principal reason for the veto was that there is nothing in the bill to indicate what constitutes the science of osteopathy, and an effort to solve the query by an examination of the printed literature of the science is not very successful. In his veto message the Governor says: "The approval of this bill would appear to give the authority of the State to a system of practice in the healing art, which excludes the use of medicine and the use of surgery. Why should there be an attempt so to confine the operations of the mind? If both drugs and surgery are useless they may be rejected, but if they should at times be found to be beneficial why should any science for the enforcement of a theory make the effort to exclude their use? Should the bill be-

come a law, licenses would be issued by the State Board of Osteopathic Examiners and not by the Medical Council of Pennsylvania, which would be an anomaly in our legislation upon the subject." We referred to this bill on page 814 of our issue of April 22nd.

The Annual Report of St. Mary's Hospital, just issued, shows that during the year 1904, 908 patients were admitted to the medical wards, 890 to the surgical wards, and 83 to the gynecological wards. The deaths among the ward patients were 149, a mortality of 7.92 per cent. Three hundred and twenty-one operations were performed. In the out-patient department 8,091 patients made 22,726 visits, and 322 operations on the eye, ear, nose, and throat were done. St. Mary's Hospital is in that part of Philadelphia in which recently the majority of cases of typhoid fever have developed; according to this report, 113 patients suffering from typhoid fever were admitted during 1904, of whom 6 died and 7 were under treatment at the close of the year, a mortality of 5.48 per cent., which is a very good result. The pneumonia statistics are as follows: Pneumonia, 18; alcoholic pneumonia, 2; catarrhal, 29; lobar, 4. Of these, 2 patients died of alcoholic pneumonia, 7 of catarrhal pneumonia, and 2 of lobar pneumonia; a total of 53 cases treated and 11 deaths, a mortality of 20.75 per cent. These statistics show some inaccuracy in classification. The hospital has a very large fracture list, 283 fractures of various bones having been treated in the wards during the year. Of these patients 18 died, a mortality of 6.36 per cent.; of the deaths, 10 were due to fractures of the skull and 3 to fractures of the vertebral column.

GENERAL

Change of Address.—Dr. Charles R. Dickson, to 192 Bloor Street, West, Toronto, Canada.

Boston Society of Medical Improvement.—There will be a meeting of this society at the Medical Library on May 15th. Dr. J. Collins Warren will speak on Epochs in the History of Medicine, illustrated by the stereopticon.

The Linton District, Mo., Medical Society has elected the following officers: President, Dr. J. F. Flint, of Moline; first vice-president, Dr. J. N. Fisher, of Columbia; second vice-president, Dr. J. E. Jordan, of Rowena; secretary, Dr. Paul E. Coll, of Mexico; treasurer, Dr. R. W. Berry, of Mexico.

The Baltimore University Medical School has graduated the following: Edward W. Gardner, A. D. Lindmann, of New York; Max D. Bier, W. A. Dietrich, of New Jersey; M. A. Godfrey, Victor I. Shapiro, of Massachusetts; Thomas I. Kealy, A. J. Thome, John C. Kibler, of Pennsylvania; Z. A. Thompson, J. W. Webb, D. E. Ritter, S. W. Riddel, of West Virginia; Daniel H. Leddy, of Rhode Island.

Cleveland State Hospital.—The following nurses graduated from the training school on April 18th:

Covel Lee Fuller, Florence L. Dredge, Elizabeth M. Cottle, Charles H. Lerch, Elizabeth M. Hostetler, Lisa H. Murry, Charles P. Walsh, Emma L. Hartwell, Edith M. Bosley, Cyrus S. Miller, Charles R. Conway, Mae Hurley, Minnie Bowman, George H. Smith, Walter H. Groff, M. Zorah Starr, Frank F. Foy, Mary G. Vogt, Elizabeth Babcock, and Anna C. Gallagher.

Licensed to Practise Medicine in Minnesota.—The following physicians have been licensed to practise by the Minnesota State Board of Medical Examiners:

C. S. McKee, of Minneapolis; A. M. Cattanach, C. D. Conkey, of Superior, Wis.; H. Cannon, E. H. Bohland, of St. Paul; J. S. White, of Fort Snelling; D. Kalinoff, of Stillwater; F. R. Curney, of Chicago, Ill.; P. H. Sundt, of Pine River, Minn.; W. A. Eachern, of Sandstone, Minn.; J. H. Fowler, of Tower, Minn.; C. H. Wall, of Mellen, Wis.; F. A. Christensen, of Lake Mills, Ia.

The Farrand Training School for Nurses, of Detroit, Mich., has graduated the following young women:

Agnes L. Baetcke, of Brighton, Mich.; Elizabeth H. Heron, of Toledo, O.; Gertrude Barnes, of Ludington, Mich.; Agatha Bennett, of Chatham, Ont.; Laura B. George, of Constantine, Mich.; Laura B. Blanchard, of St. Johns, Mich.; Harriet K. Hunter, of Kalamazoo, Mich.; Lydia James, of Chicago, Ill.; Florence F. Sutton, of Toronto, Ont.; Nellie M. Sauer, of Bay City, Mich.; Grace Snively, of Benson, Ind.; Grace C. Shook, of Mt. Clemens, Mich.; Mary E. Daker, of Detroit, Mich.

St. Louis College of Physicians and Surgeons.—The following graduated from this college on April 14th:

E. C. Alvis, W. H. Alvis, E. W. Buhrmaster, F. Bechtler, J. H. Bridges, W. K. Chattle, A. C. Cautrell, N. Chostner, S. E. Cummings, G. E. Cook, J. F. Dixon, F. K. Doane, S. Donovan, C. R. Essex, J. W. Elders, C. E. Eisle, J. A. Fergus, John Fletcher, G. W. Gore, W. L. Gossage, O. Gilberson, William William, Z. C. Hagan, N. J. Haughton, A. J. Ihne, O. H. Jones, R. E. Jones, J. Kampe, J. A. King, L. N. Lindsey, G. L. McKinney, C. L. McClelland, A. V. Marquardt, R. G. Melinder, W. Mecke, C. D. Nobles, M. C. Pentz, Carl Puckett, G. H. Poos, G. F. Robinson, L. E. Rolens, J. M. Ross, L. Schulke, T. H. Shelton, F. M. Schroeder, W. E. Seba, I. Z. Stalberg, W. J. Shelton, Ed. Von Toll, W. R. Tweedy, J. R. Tweedy, H. A. Vise, M. M. Webster, J. A. Youngman, J. H. Ziegler.

New Swedish-American Hospital for Chicago.

—The new Swedish-American hospital which will be erected at the southeast corner of Sixtieth and Green Streets will be one of the most modern scientifically arranged institutions in the West. The cost will be about \$160,000. It will be located in the centre of a large Swedish residence district, and will fill a demand long existing in that part of the city. The plans provide for a five story and basement fireproof building, 100 by 125 feet, with two wings, a central building, and an open court facing the south and containing accommodation for 160 patients. The medical staff will consist of physicians in the city, independent of nationality, but the corps of nurses and the management of the hospital will be Swedish.

Personal.—Dr. S. H. Durgin has been reappointed a member of the Boston Board of Health, and also chairman of that board. This position Dr. Durgin has held for a number of years, and his strict attention to every detail in connection with the health in the city is abundant reason for the reappointment.

The faculty of the North Carolina Medical

College has been augmented by the following additions: Dr. F. M. Winchester, professor of obstetrics; Dr. R. E. Mason, professor of therapeutics; Dr. B. S. Moore, lecturer on surgery.

Dr. Charles B. Tefft, of Utica, has been elected president of the Alumni Association of Albany Medical College.

Dr. Theodore Schmalzreidt, of Springwells township, Mich., has been unanimously reappointed health officer for the ensuing year.

The following have been appointed as house physicians at the Albany Hospital: William Louis Hacker, of Albany; Thomas Joseph Flynn, of Johnstown; Edward Barnes Wilson, of Hudson; and Harry Stanton Rowe, Jr., of Cohoes.

The nomination of Dr. Carl A. Jackson, of Kansas, for city health officer has been confirmed. Dr. Jackson has had an experience in sanitary work that should especially fit him for the duties of health officer. He was assistant surgeon of the Forty-fourth United States Volunteer Infantry, and served three years in the Philippines.

Dr. E. H. Rorick, superintendent of the Athens Hospital for the Insane, has been chosen to succeed the late Dr. Gustavus A. Doren as superintendent of the institution for feeble minded youth, at Columbus, O., at a meeting of the board of trustees.

Statement of Mortality in Chicago for the Week Ending May 6, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	May 6, 1905.	April 29, 1905.	May 7, 1904.
Total deaths, all causes.....	530	527	539
Annual death rate per 1,000.....	13.88	13.80	14.58
By sexes.....			
Males.....	311	308	317
Females.....	219	219	222
By ages.....			
Under 1 year.....	93	121	73
Between 1 and 5 years.....	68	61	37
Over 60 years.....	88	97	127
Important causes of death.....			
Acute intestinal diseases.....	22	30	18
Apoplexy.....	12	14	20
Bright's disease.....	38	42	31
Bronchitis.....	14	20	19
Consumption.....	74	83	76
Cancer.....	15	30	19
Convulsions.....	15	8	7
Diphtheria.....	9	6	8
Heart diseases.....	45	36	43
Influenza.....	3	0	0
Measles.....	11	9	0
Nervous diseases.....	20	17	21
Pneumonia.....	57	74	120
Scarlet fever.....	1	0	4
Smallpox.....	3	0	0
Suicide.....	11	6	6
Typhoid fever.....	5	3	6
Violence (other than suicide).....	40	21	32
Whooping cough.....	13	7	7
All other causes.....	84	99	109

Despite an unusual number of deaths reported from violence, 11 from suicide and 40 from other forms, the total from all causes during the week is but 3 more than the total for the previous week. Pneumonia has temporarily again assumed the lead, with 85 deaths, while consumption has fallen from the 83 of the week before to 74. No marked changes among other important causes of death are noted, and the generally satisfactory conditions of the previous month still continue, except, of course, as to measles and whooping cough. The deaths of children under five years of age are 21 fewer than during the week of April 29th.

American Gynecological Society.—The thirtieth annual meeting of this society will be held at Niagara Falls on May 25, 26, and 27, 1905, in the Cataract House, the profession being cordially invited to attend. The following papers have been promised:

Accidental Rupture of the Uterus, by Dr. George W. Jarman; Retroversion Uteri—A New Operation for Radical Cure, by Dr. Arthur W. Johnstone; A New Plan of Procedure in Retrouterine Displacement, by Dr. E. E. Montgomery; Arteriosclerosis of the Uterus as a Factor in Uterine Hemorrhage, by Dr. Palmer Findley; Postoperative Vomiting, by Dr. Eugene Boise; Uniformity in Pelvic and Cranial Measurements, report of committee, Dr. King, Dr. Williams, and Dr. Davis; "Symposium," The Relation of the Appendix to Pelvic Disease or to Pregnancy; Relation to Pelvic Disease, by Dr. Reuben Peterson; Relation to Pelvic Disease, by Dr. Hunter Robb; Relation to Pregnancy, by Dr. Henry C. Coe; Relation to Pregnancy, by Dr. A. Laphorne Smith; Relation to Pregnancy, by Dr. J. Clarence Webster; Overlapping of the Fasciae in Closure of Wounds of the Abdominal Wall, by Dr. Charles P. Noble; "Symposium," The Radical Abdominal Operation versus the Vaginal Operation for Carcinoma of the Uterus; The Vaginal Operation, by Dr. Carlton C. Frederick; The Vaginal Operation, by Dr. George Gellhorn; The Vaginal Operation, by Dr. Fernand Henrotin; The President's Address, by Dr. Emelius C. Dudley; The Mortality in Operations for Fibroid Tumors of the Uterus, by Dr. J. Montgomery Baldy; Migratory Uterine Fibroids, by Dr. Reuben Peterson; "Symposium," The Toxæmia of Pregnancy; Clinical Types of Pregnancy Toxæmia, by Dr. J. Clifton Edgar; Renal Insufficiency, by Dr. Henry C. Coe; Pernicious Vomiting of Pregnancy, by Dr. J. Whitridge Williams; Eclampsia and Its Treatment, by Dr. Cyrus A. Kirkley; The Treatment of Eclampsia, by Dr. Franklin Spilman Newell; Vaginal Cesarean Section in Cases of Eclampsia, by Dr. Henry D. Fry; The Mortality of Operations, Other Than Strumectomy, in Cases of Exophthalmic Goitre, with Special Reference to Gynecological Operations, by Dr. Barton Cooke Hirst; Sudden Death During or Immediately After the Termination of Pregnancy or Operation on the Pelvic Organs in Women, by Dr. Edward P. Davis; The Technique of an Operation for Large Rectocele, by Dr. George H. Noble; The Surgical Treatment of Ulcer of the Stomach, by Dr. William H. Wathen; The Present Status of Electricity as a Therapeutic Agent in Gynecology, by Dr. Chauncy D. Palmer; The Third Ovary, by Dr. W. P. Manton; The Repair of Injuries to the Ureter, by Dr. Florian Krug.

Illinois State Medical Society.—The fifty-fifth annual meeting of this society will be held at Rock Island, May 16, 17, and 18, 1905, when the following papers are expected to be heard:

Address, by Dr. J. W. Pettit, What We Must Learn and Unlearn in the Treatment of Tuberculosis; Present Status of Serum Therapy, by Dr. E. R. Larned; Practical Significance of Certain Common Symptoms in the Upper Abdomen, by Dr. J. F. Percy; Indormescent Shock, by Dr. H. T. Patrick; The Consideration of Late Hereditary Syphilis, by Dr. R. R. Campbell; Percentage Modification of Milk in the Home, by Dr. Charles R. Spicer; The Tuberculosis Problem in Illinois, by Dr. Homer M. Thomas; The Importance of Diet in the Treatment of Tuberculosis, by Dr. Adella Sater; Mixed Infection in Tuberculosis, with Some Consideration as to Treatment, by Dr. Ethan A. Gray; Climatic Treatment of Tuberculosis, with Special Reference to Colorado, by Dr. C. L. Wheaton; Typhoid Fever, by Dr. G. G. Craig; Diagnosis of Smallpox (lantern slides), by Dr. Heman Spaulding; The Value of Isnordia Palustris in the Treatment of Erysipelas. Report of Cases, by Dr. H. C. Mitchell; Pericarditis, by Dr. J. H. Bacon; Scrofula, by Dr. H. G. Anthony; The License and Control of the Practice of Medicine in the State of Illinois, by Dr. George W. Webster; Diagnosis of Chronic Nephritis, by Dr. Charles L. Mix; Ocular Manifestations of Chronic Nephritis, by Dr. Leigh E. Schwarz; Medical Treatment of Chronic Nephritis, by Dr. A. R. Elliott; Results of Surgical Treatment of Chronic Nephritis, by Dr. A. H. Ferguson; Report of Three Cases of Intermittent Claudication, by Dr. S. R. Pietrowicz, of Chicago; The

Glycosuria of Hepatic Insufficiency, by Dr. A. C. Crofton; Respiratory Oxidation Stimulants in Nephritis; Pulmonary and Allied Crises, by Dr. George F. Butler; Febrile Symptoms of Hepatic Syphilis, by Dr. Joseph L. Miller; Parenchymatous Keratitis and Subsequent Iridochorioiditis with Loss of Vision, by Dr. Charles H. Brobst; Syphilitic Meningitis in Children, by Dr. W. J. Butler; Educational Treatment of Neurosthenics, by Dr. Charles D. Center; Gastric Fatigue, by Dr. F. B. Turk; Some Phases of Disturbed Metabolism, by Dr. R. W. Webster; Some Eye Problems the General Practitioner is Called Upon to Solve, by Dr. R. J. Tivnen; Variola, by Dr. L. A. McFadden; Poisoning from Oil of Wintergreen, by Dr. F. C. Vandervort; X Ray in Leucæmia, by Dr. J. A. Capps and Dr. J. F. Smith; Pulmonary Edema Following Thoracentesis, with Report of a Case, by Dr. S. W. Miller; Air Examinations: Their Importance and Results, by Dr. A. Gehrman; Intestinal Parasites, by Dr. F. Smith; Address, by Dr. Fernand Henrotin, The Commerce of Surgery; "Symposium" on Surgery of the Upper Abdomen: Surgery of the Stomach, by Dr. Arthur Dean Bevan; Surgery of the Bile Tracts, by Dr. Carl Black; The Emergencies of Pancreatic Surgery, by Dr. Weller Van Hook; Surgery of the Duodenum, by Dr. Emerson W. Sutton; The Surgical Treatment of Injuries to the Spleen, due to Subcutaneous Penetrating Wounds; the Value of Splenectomy in Certain Anæmias Associated with Enlargements of the Spleen, by Dr. M. L. Harris; discussion opened by Dr. D. W. Graham; Surgical Tuberculosis, by Dr. William E. Guthrie; Tuberculous Nephritis. Review of Literature and Report of Case, by Dr. Robert Christie; Some Errors in the Diagnosis of Abdominal Troubles, by Dr. Clifford U. Collins; Congenital Club Foot, by Dr. John Ridlon and Dr. Charles E. Eikenbury; Malignancy in Uterine Myomata, by Dr. Henry F. Lewis; Reports of Cases, by Dr. S. C. Plummer; Strictures of the Esophagus Following Typhoid Fever; Colloid Carcinoma of Cæcum; Penetrating Wound of Liver; Gastroenteroptosis; Practical Remarks Concerning When and How to Treat Septic Pelvic Affections of Women by Vaginal Incision and Drainage, by Dr. Fernand Henrotin; "Symposium" on Surgery of the Nervous System: Diagnosis and Pathology of Neoplasms of the Brain, by Dr. Hugh T. Patrick; Surgery of Cerebral Neoplasms, by Dr. L. L. McArthur; Insanity Following Skull Injuries, by Dr. E. Mammen; Cerebral Infection from Middle Ear Disease, by Dr. Norval H. Pierce; Pathology and Diagnosis of Lesions of the Spinal Cord and Peripheral Nerves, by Dr. Frank P. Norbury; Surgery of the Spinal Cord and Peripheral Nerves, by Dr. J. B. Murphy; discussion opened by Dr. Archibald Church; Plastic Surgery of the Trachea, by Dr. Albert I. Bouffleur; Pelvic Deformity Due to Congenital Dislocation of the Hips and Cesarean Section, by Dr. C. E. Paddock; Infectious Urethritis of the Non-Gonorrhœal Type, by Dr. P. Kreissel; Prophylaxis of Syphilis, by Dr. Alfred Schalek; Perigastric Adhesions After Gallstone Operations: Their Surgical Importance, and a New Operation for Their Relief, by Dr. E. Wyllis Andrews; Are Cases Demanding Removal of the Eye of Interest to the Surgeon and Physician by Dr. J. Brown Loring; Some Considerations Relative to Phlegmon of the Orbit, by Dr. Charles H. Bard; The Indications for Opening the Mastoid Process in Cases of Empyema of the Cells Following Acute Otitis Media, Where There is an Absence of Signs Over the External Surface of the Mastoid, by Dr. George E. Shambaugh; "Symposium" on Lacerations of the Obstetrical Canal, Resulting from Obstetrical Injuries: Pathological Anatomy, by Dr. J. Clarence Webster; Causes and Prevention, by Dr. F. H. Kimball; Diagnosis and Treatment of Rupture of the Uterus, by Dr. George Schmauch; Lacerations of the Vaginal Portions of the Uterus and Fornix Vagina, by Dr. L. H. Nickerson; Diagnosis and Treatment of Lacerations of the Vaginal Body, and of the Peripheral Region, Including the Pelvic Diaphragm, by Dr. C. S. Bacon; discussion opened by Dr. Joseph B. De Lee; The Value and Place of Duodenocolicotomy in Gallstone Surgery, by Dr. John C. Hancock; Postoperative Complications, by Dr. Daniel M. Eisendrath; Pelvic Infections in Women, by Dr. Thomas J. Watkins; Inversion of the Uterus, with Report of Cases, by Dr. P. L. Markley; Bronchoscopy for Removal of Foreign Bodies from the Air Passages, by Dr. E. Fletcher Ingals; Acute Dilatation of the Stomach, by Dr. A. E. Halstead; Tuberculous Subchorial Hematomata of the Decidua, by Dr. S. R. Hopkins; Intussusception in Infancy and Childhood, with Collection of 1,028 Cases, with Statistics, by Dr. J. H. Hess.

Pith of Current Literature

PRESSE MEDICALE.

April 5, 1905.

1. Surgical Intervention in Appendicitis, By J. L. FAURE.
2. Floating Liver, By ALBERT MARTINET.

1. **Appendicitis.**—Faure discusses the objections which have been made to surgical intervention. He considers the different forms of this disease, and presents a strong argument in favor of surgical treatment.

2. **Floating Liver.**—Martinet reproduces briefly the salient points made by Prentiss on this subject in the *American Journal of Obstetrics*, for May, 1904.

April 8, 1905.

General Paralysis and Syphilis, By L. MARCHAND.

General Paralysis and Syphilis.—Marchand gives in tabulated form the opinions of various writers between 1880 and 1902, which shows a wide disagreement as to the frequency with which syphilis is the causes of general paralysis. The table shows the extremes to be 7 per cent. and 94 per cent., the average 52.5 per cent. He then discusses cases from clinical, pathological, and therapeutic standpoints, but after all his conclusion seems to be that most are and some are not syphilitic in their origin, the same as that of all the other writers, and he makes no attempt to settle the only question really mooted, that of the proportion between the syphilitic and non-syphilitic cases.

April 12, 1905.

1. Cytology of Mumps, By J. A. SICARD and CH. DOPTER.
2. Obstetrics and Legal Medicine. Professional Secrecy and Criminal Abortion, By P. A. LOP.

1. **Cytology of Mumps.**—Sicard and Dopter find in the first stage, during the first two hours of the disease, numerous polynucleated cells, lymphocytes, and large mononucleated cells. In the second stage the glandular elements predominate. In the third stage, when glandular tumefaction is diminishing, the cells grow fewer in number. The lymphocytes and the large mononucleated cells are the last to disappear.

2. **Obstetrics and Legal Medicine.**—Lop quotes the French laws which define professional secrecy and impose penalties for its violation and then passes to the subject of criminal abortion. Finally he discusses the question whether a physician is ever justified in violating professional secrecy in order to secure conviction of a person who has been guilty of criminal abortion.

BERLINER KLINISCHE WOCHENSCHRIFT.

March 27, 1905.

1. The Parasitic Theory of the Origin of Cancer, By E. VON LEYDEN.
2. The Biogenetic Theory of Tumors and the Ætiology of Cancer, By O. ISRAEL.
3. Hydrotherapy, By L. BRIEGER.
4. Relations Between Balneology and Surgery, By F. KRAUSE.

5. Chronic Pulmonary Inflammations in Cardiac Disease, By D. ROTHSCHILD.
6. The Origin of Malignant Neoplasms, By VON HANSEMANN.
7. Manual Garcia, By P. HEYMANN.
8. Treatment of Flatfoot, By C. HELBIG.

1. **Parasitic Theory of Cancer.**—Von Leyden reviews the various theories advanced to explain the origin of cancer. He says that Cohnheim's theory is now practically disregarded. He cannot comprehend Ribbert's theory that, on account of some stimulus of unknown origin, normal cells suddenly take on a malignant character. Epidemics of cancer, the manner of its metastases, race disposition, and inoculability all tend to prove the infectious character of the disease. He believes that cancer originates locally always, and it attacks portions of the body which come into contact with the external world—the breasts, the gastrointestinal tract, the genital organs, the lungs, the face, and the lips. From all these considerations he is disposed to regard cancer as an infectious—that is, parasitic disease.

2. **Biogenetic Theory of Cancer.**—Israel contends that the entrance of a parasite into a cell causes a destruction either of the cell or of the organism, but that there is no evidence that it can cause cell proliferation. He inclines to the belief that cancer represents excessive cell production as is shown in the regenerative processes, in which the production of cells is always greater than is essential for the part affected.

5. **Pulmonary Disease in Cardiacs.**—Rothschild calls attention to Rokitsansky's dictum that certain cardiac and pulmonary diseases exclude each other. Difficulty in the venous return from the lungs is prophylactic, in a high degree, of pulmonary disease, as is seen, for instance, in the immunity from tuberculosis of those suffering from mitral stenosis. Tuberculous persons, however, can acquire other diseases which lead to valvular disease, but the latter acts favorably upon the tuberculosis. The good effect of rest in bed upon tuberculous disease of the lungs depends in a measure upon the pulmonary hyperæmia, which is coincident with the recumbent posture. All other forms of pulmonary inflammation are very frequently associated with cardiac, pleural, and pericardial disease.

6. **The Origin of Cancer.**—Von Hansemann declares that we have absolutely no data upon which to base a theory of the origin of cancer that will hold. Heredity has never been shown to have a potent influence. If it had, the teratoid tumors would be most often inherited, and this has not been shown to be so. The traumatic theory is not sufficient to explain all cases, either chemical, mechanical, or thermal. The occasional sequel of a cancer following an injury offers no scientific explanation for the origin of the disease. He says the infectious character of cancer has long been theorized about. There is absolutely no proof for it. Those who adhere to this belief either do not know cancerous tissue when they see it, or they are very vague in their descriptions of the parasites. They do not allege them

to be vegetable, since the bacteria are too well known; animal protozoa are not sufficiently known, so that they still lend themselves to the mysterious. [The paper should be read in the original for its details.—Ed.]

8. **Flatfoot.**—Helbing shows diagrammatically the development of flat foot and recommends Lange's celluloid plates for its treatment. He says that abduction of the ankle is the first and surest sign of beginning flatfoot.

April 3, 1905.

1. Diagnosis and Treatment of Internal Diseases by the Röntgen Rays (*To be concluded*), By R. VON JAKSCH.
2. Experimental Observations on Renal Dropsy, By P. F. RICHTER.
3. Treatment of Tropical Anæmia and the Anæmia of Ankylostomiasis, By O. LIERMBERGER.
4. Relations Between Surgery and Balneology, By F. KRAUSE.
5. Disinfection of the Utensils of the Sick, By G. MEYER.
6. The Newer Hypnotics, By A. MAAS.

2. **Renal Dropsy.**—Richter says that it is not yet proved that the retention of the chlorides is essential for the production of the dropsy of renal disease. His experiments on animals show that the ingestion of fluids plays an important rôle. He induced nephritis with serous dropsy by the injection of uranium nitrate and succeeded in showing that the ingestion of milk or mineral water favored the development of the dropsy. Dropsical effusions could also be influenced by the regulation of the ingestion of sodium chloride.

3. **Tropical Anæmia.**—Liermberger treated five persons in one family suffering from the anæmia of ankylostomiasis, very successfully with Levico—arsenic—iron water. Even before the worms were expelled, a decided improvement was evident in the blood examination and the general condition. He warmly commends this remedy in the treatment of all anæmias, due to tropical diseases, especially malaria.

6. **The New Hypnotics.**—Maas believes chloral fulfils ideally the requisites demanded of a safe and sure hypnotic. He discusses veronal, isopral, and neuronal. The first is a good hypnotic, but sometimes produces exanthemata; among its advantages are its diuretic action and its favorable influence upon the sweating of phthisical patients. Isopral sometimes causes gastrointestinal disturbances, and has some action on the heart. Neuronal contains a high percentage of bromides and has no advantage over many other hypnotics. The ideal remedy to produce sleep has not yet been found.

April 10, 1905.

1. Digestive Diseases and Balneology, By C. A. EWALD.
2. Poisoning by Sulphur Alkalies, By G. STADELMANN.
3. Mistakes in Hydrotherapy, By WINTERNITZ.
4. Experimental Hydræmnios in Nephritis, By E. BIBERGEIL.
5. Aim and Purpose of Balneotherapy, By F. FRANKENHAUSER.
6. Dysentery—Aggressive, By Y. KIKUCHI.

7. Diagnosis and Treatment of Internal Diseases by the Röntgen Rays, By R. VON JAKSCH.
8. The Diagnostic and Therapeutic Use of Exploratory Puncture in Internal Medicine, By O. DE LA CAMP.

1. **Digestive Diseases and Balneology.**—Ewald speaks somewhat discouragingly of the various water cures for the gastrointestinal diseases. The various conditions and the hydrotherapeutic measures employed for them are not yet clearly worked out and such means as are employed are largely empirical.

2. **Poisoning by Sulphur Alkalies.**—Stadelmann calls attention to the fact that poisoning by these chemicals varies from time to time, depending upon what form is most accessible to the public. Lysol is at present the most common form. He describes a severe case of poisoning with calcium sulphate mixed with calcium hydrate. Treatment consists in rapid gastric lavage, purges, and the administration of bismuth.

3. **Errors in Water Cures.**—Winternitz says the most common mistake is made with reference to the temperature. The more different the temperature of the water, under conditions otherwise the same, which comes into contact with the body, the stronger is the resistance of the organism toward the loss or gain of heat. Another mistake lies in the choice of the mechanical stimulant used. When water is used for defervescent purposes, it is wrong to begin with too low a temperature, to use too little mechanical irritation (friction) and to employ the bath for too short a time. In severe acute infectious diseases, the action of the water cannot be judged exclusively by its effect upon the temperature. In cases of collapse with cardiac weakness, the trunk should have cold compresses placed about it, while the extremities must be energetically heated. It is a blunder to use water at too high a temperature in the treatment of the anæmic, the chlorotic, and the convalescent. In giving Sitz baths, loss of heat from that part of the body which is not in the water, can be avoided by thoroughly wrapping it in blankets.

4. **Experimental Hydræmnios.**—Bibergeil succeeded in inducing nephritis in pregnant animals by injecting uranium nitrate and in inducing a condition of hydræmnios. The foetuses even showed dropsical effects.

7. **Röntgen Ray Diagnosis.**—Von Jaksch says that the Röntgen rays are now of use in internal medicine. He places special value in having the rays penetrate the body in every possible direction. He has found this method of especial value in the diagnosis of pulmonary tuberculosis and also in pneumonia. Pleural exudates, cardiac affections, and pulmonary tumors lend themselves readily to this form of examination. For the examination of the heart, he prefers radioscropy to radiography. The author does not think much can be gained by the treatment of internal diseases by the rays.

8. **Exploratory Puncture.**—De la Camp urges conservatism in the use of exploratory puncture in internal medicine. He advises placing the

needle just below the upper border of fluid transudates rather than near the lower border. The inspection of the acquired material offers therapeutic suggestions. It must not be forgotten that infection of the canal can take place in the act of withdrawing the needle. He cautions against the use of the needle for the purpose of diagnosing focal diseases of the lungs and abdominal organs, especially of the spleen.

ZENTRALBLATT FUER CHIRURGIE.

March 18, 1905.

1. An Easier Performance of Vaginal Hysterectomy, with a Thickened Cervix, By C. LAUENSTEIN.

1. **Vaginal Hysterectomy.**—Lauenstein prefers the abdominal method of hysterectomy for cancer, on account of the better view of the operative field which is thus obtained. Sometimes, however, the cervix is enlarged and thickened, and it is desirable to perform the operation by the vaginal route. He first removes the lower part of the uterus, thus providing a great deal more space; he then removes the remainder of the uterus with the adjacent parts of the broad ligament. The vesicouterine fold of peritonæum is not disturbed until toward the end of the operation. Hemorrhage from the branches of the uterine arteries is controlled as the broad ligaments are removed. Usually but one clamp and one ligature are required.

ZENTRALBLATT FUER GYNAEKOLOGIE.

March 25, 1905.

1. The Poison of Eclampsia, By A. DIENST.
2. A New Perforator, By P. ZWEIFEL.

1. **Eclampsia.**—Dienst regards eclampsia as due to a poisoning of the maternal by the fetal blood. He was able to demonstrate in fifteen placentæ a communication between the fetal and maternal circulation. To evoke eclampsia, the blood of mother and child must bear the relation of that of two different species to each other, this necessitating a communication between their respective circulations. In other words, eclampsia is due to a transfusion of the heterogeneous blood of the child into the blood of the mother through a pervious placenta. Hæmoglobinuria in eclampsia is to be referred to a destruction of red cells and the subsequent strong development of hæmagglutinins and later of hæmolysins in the blood of convalescent eclampsics seems to be related to the hæmoglobinuria. The author further says that women with considerable quantities of agglutinins in the blood are especially prone to eclampsia, as those recovering from chlorosis, scarlatina, diphtheria, tuberculosis, and colds. This would also explain the occasional epidemic character of eclampsia.

April 1, 1905.

1. Ovarian Changes in Hydatid and in Normal Pregnancy, By J. WALLART.
2. Ovarian Changes in Syncytial Tumors and Hydatid Pregnancy, By S. PATELLANI.
3. Intrarenal Tension as a Cause of Eclampsia, By A. MYNLIFF.
2. **Ovarian Changes in Syncytial Tumors.**—Patellani examined the ovaries in sixty-eight

cases of tumors arising from the syncytium and of hydatid pregnancies. In sixty-two of the cases he found changes, representing a hyperproduction of lutein tissue with polycystic degeneration of the corpora lutea, and a displacement of the lutein cells by œdema of the ovarian tissue. The germinal epithelium had more or less disappeared and the number of ovarian follicles diminished.

3. **Intrarenal Tension and Eclampsia.**—Mynlieff says that increased pressure in the ureter leads to venous congestion of the kidney; then, on account of urinary retention and the thickness of the kidney capsule, the intrarenal tension is raised. This is of especial significance in pregnant women, because the blood contains many toxins. In sixty-nine eclampsics, he found the ureter and pelvis of the kidney dilated in thirteen, but he also saw the same condition in twenty-nine out of 164 healthy pregnant women. The author ascribes the eclampsia to the combined mechanical and toxic trauma. He advises decapsulation of the kidney for the treatment of eclampsia.

April 8, 1905.

1. The Blood Forming Organs During Pregnancy and the Puerperium, By F. VARALDO.
2. A Carcinoma of the Ovary with Chorioepitheliomatous Formation, By F. MICHEL.

1. **The Blood Forming Organs.**—Varaldo has made histological studies of the bone marrow, the spleen, the blood, the lungs, the thyroid gland, and the periuterine lymph glands of rabbits and guinea pigs which were killed at various stages of pregnancy and the puerperium. He found a leucocytosis and an increase in young red blood cells, a change which corresponds to a reaction of the lymphoid and myeloid blood forming organs. The individual findings must be looked for in the original; the paper does not lend itself to abstraction.

2. **Carcinoma of the Ovary.**—Michel says that in looking for chorioepitheliomatous tumors in women corresponding to similar findings in the testicle, pregnancy must be absolutely excluded. He describes the case of a young virgin who had a tumor of the ovary. Three years later there was a recurrence and death followed. Histologically, the recurrent tumor gave the picture of a pure chorioepithelioma of the ovary, although the primary tumor was a papillary carcinoma.

FORTSCHRITTE DER MEDIZIN.

April 1, 1905.

1. How Can Pneumonia and Bronchitis Be Avoided After Narcosis? By MÜLLER.
2. Pregnancy Reactions in the Fœtal Organs and Their Involution During the Puerperium, By HALBAN.
3. My Method of Rapid Mechanical Dilatation of the Cervix Uteri During Labor, By BOSSI.
4. Röntgen Rays as a Cause of Cancer, By ALLEN.
2. **Pregnancy Reactions in the Fœtal Organs and Their Involution During the Puerperium.**—Halban, proceeding from the assumption that the pregnancy changes which especially concern the genital apparatus, are the effect of chemical sub-

stances produced during pregnancy, sought to determine whether the supposed poisons in the foetal organism produce the same reaction as in the maternal. His investigations, which were made upon twenty-one fetuses, showed that the changes were analogous, hypertrophy and hyperæmia taking place in the uterus, and hypertrophy in the mamma in the female, while in the male there was hypertrophy of the prostate. The poisonous substances caused leucocytosis, increase of fibrin, and œdema the same as in the mother. The substances which are probably the cause of eclampsia are the secretion of the chorionic epithelium. With the disappearance of this secretion puerperal involution of all the hypertrophied organs in both mother and child occurs, and a regeneration of the organs which may have been affected by the poison.

3. **My Method of Rapid Mechanical Dilatation of the Cervix Uteri During Labor.**—Bossi gives a description of the action of a dilator which has been modified from the original. The changes consist in reducing its weight about one half, in enabling one to spread out its branches upon a level surface, in making it more readily sterilizable, in attaching a lateral screw to the lever arms which permits a test of the resistance of the soft parts, and in lowering the price. Bossi cautions against too rapid dilatation except under conditions that are most urgent. An interval, including several pains, should pass between successive dilations, and the stretching should be done between the pains.

4. **Röntgen Rays as a Cause of Cancer.**—Allen reports three cases in which an epithelial cancer upon the arms was caused by x rays. The first case was in an engineer in Edison's laboratory, whose work was to test the x rays. A year after taking his position an erythema, like that of sunburn, appeared on his hands. Then appeared tumors which healed in one place, but developed inwardly in others. They gradually extended up the arm, and amputation was required, but the patient died. Two other cases occurred in physicians, of one of whom one hand was amputated and part of the other. In the other case the disease rapidly extended to axillary glands so that amputation would have been futile.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

March 5, 1905.

1. The Vasomotor Origin of Bronchial Asthma,
By F. GALDI.
 2. Observations on the Blood in a Case of Chronic Dysentery,
By G. GUYOT.
 3. A Case of Very Severe Tuberculosis, Treated with Hæmoantitoxine,
By M. CECI.
 4. Anthrasol in Therapeutics,
By DOMENICO BRUNO.
 5. Parona's Method for Chronic Tumors of the Spleen in Malaria,
By M. E. GRANDE.
 6. The Use of High Frequency Currents in Ozæna,
By RAOUL HAHN.
1. **Vasomotor Origin of Bronchial Asthma.**—Galdi supports the theory of the vasomotor origin of bronchial asthma, citing an interesting case in which a woman had suffered for years from bron-

chial asthma, and in which a distinct connection between the attacks of dyspnoea and other vasomotor phenomena could be traced. Thus this patient was subject to hyperidrosis, to urticaria, to a sense of prickling in the limbs, œdema, ptialism, swelling of the tongue, and diarrhœa. These signs appeared usually in the intervals between the attacks and disappeared when the attacks set in. Another noteworthy feature in this case was the relation of the paroxysms of bronchial asthma to menstruation. When menstruation set in, the paroxysm ceased. On the other hand, in the presence of severe and repeated paroxysms which came on from time to time menstruation became irregular. The treatment consisted in the use of tepid general sulphur baths, and local irritation about the dorsal region of the spine, to stimulate the vasomotor centres. Tonics were also administered.

2. **Hæmoantitoxine in Severe Case of Tuberculosis.**—Ceci reports good results with the use of hæmoantitoxine in treating a severe case of pulmonary tuberculosis in a woman aged 39 years. According to the author's account, this patient was in a desperate condition, extremely emaciated, with high fever, when recourse was had to hæmoantitoxine, after all other remedies had failed. Hæmoantitoxine was given in doses of a tablespoonful three times daily before meals. After seventy-six days, the night sweats had disappeared; the fever was almost gone, and the patient had gained one kilogramme in flesh. Her general condition was greatly improved. He obtained similar results in other cases of tuberculosis.

3. **Parona's Treatment for Enlarged Spleen in Malaria.**—Grande reports a case of malaria with enormously enlarged spleen in which he used Parona's treatment, viz., the injection of a solution of potassium iodide and iodine. Fifteen injections reduced the spleen three fingers' breadths in the long axis of the organ. In three other cases good results were also obtained with this treatment. In two of these, not only did the splenic tumors disappear, but the fever was also gone, and the general condition of the patient was vastly improved, although quinine had done no good in these chronic cases.

4. **High Frequency Currents in Ozæna.**—Hahn used the high frequency currents by means of a special nasal electrode in the treatment of ozæna. Of all the explanations of the origin of ozæna, there is no single theory that is satisfactory. Probably the disease results from a combination of the proper soil with special pathogenic germs. The most rational method of treatment is to apply bactericidal measures, and at the same time to act not only upon the surface of the mucosa, but upon the submucosa. Bordier and Collet in 1902 applied high frequency currents in the treatment of ozæna, and since then the present author has used this method in seven marked cases of the disease. He used an Oudin resonator with an electrode similar to that used by Bordier and Collet—namely, a metallic rod covered with paraffin or wax, and placed in an insulating han-

dle. The electrode may also be enclosed in a tube of glass, which allows only the tip to project. Care must be taken to apply the effluvia to every part of the affected mucosa. The smaller the sparks, the less irritation and reflex action will there be. No cocaine nor adrenalin was needed in any of these cases before applying the high frequency current, but the patient sneezed a few times after the current was turned on, complained of burning, slight pain, and lachrymation. But these symptoms vanished in two or three minutes if the application was continued. After three minutes the electrode was withdrawn and the patient was asked to blow his nose, when all the crusts usually came away at once. The seance was repeated in from seven to forty-eight hours, and lasted usually about fifteen minutes, although it can be made twice as long without harm. No other treatment, not even irrigation, was used. While the author does not allege absolute cures in his seven cases, the improvement was very marked, indeed, and the mucous membrane in some cases assumed a more normal and more succulent aspect. In all cases the crusts disappeared and the odor was removed, while the subjective symptoms, including the headaches, were almost abolished. He believes that high frequency currents have an antiphlogistic and resolvent action upon the mucosa of the nose in ozæna.

RIFORMA MEDICA.

April 1, 1905.

1. Some Points on the Treatment of Pott's Disease (*To be continued*), By ARTURO CAMPANI.
2. On the Ætiology and Pathogenesis of Cancer, By GIUSEPPE MANISCALCO.
3. Researches on the Metabolism in Chronic Leucæmia (*Concluded*), By FRANCESCO DI GRAZIA.

2. **Ætiology and Pathogenesis of Cancer.**—Maniscalco, in concluding a critical review of the latest researches in this field, inclines towards the traumatic theory of the origin of cancer. He thinks that this explanation is the most plausible yet offered, and that traumatism and repeated irritation are the true causes of cancerous growths. The atypical epithelial productions which are effected experimentally as the result of traumatism or irritation confirm this hypothesis, and the author was able to confirm this experimentally by producing incipient tumors in the stomach of animals. He performed gastroenterostomy in dogs which he killed a few days afterwards. In the stomach of these dogs, in the neighborhood of the newly made pylorus, the epithelial coat had suffered partial losses which were partly replaced by regenerated cells. The new epithelium was composed not only of mucous cells, but also of protoplasmic cells. In the affected glands there was hyperplasia and caryocinesis of the epithelium. On scraping the lining of the stomach in other dogs he produced a series of changes which appeared at first to be regenerative in character, but which in reality constituted a pathological proliferation, inasmuch as the process was complicated by inflammatory changes. The author thinks that a change of a regenerative process in glandular epithelium into a morbid proliferation is produced

by the addition of an inflammatory process. It is in this way that the traumatic origin of cancerous growth may be explained. While he does not assert that he has spoken the last word on this subject, he calls attention to the possibility of further studying this question experimentally on the lines indicated, and of further determining the relationship between cancer and regenerative processes complicated by inflammatory changes.

3. **Metabolism in Chronic Leucæmia.**—Di Grazia found that the only feature of note which the urine of his two patients had in common was that the amount of uric acid and of alloxur bases eliminated was slightly increased in both. Otherwise the urines differed in all respects. In the first patient, who was in fairly good condition, the nitrogenous metabolism was not markedly affected. The amount of urea eliminated in proportion to the total nitrogen was normal. In the second patient, whose condition was poor, there was a general lowering of the urea-nitrogen coefficient, and a marked increase in monoamidic nitrogen. The elimination of phosphorus was normal, and parallel to that of nitrogen in the first patient, while in the second it was low, but relatively high as compared to the total nitrogen. The elimination of hydrochloric acid and of sulphuric acid did not present any noteworthy features. The author concludes from his exhaustive study of this subject that the metabolism of a leucæmic may vary within the widest limits. In some cases the nitrogen is found in equilibrium, in others it is eliminated too rapidly; in still others it is partly retained. The uric acid may reach the enormous figure of five grammes per day, or, on the other hand, it may be below the normal. The same is true of the alloxur bases, the ammonium, and the salts. Further researches are necessary to determine whether these variations are connected with any special clinical varieties of the disease.

ROUSSKY VRATCH.

March 26, 1905.

1. A Case of Extrauterine Pregnancy, with Full Term Fœtus, By P. V. MIKHINE.
2. Indications for the Radical Cure of Hernia by Bassini's and Kocher's Methods, By P. A. BARATYNSKI.
3. The Action of Bitters Upon the Secretory Function of the Gastric Glands, By N. D. STARZESKO.
4. A Case of Extrauterine Tubal Pregnancy and Cancer of the Cervix, By N. I. POKROVSKI.
5. First Aid in Accidents (*Concluded*), By D. P. NIKOLSKI.

1. **Extrauterine Fœtus at Term.**—Mikhine reports a case of extrauterine pregnancy, in which the fœtus was carried to term, and the live child was removed by abdominal section. The patient had had three normal labors previously. She developed the usual signs of pregnancy, and in addition complained of an increasing dull pain and sense of weight, of disturbances of urination and defecation. On examination, the uterus was felt pressed against the pubis, and the anterior vaginal wall was pushed forward. The incision in the linea alba corresponded to the edge of the pla-

centa, and the latter bled freely, but the foetus was successfully removed from its membranes and the remainder of the ovum was dried by means of gauze tampons, its edges sewn to the edges of the wound, and its cavity packed loosely with gauze strips. The uterus was found enlarged, to about three and a half months, and its appendages were perfectly normal, not having taken the least part in the formation of the sac. The patient made an uneventful recovery.

2. Methods of Operation in Hernia.—Baratynski says that Kocher's method is best adapted for cases of inguinal hernia with slight anatomical changes in the inguinal canal, *i. e.*, a narrowing. In hernias with moderately marked anatomical changes the choice between Bassini's and Kocher's methods depends on the degree of mobility of the peritonæum and on the separation of the deep layers of the abdominal muscles from Poupart's ligament. If the peritoneal mobility is marked, Kocher's method is indicated, while if the deep muscles are widely separated from Poupart's ligament, it is best to use Bassini's method. Inguinal hernias with marked anatomical changes in the canal—that is to say, with a widely distended straight or oblique inguinal canal—require Bassini's method.

3. Action of Bitters on the Stomach.—Starzhesko found experimentally that bitters increase the psychical stream of gastric secretion. It remains to be decided by further investigations whether this increase is the result of a simple reflex, or of a complicated nervous mechanism, involving the cerebral cortex. The practical deductions from this research are summed up as follows by the author: Small amounts of bitters must always be used, as the administration of large doses has the opposite effect from that desired, and the repeated use of large amounts may produce a permanent hyosecretion in the stomach. Bitters must always be administered in such a form as to excite the nerves of taste, while the drugs are taken. In other words, the use of bitters in the form of pills and wafers or capsules is not rational. Bitters must always be given before eating, and best ten minutes or fifteen minutes before.

9. Rheumatism and Other Affections of the Joints,

By CHARLES R. GRANDY.

10. Immunity. Chapter XIV. Concluded.

1. Paresis.—Dana presents what, to him, is convincing evidence that paresis, in its very earliest stages, in that stage which may be called one of "præparesis," is a disease that sometimes can be arrested. This arrest may be permanent, and may be attended with so little mental defect that one may call the patient practically cured. The author's argument is along three lines: (1) Analogy. Paresis like tabes is, in a large proportion of cases, a parasymphilitic disease. Their pathology is essentially similar. It has been established quite clearly that tabes can be arrested in its early stage and that patients may live for twenty or thirty years and exhibit practically no changes in their symptoms. If this is true of locomotor ataxia it should be true of paresis which is essentially the same disease in a different location. (2) There is no reason why paresis should not be curable. We are able to arrest degenerative processes in other parts of the nervous system; we arrest degenerative processes, or we see them arrested, in the kidneys, in the liver and in other organs. Given a vigorous constitution poisoned with disease, it may well be that when it is put under the best possible conditions for fighting this poison, when its known antidote has been administered with heroic thoroughness, we might expect that the tendency of the tissue to die may cease. (3) Clinical evidence. Experience shows that cases which exhibit all the clinical signs and symptoms of early paresis do get well. It is begging the question to say that all those that do get well are not paretics. Seven cases are reported which exhibited the early signs of paresis and which recovered. The author admits that this part of his argument is the weakest, and that the patients he has classed as paretics others will hold were not paretics, but sufferers from brain syphilis.

2. Pneumatocoele of the Cranium.—McArthur reports one personal case of this rare condition and tabulates a synopsis of thirty-three cases he has found in the literature. The conclusions reached by Costes, of Bordeaux, in 1859, regarding this affection hold good to-day. They are (1) Pneumatocoeles are very rare. (2) They always depend on perforations of the bony walls. (3) They are always tympanitic. (4) They are more or less reducible by pressure. (5) They can take their origin from the mastoid or frontal sinuses only. (6) They are of very slow and indolent formation. (7) They are never dangerous except from complications (infections).

4. Tuberculous Deposits in the Tonsils.—Wood, from recorded clinical data and from experiment, has attempted to establish the relationship between the tonsils and tuberculosis. His conclusions are: The tonsillar tissue of the throat, because of its peculiar anatomic construction and its topographical relations, is more liable to become infected by tuberculosis than any other part of the upper respiratory tract. In nearly all cases

of advanced pulmonary phthisis the faucial tonsils become inoculated. In about 5 per cent. of hypertrophied pharyngeal tonsils some form of primary tuberculosis will be found. Primary infection of the faucial tonsil is a rarer condition. Tuberculous adenitis in the cervical lymphatics develops in the majority of cases from infection originating sometimes in the faucial tonsils, but more frequently in the pharyngeal tonsil. The tubercle bacillus is probably unable to pass through the tonsils without having first overcome the vital resistance of the tonsillar tissue. The danger of systemic or pulmonic infection resulting from a tuberculous lesion in the tonsillar tissues of the throat is about equal to that of tuberculosis of the cervical lymphatics. The lesion to be expected as a resultant infection from the broken down glands of the neck is a miliary tuberculosis of the lungs. Further than this possibility, tuberculosis of the lymph glands of the neck is no more dangerous than a localized tuberculous lesion in any other portion of the body. The tonsils are more resistant to the action of bacterial toxins than ordinary lymphoid tissue.

9. Rheumatism.—Grandy reviews a number of affections, articular as well as non-articular, which are often confused with rheumatism and treated as such. This, of course, is not as it should be, and the moral of the paper is that all patients who suffer with pain in or about the joints should not forthwith be put on salicylates and a special diet.

BOSTON MEDICAL AND SURGICAL JOURNAL.

May 4, 1905.

1. Certain Aspects of the Differential Diagnosis Between Epilepsy and Hysteria,
By JAMES J. PUTNAM and GEORGE A. WATERMAN.
2. Subacute Perforation of the Stomach, with Report of Three Cases,
By F. B. LUND.
3. Senile Epilepsy,
By G. KIRBY COLLIER.

1. Epilepsy and Hysteria.—Putnam and Waterman call attention to the great difficulty that may occasionally arise in attempting to differentiate epilepsy from hysteria. A number of cases are reported in order to illustrate the methods of investigation by which the authors believe that a correct conclusion may generally be reached. They advise that every neurological staff of dispensary and outpatient services should embrace one or more members skilled in psychopathical researches by whom all doubtful cases should from time to time be reviewed in order that no injustice be done to the patients.

2. Perforation of the Stomach.—Lund concludes: (1) The symptoms of subacute perforation of the stomach are similar to those of acute perforation, with the important exception that they are less violent and are not followed by collapse or by the development of general peritonitis. (2) The location of the pain and tenderness depends upon the location of the ulcer and varies with it. (3) The treatment should be, if possible, posterior gastroenterostomy without breaking up the protective adhesions.

3. Senile Epilepsy.—Collier advances the tentative view that epilepsy may be due to old age. His argument is in two parts: the first concerns itself with the general effects of senility, the second with the frequency of senile epilepsy. At the Craig Colony there have been 21 cases of epilepsy whose first manifestations occurred between the ages of forty-five and ninety. Of these seven were probably due to senility.

MEDICAL RECORD.

May 6, 1905.

1. System and Expedition in Office Practice. Office Plans and Details,
By ROBERT L. DICKINSON.
2. The Present Limitations of Serum Therapy in the Treatment of the Infectious Diseases, By HENRY W. BERG.
3. The Present Status of Röntgen Ray Therapy,
By RUSSELL H. BOGGS.
4. Rectal Abscess Containing Gonococci Without Any Accompanying Gonorrhœa,
By F. R. STURGIS.
5. The Cause of Cerebrospinal Meningitis,
By STEPHEN J. MAHER.
6. Cactus Grandiflorus,
By FINLEY ELLINGWOOD.

1. Office Plans.—Dickinson's paper will be useful mainly to those physicians who own their own house or who have leased for a long term of years. There are many suggestions concerning office routine which are generally applicable. Physicians intending to remodel their offices would do well to look the paper over.

2. Serum Therapy.—Berg deprecates the present tendency to employ sera when they are contraindicated by all known bacteriological facts; such attempts, for instance, as those recently, made to cure epidemic cerebrospinal meningitis by means of injections of diphtheria antitoxine. The present limitations of serum therapy can only be understood by reviewing the properties of the principal pathogenic bacteria. (1) Those bacteria which produce free toxins (diphtheria, tetanus, etc.) can have their effects partly neutralized by suitable antitoxines. (2) Some bacteria secrete little or no free toxine (pneumococcus, typhoid bacillus, etc.), but they contain an endotoxin which is partly liberated on the death of the organism. (3) There is a group of bacteria which produce no toxins and contain endotoxins of only very feeble powers (the tubercle bacillus). From this it will be seen that the problem of producing curative sera is not a simple one, and that to use specific sera in any disease except the one for which it was produced is irrational. The author explains at length why bacteriolytic sera have mostly failed.

4. Rectal Abscess.—Sturgis reports the case of a man who developed a rectal abscess, due to the gonococcus, six or seven years after a cured gonorrhœa. Pederasty was apparently excluded.

5. Cerebrospinal Meningitis.—Maher inoculated some culture tubes with pus from a case of cerebrospinal meningitis. In due course of time he observed apparently different forms of microorganisms in several of the tubes. As a result of these observations he is impelled to make the following observation: "He would be daring who would generalize on so large a subject from his

work on one case, but may I be permitted to conclude by saying that my findings seem to show that the diplococcus of Weichselbaum is only one phase in the life cycle of an organism, which at times is larger and rod shaped, at others small and of the shape of the pneumonia diplococcus, and probably at others of yeast shape."

MEDICAL NEWS.

May 6, 1905

1. Railway Spine, By EDWARD B. ANGELL.
2. Treatment of Non-Malignant Diseases by the Röntgen Ray, By RUSSELL H. BOGGS.
3. To What Extent are Cycloplegics Necessary in Determining the Refraction of the Eye and in the Prescribing of Lenses, By FRANK VAN FLEET.
4. Nasal Conditions Dependent Upon the Generative Organs, By JUSTUS SINEXON.
5. Septic Thrombosis of the Femoral Vein, Following Influenza, By D. F. TALLEY.
6. Sporadic Cretinism. Observations Based on Fourteen Personal Cases, By E. MATHER SILL.

1. **Railway Spine.**—Angell reviews the history of railway spine and reports several cases briefly. He concludes: "Railway Spine" is a convenient and picturesque term which has hypnotized juries, even as the shock has hypnotized the plaintiff. It is dramatic, but not accurate. The damage done is not to the spine or spinal cord, but to the mind. It is a psychical disorder not a physical one, although it has a physical expression in its symptomatology.

2. **The Röntgen Ray.**—Boggs lays much stress on the importance of technics in x ray work. The non-malignant conditions which are most benefited by this mode of treatment are: (1) Acne and many other skin diseases; lupus; certain tuberculous glands; Hodgkin's disease, and selected cases of goitre.

4. **The Nose and the Generative Organs.**—Sinexon concludes: (1) That turgescence of the nasal mucous membrane always occurs during the procreative act. (2) That there also exists a marked degree of hyperæsthesia of the nasal mucous membrane at such time. (3) That a more or less marked periodical engorgement of the nasal mucosa occurs in females coincident with menstruation. (4) That this same engorgement also occurs periodically during pregnancy, demonstrating that it is not dependent upon the menstrual flow. (5) That operations which destroy the functions of the generative organs cause the nares to return to the state which existed prior to the advent of puberty. (6) That in lower animals sexual excitement is always accompanied by occlusion of the nares. (7) That this engorgement in the human family may result in epistaxis or hydrorrhœa. (8) That the continued overstimulation of the nasal mucous membrane from sexual perversion results in a relaxation of the same through vasomotor paresis. (9) That the long-continued hypernutrition from frequent or inordinate congestion will in time produce permanent tissue changes either of hyperplasia or atrophía. (10) That these conditions are in no way dependent upon hysteria or neurasthenia.

5. **Septic Thrombosis.**—Talley reports one personal case of septic thrombosis due to influenza and two cases which he has found in the literature. Aside from the histories of the cases the greater part of the paper consists of a quotation from Finkler's article on the subject in the Twentieth Century Practice of Medicine.

AMERICAN MEDICINE.

May 6, 1905.

1. The Methods of Inducing Labor, By B. C. HIRST.
2. Adulteration of Drugs, By H. W. WILEY.
3. The Combined Operation of Arthrodesis and Transplantation of the Tendon of the Extensor Proprius Hallucis for the Relief of Flatfoot, By H. AUGUSTUS WILSON and ROSS V. PATTERSON.
4. The Diet in Typhoid Fever, By JOHN BENJAMIN NICHOLS.
5. Remarks on the Causation and Diagnosis of Hepatic Cirrhosis, By JAMES K. CROOK.
6. Benign Strictures of the Œsophagus: Report of Cases, By C. D. SPIVAK.
7. The Gynecologist and the General Surgeon: Their Respective Fields, By BROOKS H. WELLS.
8. The Most Eminent American Physician of European Birth, By A. JACOBI.

1. **Induction of Labor.**—Hirst asserts that the method of inducing labor by means of bougies gives the best results. He does not give his total experience, but bases his paper on the statistics of the University of Pennsylvania Hospital. They are: Labor induced by bougies alone, 174; by bags alone, 23; by bougies and bags, 11; by bougies followed by Bossi's dilator, 7; by bougies followed by vaginal hysterotomy (misnamed vaginal Cæsarean section), 2; making a total of 217 patients operated on. These figures are carefully analyzed and bear out the author's contention.

3. **Flatfoot.**—Wilson and Patterson advocate the following method for the treatment of suitable cases of flatfoot. The astragaloscaphoid articulation is destroyed by means of a chisel or bone forceps. A hole is drilled through the scaphoid bone, and through this hole is passed the severed tendon of the extensor proprius hallucis, whose cut proximal end is sutured to the periosteum on the plantar side of the scaphoid. The after treatment is of considerable importance.

4. **The Diet in Typhoid.**—Nichols in a rather elaborate paper advocates a more liberal diet in typhoid fever. The greater part of the paper is taken up with theory. It concludes with a summary of the experiences of various practitioners who have recently advocated feeding typhoid patients more liberally.

LANCET.

April 22, 1905.

1. On the Dissemination of Mammary Carcinoma. (*Hunterian Lectures, III*), By W. S. HANDLEY.
2. Some Considerations on the Nature of Diabetes Mellitus. (*Goulstonian Lectures, III*), By W. C. BOSANQUET.
3. Gallstones and Cancer, By G. R. SLADE.

4. Three Cases Illustrating the Condition of the Small Intestine Some Years After Extensive Enterectomies, By A. E. J. BARKER.
5. A Further Note on the Relation Between Various Atmospheric Conditions and the Occurrence of Cerebral Hæmorrhage, By J. W. RUSSELL.
6. Plague in Cats, By W. HUNTER.
7. Suppurative Periostritis Following Typhoid Fever, By W. H. BATTLE and L. S. DUDGEON.
8. A Cerebrospinal Manometer, By F. C. EVE.

1. **Cancer of the Breast.**—Handley, in his third Hunterian lecture, discusses the origin of metastases of cancer of the breast found in the breast. There are few forms of carcinoma in which visceral deposits are more frequently found. Of 329 cases metastases occurred in 77 per cent. The great frequency of visceral metastases is mainly owing to the extension of cancerous permeation along the five anastomoses, which piercing the parietes, connect the lymphatic plexus of the deep fascia with the subendothelial lymphatic plexuses of the pleura and peritonæum and with the mediastinal and portal glands. The dominant factor is the escape of cancer cells into the serous cavities. In conclusion, the author draws the following practical conclusions: If, when it transgresses the limits of the breast, cancer spreads primarily in the deep fascia, the main operative aim next, of course, to complete removal of the breast and of the axillary glands, should be the removal of as wide an area as possible of the deep fascia. And if the mode of fascial extension is by centrifugal continuous permeation, the area affected is roughly a circle and the area of fascia removed should also be circular with its centre at the point of origin of the original neoplasm. Hitherto too much attention has been paid to the pectoral fascia and axillary glands, with consequent inadequate excision of the deep fascia in a downward direction over the upper part of the abdomen. In order to prevent epigastric invasion the usual incision should be prolonged downwards over the linea alba for about two inches, the flaps undermined, and the fascia excised as far down as two inches below the ensiform cartilage or even lower. This step does not increase the shock of the operation. Excision of the overlying skin and of the underlying muscle must be free, but need not be so extensive as that of the fascia. Removal of the deep fascia is carried out more thoroughly in England than elsewhere, but even there it is deficient in the direction of the epigastrium. Local and intrathoracic recurrence after the operation for cancer of the breast is becoming more and more infrequent, but purely abdominal recurrence is increasing in relative frequency. The author concludes by expressing the firm belief that a recognition of the danger of epigastric invasion and the adoption of precise means for its prevention will bring about a further appreciable reduction in the mortality from mammary carcinoma.

2. **Diabetes.**—Bosanquet, in his third of the Goulstonian lectures, sums up his views regarding the nature of diabetes: 1. Excess of sugar in the blood, the condition precedent of glycosuria,

may be caused by overproduction of sugar in the system or by diminished use or excretion. And the evidence of overproduction is convincing. 2. Overproduction may depend upon some digestive irregularity, or upon manufacture of sugar from the tissues of the body. This last obtains in diabetes mellitus alone—i. e., autolytic formation of sugar is the characteristic feature of diabetes. 3. It is probably present all through the disease, but in the early stages its absence may be due to a certain power of the body of utilizing sugar in its nutritive processes. 4. It is very probable that the pancreas is diseased in all cases of diabetes mellitus. The function of the pancreas which is in abeyance in diabetes is normally performed by certain special groups of cells known as the islands of Langerhans, which are distinct from the ordinary secreting cells of the gland, but which are not unprobably formed from the acini. The special lesion of these islands is hyaline degenerations. 5. The action of the pancreas is probably exerted in the direction of counteracting a poison which in some way causes accumulation of sugar in the blood. 6. It is theoretically possible that sugar may be derived from fat; this is borne out by the fact that a serious disturbance of the adipose tissue exists in diabetes. 7. Glycosuria as opposed to diabetes may be due to mere excess of sugar poured into the blood from the alimentary canal in excess of what the system is capable of assimilating; or it may be due to causes acting analogously to Bernard's diabetic puncture, and leading to a discharge of sugar by the liver from its stores of glycogen. If these views are correct it follows that in its earliest stages the diabetic process may constitute rather a predisposing cause of glycosuria than the actual cause of the phenomenon, since the breaking down of the tissue cells into sugar is at first not more than sufficient to saturate the sugar assimilating powers of the system. At this stage a slight increase of saccharine food will produce glycosuria. Similarly a slight nervous shock, liberating only a comparatively small quantity of glycogen from the liver, may be enough to cause the appearance of sugar in the urine, and so be thought the cause of diabetes. So that diabetes might be defined as an increased internal dissociation of tissue (possibly fat) into sugar, caused by a toxic substance which is produced in the course of normal metabolism and which is normally neutralized by the pancreas. The prognosis of any case depends more upon the degree of acid intoxication existing than upon the percentage of sugar in the blood or urine.

3. **Gallstones and Cancer.**—Slade has studied the relation between gallstones and carcinoma of the gall bladder, and reaches the following conclusions: 1. The association between carcinoma of the gall bladder and gallstones is very close. 2. Gallstones may be looked upon as the terminating cause of cancer of the gall bladder. 3. Thickening of the wall of the gall bladder is presumptive evidence of carcinomatous change. 4. Cholecystectomy should be performed whenever possible if any thickening of the wall of the gall bladder be found at the time of operation.

4. Conditions Following Enterectomy.—Barker reports a group of cases in which enterectomy had been performed for intestinal obstruction. Later the abdomen was opened for another cause, and though the obstruction had occurred some years before, it was interesting to observe that though the communication between the two portions of the bowel was perfect and as wide as possible, the afferent or proximal portion still showed unmistakable signs that it had not yet recovered its former tone as contrasted with the efferent or distal portion which was normal.

5. Cerebral Hæmorrhage.—Russell's observations seem to establish that actual height of barometric pressure, temperature, or wind pressure exercises no influence in determining the onset of attack of cerebral hæmorrhage.

6. Plague in Cats.—W. Hunter's conclusions as to the occurrence of plague in cats, are as follows: 1. Cats suffer from plague. 2. The disease may be acute or chronic. 3. The type of the disease is septicæmic. 4. These animals may occasionally play a part in the dissemination of plague. 5. In plague infected districts possible plague infection in cats is of great importance from a domestic point of view. 6. In plague infected areas cats probably become infected through plague rats and mice which they devour as food.

8. Lumbar Puncture.—Eve describes an apparatus by which the pressure of the cerebrospinal fluid can be measured when lumbar puncture is performed. A summary of his observations is as follows: 1. The therapeutic effect of lumbar puncture is of considerable value, and its effects are produced as follows: (a) excessive tension is reduced; (b) the brain is washed by fresh fluid secreted in place of that withdrawn; (c) a temporary cerebral hyperæmia is produced by the blood vessels dilating to take the room of the fluid withdrawn until a new supply is secreted, or, conversely, a cerebral anæmia due to excessive intracranial pressure may be arrested; and (d) a substantial change of cerebral environment is produced, of which Nature may sometimes be able to take advantage. 2. Lumbar puncture has been performed about sixty times with the author's instrument without any bad effects. 3. Valuable diagnostic information is often afforded: (a) Pink fluid indicates cerebral hæmorrhage, fractured skull (with injury to the dura mater) or severe superficial cerebral laceration (with pia mater); (b) a faint "spider's web" clot after standing several hours points strongly to meningitis; (c) cytological, bacteriological, or inoculation experiments may give the diagnosis; and (d) occlusion of the cerebral from the spinal cavities may be diagnosticated and this may localize a subtentorial tumor. 4. In apoplexy, lumbar puncture is conceivably justifiable when the pressure is found to be very high, provided that the pressure is slowly reduced to half its value, not too soon after the occurrence of the hæmorrhage. But such treatment would certainly be dangerous without a manometer. 5. There may exist a disease of very high pressure in the cerebrospinal cavity analogous to glaucoma in the ocular cavity. 6. Lum-

bar puncture is said to be dangerous in cerebral tumor. 7. Very good results have followed the use of lumbar puncture in cases of fractured base, concussion, posttraumatic cerebral condition, very severe chorea, uræmic coma, optic neuritis, ataxia, and tuberculous meningitis.

BRITISH MEDICAL JOURNAL.

April 22, 1905.

1. Remarks on the Determination of Arterial Blood Pressure in Clinical Practice, By C. J. MARTIN.
2. A Case Simulating Intracranial Tumor in Which Recovery was Associated with Persistent Cerebrospinal Rhinorrhœa, By T. R. GLYNN and E. E. GLYNN.
3. Arthritis Deformans and Its Allies, By B. ABRAHAM'S.
4. The Medical Treatment of Insanity, By R. JONES.
5. An Inquiry Into the Existence of Typhoid Fever in Bermuda, By L. KILROY and F. W. HOOPER.
6. The Corneal Reflex in Anæsthesia, By L. K. THOMAS.

1. Blood Pressure.—Martin discusses the various methods of determining arterial blood pressure, and describes a simple apparatus devised by himself.

3. Arthritis Deformans.—Abrahams discusses the clinical features of the various affections ordinarily grouped under the name of rheumatoid arthritis. These conditions, arranged chronologically according to the age of the patient, are (a) the children's disease, as described by Still; (b) the acute process occurring in young women; (c) the familiar multiarticular affection of middle aged women; and (d) the equally well known chronic malady of the aged. Still's disease is undoubtedly an infective process, and is usually associated with enlargement of the spleen and lymphatic glands. It is essentially chronic, is more prevalent in boys, and attacks the fingers very late. The second disease is acute, occurs only in girls, and usually commences in the fingers. Pathologically each is a synovitis with only secondary changes in the cartilages. The fourth form of the disease, which occurs at the other extreme of the scale of life, is really a senile osteoarthritis. It is primarily a degenerative process, consisting in fibrillation, breaking up and wearing away of the joint cartilage. The affection is so little inflammatory that it can hardly be called osteoarthritis. Further distinctive features are the absence of anæmia and of nervous symptoms, and the fact that it usually attacks the large joints, especially the hip. Having dealt with these affections of the extremes of life, the author considers true arthritis deformans, acute and chronic; while both these forms are distinct from rheumatism, it is not yet certain that they are distinct from each other. The acute disease is often terribly rapid in its course, but not always. Many joints are affected at about the same time, the proximal interphalangeal, and temporomaxillary being conspicuous among these. The brunt of the chronic form falls upon the metacarpophalangeal joints and the knees. But it is possible that this difference in distribution between the acute and chronic conditions may be one of degree only. No importance is attached to the fusiform swellings upon the interphalan-

geal joints in the acute affection. The inflammatory changes in acute arthritis deformans are primarily and mainly in the synovial membrane; the cartilages are only damaged secondarily, and the only change in the bones is the marked thinning of their ends. The chief features in the chronic form are degenerative changes in the cartilage, involving fibrillation, patches of softening, and hyperplasia. The author suggests that these acute and chronic types are the expressions merely of a similar process attacking joints at different ages. In many cases of the chronic form, there is profound involvement of the nervous system, but the author does not regard it as a nervous disease. In the acute form the nervous system is but little affected. Ordinary arthritis deformans may pass into the senile form, but the latter is often due to other ætiological agencies, in particular old age, as the causes of degeneration.

6. Corneal Reflex.—Thomas agrees with Gardner that for safety in the use of anæsthetics, the air way must be kept clear, but not as to the corneal reflex. He holds that there is, other things being equal, a much greater interval of safety between the corneal reflex and the failure of respiration and heart than is generally admitted. Further, the reaction to corneal stimulation varies enormously in different individuals; so that the corneal reflex cannot be depended upon as a guide in the administration of anæsthetics in cases requiring complete muscular relaxation, especially in abdominal and hæmorrhoidal operations, in which moderate secondary dilatation of the pupil, while keeping a careful watch on the respiration and pulse, is the best guide to complete success.

Letters to the Editor.

THE CLINICAL THERMOMETER.

65 FRENCH BROAD AVENUE,
ASHEVILLE, N. C., April 24, 1905.

To the Editor,

Sir: I have recently had a rather interesting experience in regard to the accuracy of clinical thermometers, of which matter you have lately spoken editorially, so I thought it might be of interest to give you the facts.

I have many patients who need to take their temperatures, and I have always been particular that they should use a clinical thermometer which was as accurate as possible and have had them get thermometers of a well known English make, since I felt the results were apt to be more accurate. In the last year, however, I noticed that the maker, instead of supplying Kew certificates with his thermometers, was certifying them himself, and since I also noticed that all the certificates showed perfect thermometers with the zero error at each of the four usual points, I felt that the reliability of the readings was really thrown in question by such, I may say, impossible perfection. I therefore had the druggist who gets these thermometers for me send six dozen, all of which had perfect certificates from the maker, to the Government Bureau of Standards in Washington.

As every one is aware, the bureau rejects as imperfect all thermometers with an error of four tenths of a degree or more. Of the six dozen thermometers, one dozen, the druggist informs me, were rejected for such error. Of the five dozen others, there were none with perfect certificates and only three with an error of minus one tenth of a degree at each of the four readings. Now, I do not blame the maker for not producing an impossibly perfect thermometer, but I do blame him, since he found out the desire of an ignorant public for perfect certificates, for yielding to this want and giving certificates which scientific test has proved to be unreliable. I do not doubt the excellence of his thermometers, and an error of from one to three tenths of a degree, even in incipient tuberculosis, where small variations are of great importance, is not a matter that need have worried us, but the whole affairs bears out your remarks in recent numbers of your journal and shows the necessity of a government, Yale, or Kew certificate with any thermometer on which we are to rely, and when one thinks how important are the conclusions to be drawn, it is evident that the makers must be awakened to their responsibility in this matter.

CHARLES L. MINOR.

OPERATIONS FOR PHIMOSIS.

50 VANSITTART AVENUE,
WOODSTOCK, ONT., April 24, 1905.

To the Editor,

Sir: I have read with much pleasure the article in the April 8th number by Dr. J. M. White, of Mississippi, upon an operation for phimosis and have been much pleased with his explanation of a new procedure for that troublesome little defect.

However, what I wish to protest against is the doctor's tacit admission that an operation of that kind means the loss of a portion of the foreskin. I, for one, strenuously oppose the method employed by surgeons in nearly all cases, i. e., cutting off a portion of the foreskin on general principles, as being wrong in principle, cruel, and quite unnecessary. I have been guilty in the past of the same error, and have been sorry when I beheld later on a permanently denuded glans.

I have, for the last five years, resorted to the following method: With a small forceps inserted into the end of the contracted foreskin, I dilate the part quite forcibly, being careful not to produce a tear, until the skin can be forced back past the glans.

The mucous membrane being usually firmly or partially adherent, I strip this back so as to completely expose the glans. I then draw the foreskin forward and dilate again; then, after cleansing, I anoint freely with vaseline and leave orders for this to be repeated each morning, and if not perfectly satisfactory to report. The daily retraction and anointing prevent adhesions forming again until healing takes place.

The only exception is in very rare cases, in which the foreskin is extremely long, when, of course, a portion will require removal. In the last five years I have not resorted to the knife once, and complete recovery has occurred in every case. No anæsthetic is used, as the operation occupies but two or three minutes.

A. T. RICE.

MERIDIAN, MISS., April 12, 1905.

To the Editor.

Sir: I have received several letters relative to my operation for phimosis, described in your journal for April 8th. The writers wish to try the *opelation*, and a few request me to describe it more plainly. The dorsal cut is made with scissors. Then the prepuce is stretched or held taut laterally with fingers or forceps. Then the small sized continuous catgut suture is inserted, beginning at the dorsal cut and ending at that point. Then the suture is tide in a bowknot (temporarily), now the prepuce is cut in front of the suture all around with scissors. The bowknot is now untied and a surgeon's knot is tied—not too tight—or the suture can be left untied till the prepuce is cut off. I have a compound stearate of zinc powder with lycopodium that I use as a dressing, which I much prefer to iodoform. Any dressing that is applied should be loose.

J. M. WHITE.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, March 2, 1905.

The President, Dr. RICHARD C. NORRIS, in the chair.

The Induction of Labor.—Dr. HIRST gave the following statistics, mainly from the University Hospital: Though they did not represent his total experience, the number was sufficient to draw conclusions from, and the omitted cases would not materially alter the percentages. Labor induced by bougies alone, 174; by bags alone, 23; by bougies and bags, 11; by bougies followed by Bossi's dilator, 6; by bougies followed by vaginal hysterectomy, 2; making a total of 216 patients operated on. He gave the following statistical review of the cases and the results:

Induced Labor by Bougies Alone, 174.—The child was born in less than six hours after the introduction of the bougies in eight cases; between six and twelve hours in twenty-three; between twelve and eighteen hours in thirty-three; between eighteen and twenty-four hours in fifteen; between twenty-four and thirty hours in eleven; between thirty and thirty-six hours in twenty-three; between thirty-six and forty-two hours in eleven; between forty-two and sixty hours in twelve, and in more than sixty hours in two, the longest time recorded being sixty-two hours. In thirty-six cases the time was not recorded. In 81 per cent. of 133 cases, therefore, the child was born in less than thirty-six hours from the time the bougies were introduced.

Induced Labor by Bags Alone, 23.—The child was born in less than six hours after the insertion of the bags in two cases; between six and twelve hours in three; between twelve and eighteen hours in three; between eighteen and twenty-four hours in seven; between thirty-six and forty-two hours in one; between forty-two and sixty hours in two; over sixty hours in one. The longest time recorded was ninety-one hours. In five cases the time was not noted. The delivery was accom-

plished in less than thirty-six hours in 83 per cent.

In the labors induced by bougies and bags, eleven in number, the time required was considerably over twenty-four hours in all, because much time was allowed the bougies before the bags were used. In one of these cases ninety-six hours were required, and even then, in spite of the fact that the full sized Champetier de Ribes bag passed spontaneously out of the cervix, there were no pains and the fœtus was extracted from the uterus by its foot.

In the cases in which Bossi's dilator was used or vaginal hysterectomy was performed delivery was concluded naturally and promptly.

Dr. Hirst said that the physician desired for the patient the method that would cause the minimum of discomfort and risk, and for himself he desired a method that would give the least trouble and take the least time. The bougie method, in his experience, best met these requirements. In private practice, before leaving his office the physician put two bougies, size, 17 French, into a long glass tube filled with water, into which a mercuric chloride tablet was dropped, and the tube corked. By the time he arrived at the patient's house, the bougies were sterile. Before the bougies were put in, one or two fingers should be inserted through the cervical canal and swept around the lower uterine segment to separate the membranes. A small tampon of iodoform gauze was placed in the vagina after the bougies were inserted. The physician was notified when the pains became strong and active. He made no examination, and did not remove the vaginal packing or the bougies till expulsive pains began. He simply devoted the time and attention required in an ordinary labor case, plus about fifteen minutes or less for the insertion of the bougies. The patient had to endure the usual suffering of an ordinary labor, plus the scrubbing of the vagina. She did not feel the introduction of the bougies. In more than four fifths of the cases she was delivered easily after a labor of average length. He thought any more complicated or active treatment to bring on the labor unnecessary. In many instances patients responded extraordinarily well to this simple plan. In sixty-four out of 138 cases the child was born in less than eighteen hours from the time the bougies were inserted.

In contrasting the bag method with that of the bougies, Dr. Hirst said the bags must be boiled; their insertion was usually painful; and, if a large one was used, preliminary instrumental dilatation of the cervix was required, for which the patient ought to be anesthetized. After the insertion it was customary to have the nurse pull on the tube attached to the bag every ten or fifteen minutes; this, with the pressure of a large foreign body in the lower uterine segment, added to the pains of labor. The physician usually had to make frequent examinations to be sure that the bag had not been expelled from the uterus and to detect the degree of inflation of the os, thus increasing the risk of infection. The bags did not remain sterile; the Voorhees bags, commonly used in America, quickly became foul. In some of his cases the nurse had pulled the bag out prematurely or had pulled the tubing off the bag, necessitat-

ing a reinsertion; and in one case a head presentation had been converted into a shoulder presentation by the largest sized Voorhees bag. In about a fifth of the cases, or in about the same proportion as with the bougies, delivery was not secured in thirty-six hours, and something else had to be done. Thus, the question arose of how to manage an induced labor if the bougies or bags failed. Dr. Hirst's present preference was to insert two bougies and wait twenty-four hours; if there were no labor pains by that time, there was at least always a marked softening and elasticity of the cervix. The patient might then be anesthetized and placed on an operating table. With Bossi's dilator the cervical canal was dilated slowly to 6 or 7 cm. Up to this point there was no danger of injuring the cervix. A forceps was then applied and the child extracted, the whole process taking about thirty-five minutes. He had induced labor by this plan six times. The woman suffered nothing at all in her labor. She did not feel labor pains and knew nothing about the delivery. If there was a moderate laceration of the cervix or pelvic floor, the injuries were repaired in the puerperium, and there were no permanent ill consequences. He thought there was no reason for the prejudice against Bossi's dilator exhibited frequently by those who had had no experience with it. He had used the instrument altogether twenty-five times, nineteen times for accouchement forcé. The only serious lacerations of the cervix had occurred in women delivered in less than twelve minutes. At first the instrument was used in this way for desperate cases of eclampsia, and even in them there was no dangerous laceration. With a slow dilatation, twenty minutes or more, up to 6 or 7 cm., there was not much more danger of lacerated cervix than in the average labor.

If the cervix was not easily dilated with Bossi's dilator after the bougies had been in place twenty-four hours, a slow dilatation with bags, or a rapid delivery by hysterectomy was available. He thought that Dr. Richard C. Norris's proposition deserved careful attention. It was to dilate the cervix up to 7 cm. with an improved and modified Gau's dilator, then to insert bougies and the largest sized Voorhees bag, partially filled with water. But even with this combination of all the plans of inducing labor, an apathetic uterus demanded operative delivery in addition, just as it did with bougies alone, bags alone, or both together, and in four fifths of the cases bougies alone would be enough without the extra trouble and discomfort entailed by the other methods. Nevertheless, Norris's technique was an excellent one, and would often be useful, especially in cases at a distance, where the consultant would be detained until the labor was over.

Dr. W. REYNOLDS WILSON's experience in the induction of labor had been mostly confined to cases of threatened eclampsia and placenta prævia. He had had more or less experience with induction of labor for contracted pelvis. In his opinion, there were two classes of cases to be considered in the induction of labor. One was that which yielded readily, not only to the bougie, but to careful packing of the cervical canal and vagina,

which he considered a very important adjunct to the use of the bougie. In another class of cases the introduction of the bougie would not cause softening of the cervix or promote uterine contraction, and Dr. Norris's remark in reference to the mechanism of contraction suggested the possibility of the condition being one of reflex action. He stated that there was never any dilatation of the cervix without a corresponding degree of contraction in which the whole uterine organ took part; and if this was borne in mind, it would reveal how absolutely unnatural mechanical dilatation was in most cases. There was a set of cases in which the cervix was elongated and the reflexes were absent, where the bougie was absolutely ineffective and the bag also very probably would be ineffective. He thought the only possible way to induce dilatation in these cases was to attempt to soften the cervix by careful packing, then by manual dilatation afterward, making allowance for the fact that time was the most essential element in the procedure. These undilated cases would always remain difficult cases, and it was a mistake to believe that they must be treated by methods of successive mechanical dilatation, because the prolonged treatment and the want of observance of the proper precautions against infection would probably all be against the interest of the patient.

Dr. Wilson had noticed in certain cases where it had been necessary to induce labor that the unyielding quality of the cervix was accompanied with a condition of cervical gonorrhœa. These cases were apt to be followed by symptoms of local infection and by chronic subinvolution. He believes also that it would be well to call attention to the shock which accompanied accouchement forcé in these cases. The eclamptic cases were those which yielded most quickly to dilatation. They were not the cases in which to perform accouchement forcé. When rapid dilatation was spoken of, it might be that that procedure was meant, but where the eclamptic attack had really come on, the chances were that the labor could be carried on rather promptly. He considered the rapid termination of labor in eclampsia conservative treatment. In order to cure an eclamptic patient, she must first be relieved of her pregnancy. He thought the most modern theory of eclampsia rather explained that; the syncytial tissue found its way into the maternal circulation, causing to be created in the serum a corresponding and compensating antidote to the poison which had been described by the Germans as syncytiolysin. If this compensatory or over-coming serum was not sufficiently produced, then the poison was not counteracted. On the other hand, if the antidote was produced in too great an amount to be neutralized, it in turn acted as an irritating toxine. This he regarded as a very ingenious and very interesting theory of the production of eclampsia. He thought that, if it was a sound theory, as soon as the syncytial tissue ceased its activity the patient should be relieved of the poison; and therefore emptying of the uterus rather favored, not the elimination of the poison, but the cessation of its production.

(To be concluded.)

Book Notices.

A Textbook of Pathology. By JOSEPH MCFARLAND, M. D., Professor of Pathology and Bacteriology in the Medicochirurgical College of Philadelphia, etc., With 350 Illustrations, a Number in Colors. Philadelphia: W. B. Saunders & Co., 1904. Pp. 818. (Cloth, \$5.00; sheep or half morocco, \$6.00.)

Textbooks on pathology may in general be classified into two main groups, one group including such complete monographs on the subject as may be best exemplified by that of Ziegler, the second group including such smaller textbooks as are suitable for the student and practitioner, such for example, as the well-known text of Delafield and Prudden. No one has as yet attempted to produce in English a book which can replace Ziegler in its encyclopædic scope and bibliographical completeness. The writer of the volume before us has attempted to follow a middle path, the difficulties of which he acknowledges in his preface. A great deal of matter has been introduced into the text which is not commonly found in works confined strictly to gross and microscopical pathology. Discussions of the clinical phases of disease are not infrequent. Under the pathology of nutrition we find, for example, a discourse on the causes of uræmia and the dietary errors which underlie gout, a paragraph on phosphaturia and oxaluria, a discussion on the composition of the fæces, a classification of diarrhœas, and, finally, some remarks on the fate of the final products of the constituents of the food. It can easily be seen that if the author treats the subject of pathology with any fullness and also includes the clinical symptoms and physiological chemistry of the disease, the extent of the text must be very great. This question of bulk has been met by the use of two sizes of type, of which even the larger is somewhat too small for easy reading.

A thorough review of the subject matter of the volume is impossible in the short space at our disposal, but the volume impresses the reviewer as on the whole clear and full. A few of the discussions, however, are not fully up to date, as an example of which we may take the chapter on the blood. On the first page, the formula for sodium carbonate is incorrectly given. The basophile cell has long been recognized as constantly present in small numbers in the blood of adults, and though Cabot is quoted as saying that it does not occur in normal blood, that author has changed his opinion. Cabot is again misquoted as saying that a myelocyte has a diameter of fifty micra. Such myelocytes, if they existed, would find it difficult to pass through the peripheral capillaries. It is hardly true either that eosinophilia is always present in gout, uræmia, oxaluria, and epilepsy, and that in malignant disease the number of eosinophiles is reduced. Such errors mar an otherwise excellent book, and the author should have taken care to have some specialist in the subject of blood diseases criticise his text for him, for no one person can cover the entire subject of pathology at the present time.

The chapter on the disease of the female genital organs is full and very well illustrated. That on the diseases of the brain and spinal cord is perhaps

the least satisfactory in the volume. The bacterial side of pathological anatomy is excellently presented and very fully given. The illustrations are in general exceedingly good. Some of them are taken from older textbooks, but many have been freshly drawn or are from photographs of cases seen by the writer. All of those which bear the signature of J. D. Z. Chase show the hand of the experienced artist and illustrator.

Though it is to be regretted that all bibliographical references have been omitted, the author of the text may certainly be congratulated on the results of his first edition. In the second we may expect to find the subject matter brought fully up to date.

Diet in Health and Disease. By JULIUS FRIEDENWALD, M. D., Clinical Professor of Diseases of the Stomach in the College of Physicians and Surgeons, Baltimore, and JOHN RUHRÄH, M. D., Clinical Professor of Diseases of Children in the College of Physicians and Surgeons, Baltimore. Philadelphia: W. B. Saunders & Co., 1905. Pp. 689. (Cloth, \$4.00.)

The authors state that it has been their aim to prepare a practical work that would give a fairly concise account of the different kinds of foods, their compositions and uses, and of the principles of diet, both in health and in disease. There is a brief account of the chemistry and physiology of digestion, and there is a more lengthy description of the classes of food and their uses. Diet for infants and for children, for the aged, for pregnancy, and for various infectious and organic disease are described in detail. To complete the work the army and navy rations and the dietaries of public institutions are given. It is not too much to say that this is a most satisfactory work of its class.

An Elementary Treatise on the Light Treatment for Nurses. By JAMES H. SEQUEIRA, M. D., Lond., M. R. C. P. Lond., F. R. C. S. Eng., Physician in Charge of the Skin Department and Lecturer on Dermatology at the London Hospital. London: The Scientific Press, 1905. Pp. 83. (Price, 2s. 6d.)

The author has found in his experience at the London Hospital that care in the details is essential to success with the light treatment, so he has prepared this little monograph with particular attention to that elementary consideration of details that will make the method intelligible to the nurse. In the main he has followed the methods of Finsen's Light Institute in Copenhagen, with such modifications as his experience has indicated.

Miscellany.

A Simple Method of Generating Formaldehyde Gas.—Henry V. Walker, of the Brooklyn Department of Health, says in an article on this subject in the *Journal of the American Chemical Society*, for March, 1905: The method of generating formaldehyde gas for fumigating purposes, which I shall describe, has been devised with the object of overcoming certain difficulties which attach to the methods generally in use, and which have prevented the adoption of formaldehyde as a fumigating agent

in municipal work. Formaldehyde generators are complicated and rather expensive machines, very liable to get out of order, and requiring frequent repairs and replacement. The time required to generate sufficient gas by means of these machines to fumigate an apartment, is a further objection. The use of solid polymerized formaldehyde (paraform), which is vaporized by means of a burning charcoal cone, obviates some of the difficulties which are encountered with the machines. Unfortunately, paraform as a fumigating agent leaves much to be desired as to efficiency. This is due to several causes, chief of which are the absence of moisture, the complete combustion of a large part of the paraform, and the volatilization of the paraform as such, instead of its decomposition into simple (gaseous) formaldehyde. The use of burning fuel in a sealed apartment also presents a constant source of danger and frequently causes damage to carpets and furniture.

The method of generating formaldehyde gas from its aqueous solution, which is the subject of this paper, consists in utilizing the property of lime of combining with water, and thus to remove the solvent and liberate the gas. The addition of lime to aqueous formaldehyde, however, is not an efficient means of generating formaldehyde gas for two reasons:

(1) The mere ebullition of such a solution does not suffice to expel the gas.

(2) Calcium hydroxide reacts with aqueous formaldehyde, forming carbonhydrates as acrose, formose, and their decomposition product, methylenetan.

The first of these difficulties is avoided in the process about to be described by using a sufficient quantity of lime to combine with all the water contained in the formaldehyde solution. The lime is used, not as a calorific body but as a dehydrating agent. The second difficulty mentioned is overcome by the addition of a substance such as sulphuric acid or aluminum sulphate, which reacts with lime to form an insoluble compound. It has been found, as was to be anticipated, that the reaction between calcium hydroxide and formaldehyde is dependent upon the hydroxide being present in solution, thus facilitating molecular contact and chemical reaction. The bodies mentioned (sulphuric acid, sulphate of aluminum, etc.), by keeping the reacting mixture free from calcium hydroxide in solution, prevent condensation of the formaldehyde.

When sulphuric acid is used, the fumigating liquid is made by adding to the commercial 40 per cent. formaldehyde solution about one third of its volume of commercial sulphuric acid. Eight fluid ounces of this mixture, with one pound of lime, are required for each one thousand cubic feet of the apartment to be fumigated.

A serious objection to the sulphuric acid mixture is that upon standing the formaldehyde is converted into solid polymerized formaldehyde (paraform), which separates out in the form of a deposit closely adherent to the bottle. The use of this mixture has therefore been abandoned in favor of a mixture containing aluminum sulphate instead of sulphuric acid, as this mixture does not deposit paraform.

The mixture is made by dissolving twenty to twenty-five pounds of commercial aluminum sulphate in five gallons of hot water, and mixing this

solution with fifteen gallons of 40 per cent. formaldehyde solution. Eight fluid ounces of this mixture and one pound of lime are used for one thousand cubic feet. It is necessary to use a lime which slacks rapidly with cold water, as this mixture is not so vigorous in action as the sulphuric acid mixture. The lime should be used in the form of coarse powder or small lumps.

The method has the advantages of not requiring any special form of apparatus, of cheapness, and freedom from danger of fire. In municipal practice it has given most excellent results, over 90 per cent. of successful fumigations, tested by *Bacillus pyocyaneus*, being obtained. This high degree of success is doubtless largely due to the great rapidity with which the gas is evolved, a sufficient quantity to fumigate an ordinary apartment being liberated in from five to ten minutes.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending May 6, 1905:

Smallpox—United States.

Places.	Date.	Cases.	Deaths.
Dist. of Columbia—Washington.	Apr. 22-29.	1
Florida—Jacksonville.	Apr. 22-30.	5
Illinois—Chicago.	Apr. 22-29.	21
Illinois—Danville.	Apr. 22-29.	3
Louisiana—New Orleans.	Apr. 22-29.	16
Five cases imported.			
Missouri—St. Joseph.	Apr. 22-29.	3
Missouri—St. Louis.	Apr. 22-29.	21
Nebraska—South Omaha.	Apr. 22-29.	1
New York—New York.	Apr. 22-29.	1
Ohio—Cincinnati.	Apr. 21-28.	4
Ohio—Toledo.	Apr. 15-22.	1
Pennsylvania—Allentown.	Apr. 22-29.	3
Infection imported.			
Pennsylvania—Lebanon.	Apr. 22-29.	3
Pennsylvania—Steelton.	Apr. 22-29.	1
Pennsylvania—York.	Apr. 22-29.	13
South Carolina—Charleston.	Apr. 22-29.	4
Tennessee—Memphis.	Apr. 22-29.	9
Wisconsin—Lacrosse.	Apr. 15-22.	2
Wisconsin—Milwaukee.	Apr. 15-29.	6

Smallpox—Foreign.

Canada—Hamilton.	Apr. 20-27.	2
Chile—Antofagasta.	Jan. 24-31.	1
France—Marseilles.	Mar. 1-31.	1
France—Paris.	Apr. 4-15.	29

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending May 3, 1905:

- ADAMS, F. B., Acting Assistant Surgeon. Granted leave of absence for ten days from April 29th.
- BURKHALTER, J. T., Assistant Surgeon. Bureau telegram of April 24, 1905, granting Assistant Surgeon Burkhalter leave of absence for three days from April 27, 1905, amended to read two days.
- CARMICHAEL, D. A., Surgeon. Granted leave of absence for fourteen days from May 12th.
- CURRIE, D. H., Passed Assistant Surgeon. To report to Medical Officer in Command, marine hospital, San Francisco, Cal., for temporary duty.
- EAGER, J. M., Assistant Surgeon General. Assigned to duty in charge of the Bureau Division of Sanitary Reports and Statistics.
- GAHN, HENRY, Pharmacist. To proceed to Washington, D. C., for special temporary duty.
- GIBSON, F. L., Pharmacist. Granted leave of absence for twelve days from May 6th.
- ROBINSON, D. E., Passed Assistant Surgeon. Detached from the marine hospital, Port Townsend, Wash., and directed to report to Medical Officer in Command, Port Townsend Quarantine, for temporary duty.
- ROSSELLO, M. M., Acting Assistant Surgeon. Granted leave of absence for twenty-three days from May 15th.
- SAFFORD, M. V., Acting Assistant Surgeon. Granted leave of absence for two days from April 30, 1905, under paragraph 210 of the regulations.
- VAUGHAN, G. T., Assistant Surgeon General. Relieved from duty in charge of the Bureau Division of Sanitary Reports and Statistics, and assigned to duty in charge of the Bureau Division of Marine Hospitals and Relief.
- WOODS, C. H., Pharmacist. Granted leave of absence for thirty days from May 15, 1905.
- WOODWARD, R. M., Surgeon. To proceed to Providence, R. I., for special temporary duty.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending May 6, 1905:

- BORDEN, W. C., Major and Surgeon. Detailed to represent the Medical Department of the United States Army at the meeting of the Interstate National Guard Association, at St. Paul, Minn., June 19, 1905.
- BRUNS, EARL H., First Lieutenant and Assistant Surgeon. Appointed an assistant surgeon, with the rank of first lieutenant, from May 1, 1905.
- DUNCAN, WILLIAM A., First Lieutenant and Assistant Surgeon. Appointed an assistant surgeon, with the rank of first lieutenant, from May 1, 1905.
- EKWURZEL, GEORGE M., First Lieutenant and Assistant Surgeon. Left West Point, N. Y., with the cadets, en route to Gettysburg, Pa., for field exercise.
- GIBNER, HERBERT C., First Lieutenant and Assistant Surgeon. Appointed an assistant surgeon, with the rank of first lieutenant, from May 1, 1905.
- RAYMOND, H. I., Major and Surgeon. Leave of absence extended two months.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 6, 1905:

- ANGENY, G. L., Passed Assistant Surgeon. Detached from the Naval Station, Culebra, W. I., and ordered home to await orders.
- BRISTER, J. M., Passed Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, Pa., and ordered to the *Atlanta*.
- DUNN, H. A., Assistant Surgeon. Ordered to the *Terror*.
- HAMMER, A., Pharmacist. Detached from the Navy Yard, New York, N. Y., and ordered to the Army General Hospital, Fort Bayard, N. M., for treatment.

HOLCOMB, R. C., Passed Assistant Surgeon. Detached from the *Cleveland* and ordered to the Naval Station, Culebra, W. I.

HUNTINGTON, E. O., Surgeon. Detached from the Naval and Marine Recruiting Stations, Chicago, Ill., and ordered to the *Albatross*.

MOORE, J. M., Passed Assistant Surgeon. Ordered to duty at the Naval and Marine Recruiting Stations, Chicago, Ill.

THOMPSON, J. C., Passed Assistant Surgeon. Detached from the *Albatross* and ordered home to await orders.

WHEELER, W. M., Surgeon. Ordered to the *Cleveland*, sailing from New York about May 10th.

Births, Marriages, and Deaths.*Born.*

SALMON.—In Brooklyn, N. Y., on Thursday, April 27th, to Dr. Thomas W. Salmon, United States Marine Hospital Service, and Mrs. Salmon, a son.

Married.

ALLEN—BROWNING.—In Columbus, Ohio, on Tuesday, April 25th, Dr. Albert Edward Allen and Miss Dora Enola Browning.

COCA—CLEWS.—In Wayne, Pennsylvania, on Thursday, April 27th, Dr. Arthur Fernandez Coca and Miss M. A. Clews.

DRAPER—FORD.—In St. Louis, Missouri, on Wednesday, April 26th, Dr. James Avery Draper, Jr., and Miss Elsie Ford.

HENNING—MEAGHER.—In St. Paul, Minnesota, on Wednesday, April 26th, Dr. A. F. Henning and Miss Mary B. Meagher.

PAYNE—STADIGER.—In Philadelphia, on Saturday, April 29th, Dr. Norman W. Payne and Miss Margery Stadiger.

PILCHER—FINLAY.—In Montclair, New Jersey, on Wednesday, April 26th, Dr. Paul Monroe Pilcher and Miss Mary Finlay.

PRIME—HENDRICKS.—In San Francisco, California, on Wednesday, April 26th, Dr. Thomas Prime and Mrs. Mary D. Hendricks.

ROSS—HINCKLEY.—In Brooklyn, N. Y., on Wednesday, May 3rd, Dr. William Holmes Ross and Miss Grace L. Hinckley.

SANDS—MILLSPAUGH.—In Evanston, Illinois, Dr. Theodore Sands and Miss Elizabeth Millspaugh.

SWANN—JOHNSTON.—In Kansas City, Missouri, on Wednesday, April 26th, Dr. A. T. Swann and Miss Louise C. Johnston.

Died.

HAMMOND.—In San Francisco, California, on Thursday, May 4th, Dr. William Hammond, in the eighty-eighth year of his age.

HILLER.—In San Francisco, California, on Tuesday, April 25th, Dr. D. Albert Hiller, in the sixty-sixth year of his age.

MUCKLE.—In Philadelphia, on Saturday, April 18th, Dr. Alexander Muckle, in the seventy-sixth year of his age.

NEWMAN.—In Lawrence, Kansas, on Saturday, April 29th, Dr. Albert Newman, in the eighty-second year of his age.

PARKER.—In New Orleans, Louisiana, on Thursday, April 27th, Dr. James Porter Parker, in the twenty-ninth year of his age.

POTTER.—In Brighton, Maine, on Tuesday, April 18th, Dr. N. P. Potter, in the sixtieth year of his age.

PUGH.—In Burlington, New Jersey, on Sunday, April 30th, Dr. J. Howard Pugh, in the seventy-ninth year of his age.

SCUDDER.—In Redlands, California, on Wednesday, April 19th, Dr. William Byrd Scudder.

METACARPAL FISSURE, A FRACTURE TYPE NOT HERETOFORE DE- SCRIBED, AND SOME POINTS REGARDING TREATMENT OF METACARPAL FRACTURE.

By CARL BECK, M. D.,

NEW YORK,

PROFESSOR OF SURGERY IN THE POSTGRADUATE MEDICAL SCHOOL
AND HOSPITAL, VISITING SURGEON TO THE ST. MARK'S
HOSPITAL AND THE GERMAN POLIKLINIK.

Text-books written before the Röntgen era treat fractures of the metacarpal bones as a *quantité négligeable*, but skiagraphy has now established the undeniable fact that a large number of alleged dislocations and contusions of the metacarpal region are in reality fractures. Moreover, it has not only given us the most reliable means for differentiation, but has also increased our knowledge in regard to the details of metacarpal injuries.

It is, for instance, due to the Röntgen method that I had the privilege to correct the erroneous old dictum that the displacement following fracture of the metacarpal bone is either dorsal or palmar. My Röntgen observations prove that

in the majority of cases the displacement is decidedly lateral, or both lateral and dorsal (see this *Journal*, August 4, 1900).

Fig. 1 illustrates the dorsal type of displacement. It shows union of the fragments in the displaced position, no effort at reduction apparently having been made. When seeing the patient, four weeks after the injury, I made a forcible effort at reduction, but in vain. The deformity being considerable now, reduction after separation with the chisel was suggested.

It is noteworthy that Fig. 1, taken in the lateral position, shows the character of the displacement distinctly, while Fig. 2, taken at the same time in the dorsopalmar position, gives the erroneous impression that the fragments were in proper apposition. Still, for the experienced eye the large amount of callus around the fractured area would cause suspicion. However, it is a further proof of the necessity of always taking

FIG. 1.—Upward displacement in fracture of the metacarpus indicates.

FIG. 2.—Dorsopalmar view of same case, not showing displacement.

two skiagraphs in different positions in order to obtain a correct appreciation of the situation.

After reposition of dorsal or palmar displacement is complete by downward or upward pressure, immobilization by a plaster of Paris dressing or by coaptation splints keeps the fragments in situ. But it is evident that if there is lateral displacement the same method of reduction and immobilization will not influence the fragment. Lateral displacement requires lateral influence. This can be exerted very simply by lightly pressing rubber drainage tubes between the adjoining interosseous spaces, where they are kept in situ by adhesive plaster strips. Thus recurrence of the displacement is absolutely prevented. The hand may then be surrounded by a plaster of Paris dressing or preferably by a moss splint, which, after being dipped in cold water, well adapts itself to the contours of the body.

I had during the period of six years following that observation had frequent opportunities to study cases of metacarpal fractures and have seen neither deformities nor disabilities follow that course of treatment. Since the Röntgen technique has become so greatly improved by the use of the diaphragm, my attention was called to a fracture type not heretofore described, viz., the fissure above the metacarpal epiphysis.

In the majority of cases the line of metacarpal fracture is found in the middle of the bone, where it is thinnest. The direction is generally transverse, but the oblique type is sometimes found. When there is dorsal or palmar displacement the fracture signs are well marked, local pain and tenderness, deformity, abnormal mobility, disturbance of function, and sometimes crepitus being distinctly noticeable. There is often local ecchymosis. Should there be any yielding to the finger as it is thrust against the corresponding metacarpal epiphysis the diagnosis of fracture is established. If so, the pain following the manipulation is considerable. As a rule, therefore, these procedures should not be resorted to for diagnostic purposes, because skiagraphy is much safer and entirely painless.

Skiagraphy is so much the more advisable since it has frequently been proved that when all the signs mentioned, with the exception of swelling and pain, were absent, there still was a fracture, the presence of which was revealed only by the Röntgen method. It should furthermore be considered that not infrequently it happened that during the first few hours after the injury, when there was little effusion in the surrounding tissues, the fracture signs were marked, while a few hours later, when the effusion became

considerable, no more abnormal mobility or deformity could be detected, the latter being masked by the greatly swollen tissues. Finally it should not be lost sight of that in view of the presence of a large amount of tumefaction metacarpal fracture may be feared, while the Röntgen method proves that the bones are intact, an extensive contusion only being present. Now, while such cases are best treated by massage, fractures with no displacement demand immobilization; such as show displacements demand reposition before immobilization. If there is a non-displaced fracture or fissure it is manifestly inappropriate to use massage or similar procedures. Thus it becomes evident that proper therapeutical steps can be taken only on the basis of a correct diagnosis.

As mentioned before, the fracture line is usually found in the middle of the bone, where it is thin-

FIG. 3.—Ligaments of the right third finger from the radial side.

nest. Sometimes there is epiphyseal separation, as first recognized by Malgaigne. Cases of oblique and transverse fracture above the epiphysis have been illustrated by me in previous publications (see text-books on fractures and Röntgen diagnosis and therapy). In all these cases there was more or less lateral displacement. The symptoms of this type resemble those of dislocation and were almost always mistaken for such in former years.

Now, at the early era of the Röntgen rays I repeatedly had a chance to see cases which in view of the presence of local pain and swelling made me suspect a fracture. Still skiagraphy showed no evidence of it. I am certain, however, that at times I noticed a thin fracture line above the epiphyseal end, but not distinct enough to impress me. But as I have observed the same lines in cases of alleged contusions from time to time, and especially as I recognized an additional longitudinal fissure line so distinctly that it could be demonstrated without the aid of the diaphragm (Fig. 4), I feel justified in calling the attention of my colleagues to this new observation.

As to the ætiology of the injury, I may say that the nature of the ligamentous arrangement, as is evident from studying Fig. 3 (after Fick), suggests that whenever the middle of the diaphysis is not as thin as usual a fracture will occur above the attachment of the ligaments, that is, in a slightly oblique, if not semilunar, direction (see illustrations). Especially is this so as the result of a moderate degree of indirect violence (a blow of the fist or a fall on the knuckles), when the middle of the diaphysis is as strong as illustrated in Fig. 4. Here the fracture line extends a little further in a more or less longitudinal direction.

It scarcely need be mentioned that the treatment of this injury requires nothing but immobilization. Rough manipulations, made for diagnostic purposes, are apt to increase the extent of the injury and may even produce a displacement, which Nature herself prevented by the coherent periosteum.

In the face of the skiagraphic proof of this injury it appears natural that massage, so commendable in contusions, would be injurious here. All the patient needs is proper protection of the hand for two or three weeks, which may consist in a small plaster of Paris dressing or in a moss board dressing, as already described. A deformity in this region may mean nothing to a bricklayer, but a talented young violinist may by this injury lose his chance of becoming a second Paganini.

Fig. 4 illustrates the oblique and longitudinal

FIG. 4.—Fissure at lower end of fifth metacarpal bone.

fissure above the lower epiphysis of the fifth metacarpus in a man of twenty-five years of age, who struck the face of an assailant with his fist. This was followed by intense pain at the fifth metacarpophalangeal joint. When I saw the patient, on the following day, there was great local pain and tenderness, as it is usually found in fractures. Ecchymosis was absent. Fluoroscopic examination revealed no bone injury, but skiagraphy showed the fissure line distinctly. The hand was surrounded with a bracelet of moss board, extending from the wrist to the second joint of the middle finger. This enabled the patient to do light work with his hand, ultimate recovery being perfect two weeks after the injury.

The Mississippi Medical and Surgical Association, composed of colored graduates in medicine, elected the following officers at their recent meeting at Jackson: President, Dr. J. M. May, of Westside; first vice-president, Dr. C. W. Raines, of Clarksdale; second vice-president, Dr. J. E. Shanks, of Natchez; treasurer, Dr. L. T. Miller, of Yazoo City; secretary, Dr. B. E. Conner, of Brookhaven; delegate to the American Medical Association, Dr. C. W. Raines.

A SUCCESSFUL METHOD OF TREATING FRACTURE OF THE FEMUR IN INFANCY.

By WALTER G. STERN, M. D.,

CLEVELAND,

ORTHOPEDIC SURGEON TO MOUNT SINAI HOSPITAL AND TO THE CHILDREN'S FRESH AIR CAMP.

The majority of fractures of the femur observed in children under the age of 12 months are caused by the various efforts at traction during labor. The usual methods of treating such fractures fail when dealing with so small a subject whose needs and wants are so different from those of the adult; and union with marked deformity, necessitating a painful and tedious correction in the third or fourth year, and considerable shortening with subsequent limp or even inability to walk in due time, have not been infrequent results. Again, the pain from a badly held fracture may cause constant fretting and crying with inability to nurse, worry to the mother and consequent deterioration of the milk, starvation of the child, and the usual train of gastroenteric symptoms.

I shall describe a method of treatment which has proved uniformly successful in my hands in a small number of cases. It is, however, the only completely successful way of treating the newly born and the very best for all children up to the age of two years. The necessary requirements for successful treatment of fractures of the femur in sucklings are:

- 1st. Ability to nurse properly at breast.
- 2nd. Cleanliness.
- 3rd. Ability to hold fragments in apposition without subsequent deformity.
- 4th. Freedom from pain on moving child for necessary changes of clothing, etc.
- 5th. Ability to prevent shortening.

Of the methods in common use, lateral or anterior splints, plaster or glass casts and braces meet only the first requirement, inasmuch as the mother can suckle the child by placing it at the breast in the usual fashion; but they are far from cleanly, the bandages are soon covered with urine and feces, they do not hold the ends of the fracture on account of the smallness of the parts and lack of proper leverage, and permit of deformity and shortening. In my opinion a child is almost as well off untreated. Posterior splints are entirely out of the question. Horizontal extension meets all requirements, except that it is very uncleanly, and all efforts of the child in crying and struggling counteract the extension.

Vertical extension in the manner to be described meets all the requirements in an ideal way. It enables the mother to nurse the child with very little effort and enables the nurse to keep the child scrupulously clean, as it is impossible for it to soil the dressings, and the diaper can be changed without difficulty or without causing pain. It holds the fragments together, allows only a minimum of shortening, and is easily applied.

Before the third day it is wise to refrain from extension, for the safety of the mother demands that she shall lie quietly at rest and nurse the child after the usual fashion. I have been able to secure enough fixation to keep the child quiet by bundling it in a feather pillow (Fig. 1), just as it is prac-

FIG. 1.—Child with fracture quieted by immobilization in a feather pillow.

tised by the peasantry of Continental Europe. After the third day the limb is placed in vertical extension and kept there for at least three weeks. The child rests on a pillow placed on a low stand next to the bed and should not be above the level of the mattress. Its body is parallel to the length of the bed and its head at about the position of the mother's breast. This enables her to nurse it by merely rolling over on her side and placing either nipple in its mouth; a pillow behind her back enables her to suckle the child for the customary fifteen or twenty minutes with perfect comfort. If on the third day the mother has fever, or is otherwise incapacitated from nursing the child, it is not placed beside the bed, but in any desired location, and is nursed from the bottle or by a wetnurse. The adhesive straps for the extension are put on in the usual fashion, after the skin has been thoroughly cleansed with alcohol and ether, and should reach

well up over the trochanter. Zinc oxide plaster should always be used, as it is far less irritating to the delicate skin; I have found that by using sterilized zinc oxide adhesive plaster the extension can be left unchanged for the entire three weeks; an adhesive plaster which lacks at all in "stickiness" and is liable to slip, cannot be used. It is impossible in these small limbs to get the extension straps to stay unless they are bound down by circular turns around the malleolus, the top of the tibia, the condyles of the femur and the groin; care should be exercised not to get the circular turns too tight, as that might lead to venous stasis. The groin and buttocks are next carefully bandaged with a two inch bandage of oiled silk, held in place by adhesive strips; next a flannel bandage is carefully applied from the toes to the groin to keep the leg warm, and this again is protected by an oiled silk bandage reaching from the knee to the groin (Fig. 2). No

can be changed at will by adding or taking out salt. In all cases the weight should be just enough to lift the buttock off the pillow. To change the diapers, the child is taken by both feet and lifted up a little,

FIG. 2.—Dr. Stern's method of securing extension of a fractured femur in a child.

spica turns about the pelvis are to be used. In none of my cases were these bandages soiled either by urine or faeces, except in one case where a boy had an unpleasant habit of urinating in the nurse's face when the diaper was taken off, but here the external bandage of oiled silk saved the dressings. The extension is carried upwards with wire to a hook firmly fastened into the ceiling, then over for three or four feet, so as to get the weight away from the baby, and then down over another hook for a foot or two, where the weight is placed out of reach of either head or hands (Fig. 3). I have found half of a five pound bag of salt the best form of weight; it is cheap, can be easily fastened, and the weight

FIG. 3.—Weight, arranged out of reach, to raise buttock from pillow.

and after cleansing and dressing, the legs are let go and a slight pull is given to slack up the extension. With the leg balanced by proper extension, the child may squirm, kick, cry, throw itself about or even, if old enough, try to suck its toes, but it cannot get away from, or neutralize the vertical pull as it could a horizontal one. The relief from pain is almost immediate, the children stop fretting and crying at once, begin to nurse properly, thrive and gain in weight. No pain ought to be caused in washing or clothing them, and with care the sheets and pillows may be changed daily, or a new table or stool substituted for the old one. The only precautions necessary are to have the hooks well fastened into ceiling and to secure the stool or table to the floor, so that no awkward father or inquisitive child shall be able to knock it over. It is impracticable to allow the child to lie in the same bed with the mother.

In most of my cases one or even two weeks had elapsed and one or more of the various fixation methods had already been tried; there was generally a very large callus, the femur bowed into an

anteroposterior arc of about 45°, and marked shortening. It was first necessary to freely break up the callus and apply a rather heavy extension (3½ to 4 pounds). No anæsthetic was given. In all cases the final shortening was so slight as to be negligible, there remained no angular deformity, and good union and a normal callus resulted.

CASE I.—Miriam S., aged 14 days. Referred by Dr. S. Cross presentation, version, extraction, fracture of left femur. Dr. S. immediately applied lateral splints, which soon had to be removed because soiled, a glass cast was next applied, but became soiled, the child cried incessantly and had lost markedly in weight; did not nurse much. Status, January, 1901: Fracture of left femur at junction of middle and upper third, large callus, angular deformity of about 80°, marked shortening, buttocks and groin markedly excoriated and irritated. I broke up the callus, applied vertical extension, and the crying ceased at once, and within three days the child was nursing regularly, and in a week a gain could easily be noticed. The plasters were changed frequently on account of former excoriation of the skin. Child no longer soiled dressings and was discharged cured in February, 1901; no deformity; slight shortening.

CASE II.—William R., aged 1 day, referred by Dr. F. Breech presentation and accoucheur had to pull on legs to get them out. Fracture of left femur. Status, June, 1901: Strong, healthy, crying child, fracture of femur in middle of upper third; no callus; shortening; marked swelling; no suppuration. I bundled the child in a feather pillow for two days so that its mother could nurse it undisturbed. Vertical extension on fourth day; on fifth day adhesive plasters slipped off and weight and limb came down with a thud. I reapplied extension and renewed plasters every seven days; after twenty-five days the child had gained in weight, and did not cry, the fracture had united firmly, with moderate callus, no deformity, no appreciable shortening, no excoriations. Discharged cured.

CASE III.—Eva R., aged 19 days. Delivered by midwife. Had a hard time at breech delivery. Child had cried ever since, and held its leg in a peculiar position so that parents feared dislocation of hip. Status June, 1902: Emaciated, crying child, fracture of left femur, angular deformity of 50°, marked shortening, large amount of callus. I broke up callus without an anæsthetic, and applied vertical extension for four weeks; child ceased to cry almost immediately, gained in weight, was kept remarkably clean (considering parents!), had no deformity, but slight shortening, no pressure sores, and no excoriations. Discharged cured.

CASE IV.—Mamie S., aged 13 days, referred by Dr. S. Difficult labor, version, fracture of right leg; splints applied which would not hold. Child cried incessantly and limb was markedly deformed. Status, July, 1904: Crying child, fracture of right leg at middle of upper third, angular deformity of 30°, marked external rotation of leg, large soft callus. I broke up callus and applied vertical extension; child stopped crying within five minutes after extension was applied; left undisturbed for

twenty-four days; at end of this time no shortening, no deformity, good union, no excoriations, no pressure sores. Discharged cured.

CASE V.—Baby N., aged 9 days, referred by Dr. D. Normal presentation, but a hard case to deliver, child cried incessantly. On second day discovered a fracture of left femur, used a sort of Thomas's splint, which gave the child no relief, and did not hold fragments. Status, July, 1904: Crying child, buttocks and privates red and excoriated, excoriations from adhesive plaster used to hold splint, pressure mark from splint; fracture of left femur at junction of middle with upper third, marked deformity, slight callus. Vertical extension, left unchanged for twenty-one days, at end of which time there was good union, no shortening, normal callus.

CASE VI.—Baby F., aged 9 months, fell out of buggy. Status, August 21, 1904: Fracture of left femur in middle third. Vertical extension, which was changed once in three weeks. Child played and was content, tried to get toes of left foot in mouth. Somewhat neglected by hospital attendants and clothes were always soaked with urine, but dressings were always dry. Status, September 8th: Good union, no deformity, good callus, no shortening. Discharged cured.

CASE VII.—Irma N., aged 6 months, had fall at Wade Day Nursery two days before; had cried ever since. Status, August 15, 1904: Fracture in upper third of right femur. Vertical extension left undisturbed for twenty-two days. Discharged cured, no deformity, no shortening.

Licensed to Practise Medicine in Kansas—The following have passed the necessary examination held in Kansas City, Kas., on April 25th and 26th:

E. P. Harrison, A. R. Holmes, L. M. Hinshaw, J. F. Heath, J. F. Hughes, F. E. Harvey, C. H. Helman, W. S. Hadinburg, R. W. Hull, T. R. Heath, D. G. Jones, P. S. Jones, W. W. Johnston, C. F. Kyser, A. Jersey County, Ill., Medical Society.—The forty-ninth annual meeting of the Jersey County Medical Society has elected the following new officers: President, Dr. J. S. Williams; vice-president, Dr. L. T. Waggoner; secretary-treasurer, Dr. A. K. Van Horne. The society is arranging to celebrate its golden anniversary next year.

PUBERTY AND ADOLESCENCE IN THEIR RELATION TO THE ÆTIOLOGY OF EPILEPSY.*

By WILLIAM P. SPRATLING, M. D.,

SONYEA, N. Y.,

MEDICAL SUPERINTENDENT OF THE CRAIG COLONY FOR EPILEPTICS, PRESIDENT OF THE NATIONAL ASSOCIATION FOR THE STUDY OF EPILEPSY, MEMBER OF THE NEW YORK ACADEMY OF MEDICINE, MEMBER OF THE AMERICAN MEDICOPSYCHOLOGICAL ASSOCIATION, ROCHESTER PATHOLOGICAL SOCIETY, ETC.

Puberty is defined as "That period of life at which a person of either sex becomes functionally capable of generation." By the Roman civil law, as well as by the common law, the age of puberty at which capacity to marry was legally presumed to exist, was 14 years in males and 12 in females.

Adolescence is defined as "The process of growing up. The state or period of growth from childhood to manhood, or from puberty to maturity: in law, the period from 14 years in males and 12 in females till 21 years of age." (Wharton in Abbot's *Law Dict.*)

Puberty is more circumscribed in years than adolescence, for while adolescence, which begins at the termination of childhood, includes puberty, it extends several years beyond the period at which puberty is generally held to be over.

While we are most interested just now in the influences that are particularly apt to prevail during the twelfth to the sixteenth year, we may for all practical purposes consider puberty and adolescence as embracing the same period.

Adolescence, in a sense, is a new birth. Important and vital functions never before present arise at that time. The qualities of body, function, and mind that emerge at puberty are new, ill understood, and strange. Development at this time is less steady and more saltatory.

Some individuals linger long in the childish stage and advance late or slowly, while others push on with a sudden outburst of impulsion to early maturity.

The powers of diseases peculiar to childhood abate, and liability to the diseases of maturity begins, so that with the liability to both, it is not strange that the dawn of the ephebic day is marked at the same time by increased morbidity, but by diminished rate of mortality. The entire organism has grown significantly more complex.

The momentum of heredity often seems insufficient to enable the child to achieve this great revolution and come to complete maturity, so that every step of the way to a higher development is

strewn with wreckage of body, mind, and morals. There is not only arrest, but perversion.

One of the gravest dangers is our persistent ignoring of the prime importance of establishing normal periodicity in girls, to the needs of which everything else should for a few years be secondary.

Within the bounds of the epoch of puberty, the functions of every sense undergo reconstruction and their relations to other psychic functions change. New sensations, some of them very intense, arise, and new associations in the sense sphere are formed. Haptic impressions, appetite for food and drink, and smell are most modified. The voice changes, vascular instability, blushing, and flushing are increased. Sex asserts its mastery in field after field, and works its havoc in the form of secret vice, debauch, disease, and enfeebled heredity, and, most deplorable of all, sends many thousand youth a year to quacks, because neither parents, teachers, preachers, nor physicians know how to deal adequately and satisfactorily with its problems.

A youth awakes at puberty to a new world, and standing uneducated, unguided, and untrained, understands neither it nor himself.

Character and personality at this period are rapidly taking form, but everything is plastic. Self feeling and ambition are increased, and every trait and faculty is liable to exaggeration and excess. It is all a marvelous new birth, and those who believe that nothing is so worthy of love, reverence, and service as the body and soul of youth, and who hold that the best test of every human institution is how much it contributes to bring youth to the ever fullest possible development, may well ask how far the educational institutions of to-day are capable of satisfying this supreme test.

The preceding remarks concerning the period of adolescence, the nature and quality in general of the developmental changes that occur at that time to give it especial distinction, and the manifold dangers, including psychic, physical, and moral alike that threaten at its door and during its course, are quoted in part from G. Stanley Hall's most admirable work on *Adolescence and Its Psychology*, etc. From a critical study of Dr. Hall's admirable and exhaustive work, I think it should be read by every person who desires a more intimate familiarity with this important period.

EPILEPSY DURING THE ADOLESCENT PERIOD IN WOMEN.

Before considering the frequency with which epilepsy develops in women at this period, I will briefly review the age at which puberty is ordi-

* Read before the fourth annual meeting of the National Association for the Study of Epilepsy, etc., held in the Medical Library, Boston, November 22, 1904.

narily established, so that we may the better see how closely allied this period is with the increase in epilepsy writers on the subject generally note as occurring at this time, and which some go so far as to characterize as the epileptic age, including males and females in these studies alike.

Most observers give geographical position a conspicuous influence in the establishment of the menstrual flow.

Women who live in warm countries reach the childbearing period earlier than do the women of the North.

Bassell found the average age at first menstruation in 4,815 cases in northern Europe to be sixteen years and four months, while the average age for 1,655 cases in southern and oriental lands was twelve years and one month—a difference of four years due to climatic influences.

Hall presents comprehensive studies to show the comparative periods at which menstruation develops in the well to do classes as compared with the poor, and in city as compared with country girls; and I quote the following from him:

Meyer, Germany. (6,000 Observations.)		Kakuskin, Russia.	
Years.		Years.	
Among the Rich.....	15.51	Among the Rich.....	13.0
Among the Poor.....	16.31	Among the Poor.....	13.0
In the Cities.....	15.98	In the Cities.....	14.9
In the Country.....	14.20	In the Country.....	15.3

Tarnowski gives the average age of 5,000 cases in Russia as 16 years.

At twelve American institutions reporting to the Massachusetts Labor Bureau, and representing 1,290 girls, the average age at menstruation was 13.62. In 6,550 cases studied by Krieger in Berlin, the age was placed at the beginning of the fifteenth year.

Nearly all tables show that large girls menstruate earlier than those of small or average size, and nearly all observers agree that blondes precede brunettes.

One of the most instructive studies of the age of first menstruation is that of Lullies based on 3,000 Prussian girls. Although it shows that more cases occur at fifteen than in any other year, the average age is about sixteen. Lullies differs from most earlier observers in believing that the strong begin this function later than the weak. First of all, come large weak blondes, and last come the middle or small sized brunettes. Lullies thinks country girls are at least six months later than city girls. In eighty-three per cent. of all the cases, the periods were regularly established at once, and in seventeen per cent. they were irregular for a time. The average duration of the flow of those in whom it occurred regularly was 4.79

days. Seven and especially eight days are unusually frequent.

In public institutions, like the Craig Colony for Epileptics, where few patients are received before their disease is chronic, and where the intelligence of many is far too inferior to make their statements acceptable at face value, it is difficult to obtain extended and accurate data on the age at which menstruation first appeared.

But in a careful study of 325 women, 126 were found in whom the age at the onset of this function could be established to the month, these ages being, in round numbers, as follows:

During the 10th year.....	2
During the 11th year.....	4
During the 12th year.....	17
During the 13th year.....	29
During the 14th year.....	39
During the 15th year.....	20
During the 16th year.....	8
During the 17th year.....	2
During the 18th year.....	1
During the 19th year.....	1
During the 20th year.....	1

The average age at which menstruation first appeared in the 126 epileptic women cited above was 13.4 years. It would not appear from this that the function of menstruation is changed in any way, either hastened or retarded in its first appearance, by the presence of epilepsy.

It has been quite conclusively shown that epilepsy is most apt to arise at certain epochs or periods, and it is interesting to refer just here to Table A, which shows the age at onset in 1,215 cases, the first eight years, being omitted, the table beginning with the ninth, and being produced purposely to show the very sharp and decided increase in the number of cases when puberty is reached. It is significant that the increase during the twelfth year was mostly among girls, the increase during the fourteenth year being mostly among boys. As a matter of fact we might, in a sense, call the age period from the twelfth to the sixteenth years inclusive the age of essential idiopathic epilepsy. Epilepsy that commences under ten years is apt to be highly tinged with the elements of bad heredity, or to follow a cerebral palsy, or come as a sequela of one of the infectious fevers. The epilepsies of this period are most apt to be followed by pronounced mental impairment. After passing the tenth year or so, the causes of the disease, and its results in a measure, change. Cures are oftenest obtained in cases that originate between ten and twenty years, though they are by no means confined to this period.

We may next note the influence of the menstrual flow in inciting attacks in cases of pre-

existing epilepsy. A table previously made up and published by me¹ shows this quite clearly:

FIG. 1.—Chart showing influence of puberty on epilepsy.

This chart shows how epilepsy increases with the establishment of puberty, the influence of which seems to be most marked in girls during the twelfth year, and in boys during the fourteenth year. After the fourteenth year, a progressive decline sets in that extends to the twentieth year, and the cases of genuine epilepsy that arise after the twentieth year are quite rare. In the diagram the years prior to the ninth are omitted, the sole purpose of the chart being to show the great increase in the number of cases at puberty.

TABLE SHOWING THE INFLUENCE OF THE MENSTRUAL FLOW IN INCREASING THE FREQUENCY OF EPILEPTIC ATTACKS IN PREEXISTING CASES OF THE DISEASE.

- Attacks weekly or oftener in 775 cases.
- Attacks every two weeks in 175 cases.
- Attacks every three weeks in 61 cases.
- Attacks every four weeks in 244 cases.
- Attacks every eight weeks in 42 cases.
- Attacks every twelve weeks in 49 cases.
- Attacks every eight months or over in 30 cases.

The very distinctive rise at the four weeks' period as shown in this table is directly chargeable to the mild excitation caused by the various slightly abnormal influences due to the menstrual flow. No one who has had opportunity for carefully identifying the seemingly trivial causes, as they often appear to be, that are capable of inciting epileptic paroxysms in some individuals, will for a moment doubt the power of the menstrual wave in this respect, especially in neurotic individuals and when the flow is marked by any considerable degree of abnormality and irregularity.

¹ *Epilepsy and Its Treatment*. By W. P. Spratling, M. D., 1904, p. 194.

To further illustrate the possible influence of the menstrual epochs in directly inciting epileptic convulsions in some cases, I reproduce below Engelmann's menstrual curve which shows the rise and fall of the pulse, temperature, blood pressure, muscle force, pulmonary capacity, morbid nervous symptoms, and other abnormal phenomena incident to the menstrual flow.

This curve does not represent the amount or degree, only the time of these undulation; the numbers representing the days from the first to the twenty-eighth; the shaded days, those on which the menstrual flow is in progress, and while every recurrent menstrual period has a close relationship with epileptic convulsions in some—I may even say in many—cases, we will not stop to study this part of the subject now, but pass on to those cases in which the epilepsy seemed originally to appear as a direct and specific result of the establishment of this function.

FIG. 2.—Engelmann's menstrual curve.

CASES THAT ILLUSTRATE THE INFLUENCE OF THE MENSTRUAL EPOCH IN THE AETIOLOGY OF EPILEPSY.

CASE I.—M. D. R., age when admitted to the Craig Colony, 18 years; epileptic three years; family history good, except that mother had chorea when she was 6 years old, the ascribed cause being "fright." Patient had no convulsions in infancy and none during the second dentition. She had the usual childhood diseases, recovering from them without bad after-effects of any kinds.

"On the very day on which menstruation first appeared she was attacked with epileptic convulsions. She was 15 years old at the time. The attacks have continued ever since." (This note is from her history given me by the family physician at the time of the patient's admission.) Her attacks at first were mostly petit mal; later changing to grand mal of great severity, and occurring three to six times in twenty-four hours. Her mental impairment three years after the origin of her epilepsy was pronounced.

The aetiological influence of the establishment of the menstrual flow in the immediate excitation of epileptic convulsions in this case cannot be questioned. The patient came under my care

three years after the onset of her epilepsy, which had become firmly established by that time. Had adequate treatment been instituted *promptly* after the disease arose, there is little doubt that she could have been cured. But the long delay was disastrous, just as long delays are destructive of ultimate cure in cases in which epilepsy follows cranial trauma. The time to operate in such cases is at once. The time to have applied relief measures in the case in question was within two or three months at most after the convulsions first appeared. Three years later they had become fixed beyond the possibility of removal. This would not be true in all cases, but it was true in this. Many public hospitals throughout the country are to-day filled with lost opportunities like this. The motto in such cases should be *treat promptly; treat at once*.

CASE II.—C. F. B., age on admission to the colony, 27 years; epileptic since the 13th year. Family history: Grandfather died of apoplexy; mother died of "internal" cancer; "several cousins insane."

Patient a full term child; no convulsions in infancy or childhood, though she was always "very nervous." First epileptic convulsions occurred when she was 13 years old, and it came *coincidentally with the onset of the first menstrual flow*. The attacks from the first were grand and petit mal, remaining so until after she passed her 30th year. After the 27th year, they began to appear independent of the menstrual period, but they were invariably worse during such periods. Up to the 27th year the attacks came along with the menstrual periods.

For nearly fifteen years after the onset of the epilepsy, the attacks remained such a type as to make but little permanent impression on her mental condition. After that she suffered the characteristic effects of the disease, impaired memory, unreasonable irritability, and fits of marked depression. As soon as these effects began to be apparent to her friends, they permitted a double ovariectomy to be performed; but it was without beneficial result. The operation had been put off too long.

Were it essential, I could cite many cases identical with the two reported. It cannot be questioned that the general disturbance in the mental and physical balance of some young women caused by the establishment of the function of menstruation, is a positive factor in the causation of epilepsy. I believe that in all such cases some predisposition must be present before epilepsy can arise, for the establishment of the menstrual flow should be a purely physiological process incapable of inducing deep seated and lasting pathological changes and conditions.

Women who acquire epilepsy of a certain form as a result of an imperforate uterus (such cases

are occasionally encountered) are not included in this study, even though their epilepsy may appear for the first time in close conjunction with what should constitute the first menstruation, and continue to repeat themselves at such periods in the future.

EPILEPSY DURING THE ADOLESCENT PERIOD IN MALES.

When we come to study puberty in males as a cause of epilepsy, contributory or direct, we enter a difficult field, and while the literature on the pernicious effects of masturbation, so common to this period, is copious in the extreme, it is regretably indefinite. In general terms purists charge masturbation with a long list of pathological effects, but generally without specification. To single out this particular vice at a period when important changes little short of revolutionary are being experienced by the entire organism, and lay the gravamen of a specific nervous disorder at its door, is a task requiring great discretion; and one in which mistakes are bound to be made.

Women differ radically from men in the character of the transitional period incident to puberty. In women, it is short, intense, and if the function is properly established, the entire process of passing from girlhood to maturity is quickly over, so if evil is to follow, it usually does so without loss of time. I am speaking now of cases in women in which convulsions appear as the result of some pathological influence incident to the establishment of the menstrual flow.

In males the transitional period is longer drawn out, and it may not reach its maximum of intensity or of completion under several months or even under two or three years. In this single fact we seem to have one reason why the epilepsies incident to the developmental period are often of a graver character, more persistent, more stable, less amenable to treatment, and less likely of cure in males than in females, particularly during the first few years of the disease. After the epilepsy is chronic in either case, the results of treatment show little or no difference.

In discussing the results of onanism we must do so in a calm and discriminative way. Popular literature is full of sensational and drastic statements along this line. As Hall says: "The brain is not literally drained away; dementia, idiocy, and sudden palsy are not imminent, nor is there any peculiarly infallible expression, or attitude, or any other manifestation instantly recognizable by experts."

Being unnatural, the evils of onanism mainly flow from the fact that it requires far greater excitement to produce the same effect as sexual in-

tercourse and, being less dependent on other conditions, it can be practised at will.

In preexisting enfeebled constitutions, the practice, if intensified by excess, brings a train of well defined evils; among them being great mental and physical inertia, palpitation, neurasthenia, spinal neurasthenia, and "a tendency to convulsions." One writer of great repute says: "The onanistic psychosis seems especially to predispose to convulsive disorders like epilepsy, to which it is so akin."

Bachin has described the "masturbatic heart," while Seeley has found a murmur that he thinks is an infallible index of the practice.

Some writers even go so far as to credit excessive masturbation with being a cause of premature senility; early gray hairs, a stooping posture, and baldness being evidences of the practice. Others believe that while its immediate effects may not be disastrous, they may reappear in the offspring in the form of general deterioration and arrest of development.

Gowers thinks masturbation can be properly called a cause of epilepsy only when circumcision relieves the convulsions; but in this I do not agree, for "habit" epilepsy has long been recognized. Spitzka, Clouston, Maudsley, and others speak of "masturbatic insanity," and we at once ask, why not epilepsy as well as insanity?

Among the 1,600 and odd admissions to the Craig Colony up to this time, the assigned cause in scores of the cases coming on in males between the fourteenth and eighteenth years has been set down as due to the effects of masturbation.

I have personally questioned hundreds of boys and young men entering the colony and ascertained that the practice among them is well nigh universal. Only now and then is it denied.

Many young men of fair intelligence assured me that they did not question the fact of some direct relationship between the practice and their epilepsy. But in accepting such statements, I always try to bear in mind that patients who enter the colony do so in the belief that they are taking a final step in the cure of their trouble, and that they are willing to "lay bare" as it were every indiscretion of the past if such revelations seem likely to help them get well.

Under such conditions as these it is easy to let the pendulum of belief in the power of onanism swing too far the other way. Notwithstanding this, I am convinced that cases of epilepsy do arise in males at puberty that are due directly to the effects of excessive masturbation.

I recently saw a young man of 24 years, whose first convulsions came on at 14 years, at which

time and for two years later he practised masturbation to an excessive degree. He quit the practice after three years, but his epileptic attacks have continued. It is only fair to say that he had "some" convulsions when a baby, but they disappeared completely after that to reappear at puberty, apparently under the stress of masturbation.

Briefly summarizing the matter, I believe:

First.—That we can, and must, in many cases of epilepsy, that appear during the twelfth to the sixteenth and eighteenth years, coincident with the establishment of the menstrual flow in women, and with the passing of boyhood into manhood, ascribe to these changes the power of inducing well defined convulsions that may be epileptic.

Second.—That except in the most remote and exceptional instances, these periods alone in normal individuals have no power to induce epilepsy or even epileptoid phenomena.

Third.—That by searching carefully we shall find in most cases of epilepsy at this period, either a previous history of convulsions, usually in infancy, or a family and personal history so tainted with a tendency to disease that epilepsy under the stress of puberty is plainly invited.

SYPHILIS WITH LATE OR ABSENT SECONDARY ERUPTION.*

By ROBERT N. WILLSON, M. D.,

PHILADELPHIA.

Frequent conversations with those who concentrate their attention upon the study of venereal disease (syphilographers so called) regarding the picture that may be held as sufficiently conclusive of the presence of syphilis to warrant the beginning of energetic treatment, have led me to report the following three cases. I have been led to this study first by the discordance between the dictum so urgently laid down by some that treatment should be instituted as soon as the chancre is diagnosed (forgetting entirely the fact that occasionally a primary sore is not apparent), and the equally emphatic assertion of others that the diagnosis often cannot be made at this period.

The second inducement has been the constancy with which the assertions are made that the secondary eruption should be awaited, that it may be confidently expected to make its appearance, that when it is not observed it is overlooked, and that no harm is sustained by the patient during the delay.

All of the foregoing statements I find in a recent article published by one of the occupants of a special chair on venereal diseases in one of the prominent medical colleges of the East. Nearly all,

*Read before the University of Pennsylvania Medical Society, January 20, 1905.

if not all, I believe are to be questioned in the light of my experience in a considerable number of cases similar to three cited at this time.

CASE I.—Mr. X. consulted me in October, 1902. He was a young man 20 years old, previously well and strong. Family history absolutely negative for syphilis, but suggestive of tuberculosis. Patient himself had never before suffered from venereal infection. Two weeks prior to my examination he had been exposed to infection in the usual manner, and twelve days subsequently had begun to notice pain at the head of the penis and a slight discharge. The latter was gradually increasing. He was carefully examined from head to foot, and neither on his penis, his skin surface, nor on the mucous membranes of his mouth could any abrasion, eruption, or initial lesion of any description be discovered. The urethra was examined with the urethroscope and no ulcer could be found, the mucous membrane everywhere being swollen and purple and covered with a profuse purulent discharge, which the microscope showed to contain large numbers of intra- and extracellular gonococci. There was slight tenderness of the inguinal glands of the left side only. Under local and internal treatment the gonorrhœa ran a moderately severe course. During the latter part of December he seemed to be completely rid of shreds and gonococci, and was soon after lost sight of until the following September (nine months later). He then stated that he had exposed himself to infection the second time about three months after being pronounced well by me. This occurred either in March or April, 1903. About the middle of the following June a milky discharge appeared, which soon became thick, yellow and profuse. No blood and no pain appeared. During the entire period (since October, 1902) he had been watching his skin and tongue with strict instructions to report to me at once if even a pimple appeared. He did bring several small acne pustules for inspection, but not an erythematous blush or a macule, or any other suspicious lesion made its appearance.

About the middle of September I examined him, and though he had still the profuse creamy discharge, his cervical glands were enlarged on one side only, the enlargement of the inguinal glands being bilateral. The anterior cervical chain was also palpable; the epitrochlears were not enlarged. The patient stated that for three months he had had a sore throat with enlarged tonsils. In July he was given mercury internally for a few days. The glands became smaller and his throat less painful, but the medicine made him sick and gave him a flushed feeling, and it was then discontinued. He began at the same time by prescription of his physician to use cubebs, and almost at once experienced a profuse eruption "like hives," distributed over the entire body, but with an entire absence of itching. This eruption disappeared almost at once on discontinuing the cubebs, and has not recurred. At the time he also experienced two or three tiny, discrete sores on the glans penis.

When examined by me in September (as stated) the pharynx was red, and over the right arch was a small ulcerous area of erosion. The penis showed a small indurated elevation above the corona, and two small scars at the site of the former sores. The

pus from the urethra was examined, but no gonococci were discovered. On October 5th, however, unmistakable gonococci were found in a few of the pus cells, and in epithelial cells scraped from the urethral wall. No eruption was noted at any point over the skin surface. The patient was then sent to Dr. Grayson, who pronounced his throat lesion probably not syphilitic. It had now been "sore" for four months with no abatement. On October 15th I gave him capsules of sandalwood, belladonna, and morphine, and at the same time a solution of zinc sulphocarbonate for urethral injection. Two days later a typical, coppery (pale) papulosquamous eruption appeared on his palms and soles, itching on the soles only, but each papule slightly tender to palpation. Nowhere else over the body was an erythema, or an eruption of any nature discernible. Prior to this time the patient had been warned of the possibility of syphilis. His medicinal treatment was discontinued at once and the patient sent to Dr. Edward Martin in consultation, the latter concurring in the advisability of discontinuing sandalwood for an indefinite period. He inclined toward the theory of a drug eruption. In spite of a thorough eliminative treatment extending over three weeks, and an absolute cessation of all treatment except in the form of saline laxatives, the eruption persisted without change on the palms and soles and there only. The hair now began to fall freely from the scalp. On November 6, 1903 (one month from the appearance of the palmar eruption), the patient was placed on the protiodide of mercury in increasing daily doses. In three days the outlines of the papules on the hands and feet were less distinct. Within ten days both the palms and soles were normal to all appearances, the angina was distinctly less, and the glands both in the cervical and inguinal regions seemed smaller. One posterior cervical gland, which had enlarged to the size of a pigeon's egg, was softer and much smaller than prior to the beginning of the mercurial treatment.

This case has already been referred to in another paper as one in which only a limited amount of the protiodide of mercury could be used without producing distinct signs of a nephritis. Salivation, tenderness of the gums, or fœtor of the breath on the other hand have never been present. Under careful use of the drug the patient has improved until at the present time, fourteen months from the beginning of treatment, he is entirely free from symptoms, and to one who had not had the opportunity of studying the eruption and the pharyngeal inflammation would appear perfectly well. The sore throat has disappeared, the glands are one by one becoming impalpable, and only the tiny localized area of induration on the glans penis is still in evidence.

CASE II.—Mr. Y., also a young man, 19 years old, was sent to me for examination in June, 1903. There was no pertinent family history, and the patient himself had enjoyed an unusually healthy life. There had been no previous history of venereal infection. Three days prior to my examination he had been exposed, and two days subsequently began to notice a slight burning on micturition and considerable purulent discharge.

On examination the latter was found to contain many gonococci. Three days later he was obliged to be in another city on business and went under the care of another physician. From the latter I learned that ten days after consulting me for the last time, and exactly three weeks after sexual contact, a tiny "sore" appeared near the frenum, from which exuded a milky white discharge. The sore persisted for three weeks, and was pronounced a chancre by the attending physician, though no other symptoms were present. He was treated with large internal doses of mercury during a period of three months, and experienced no bowel or skin disturbances. He had been carefully instructed by me regularly to inspect his body from head to foot, morning and evening, and to report even a suspicion of an eruption. In spite of the precaution no skin lesion could at any time be detected.

He then drifted into the hands of a third physician, who told him he had not syphilis, but that a urethral stricture was the cause of the persistent yellow discharge. He incised and enlarged the meatus and passed full sized sounds.

In November, 1903, the patient again consulted me, having at this time no symptoms other than a persistent sore throat, and the constant, fairly profuse urethral discharge. On the penis could be detected a tiny induration at the site of the original sore. There was no eruption to be noted at any point on the body surface, there was no glandular enlargement (except of a usual degree in the inguinal region), and at no time could gonococci be detected in the urethral pus. The urethra admitted a No. 28 and later a No. 30 French sound, though with some difficulty. Certainly there was no marked contraction of the passage. He was advised that syphilis was possible, but that no one could formulate a definite diagnosis at that time. I advised against the use of mercury. In January, 1904, his hair began to fall profusely, and one small pimple appeared on his scalp. There remained now merely a moisture at the urethral orifice. The pharynx was still red and angry and the angina constant. The only palpable glands were in the inguinal region; the epitrochlears and postcervical chains could not be demonstrated.

In consultation with Dr. J. William White it was decided to use mercury experimentally, the urine being absolutely normal and the patient in good condition. The protiodide was given in ascending doses. Within ten days, when taking two thirds of a grain three times a day, the sore throat had almost disappeared, the pharynx was much less congested, and the patient showed no sign of salivation or mercurial intoxication.

Prior to June, 1904, there had been no possibility of an overlooked eruption, excepting the single "pimple" on the scalp six months after the last exposure. Suddenly, and while still under constant mercurial treatment (protiodide, half a grain, thrice daily) he began to feel "mean all over just as last year," the pharynx became red and painful, and a profuse pink, macular eruption appeared over the entire body, excepting the face, the legs being especially affected. This persisted for two days and then disappeared. The patient

attributed the occurrence to the ingestion of strawberries, although he had eaten them in quantity before and has many times since without untoward effect. This occurrence was one year after the last exposure to venereal infection. The patient is still using half grain doses of mercury three times daily, and finds that two thirds of a grain produces intestinal irritation, headache, backache, etc. His skin has remained absolutely clear, the mucous membrane of the pharynx appears normal, hair has ceased falling, and only the indurated scar on the penis remains.

CASE III.—Mr. Z. presents a still more interesting history than the preceding, because not only was the opportunity afforded for a confirmation of the otherwise doubtful diagnosis of latent syphilis, but such a routine and persistent study has been made of the skin as to afford no opportunity for error in the statement that an eruption has never appeared. The patient was infected with syphilis seven years ago. In brief the history was as follows. A young man of 20 years of age was exposed to infection, and ran the usual course of a fairly severe gonorrhœa, gonococci being found in large numbers in the urethral pus. A unilateral epididymitis was followed by a general glandular enlargement, including the inguinal, axillary, epitrochlear, anterior and posterior cervical, and the anterior and posterior aural series. Tiny kernels could also be palpated above the ramus of the jaw, each of these being surrounded by an area of slight tenderness. No lesion other than that of gonorrhœa could be discovered in the urethra, the pharynx, or on the skin surface. The patient became entirely well subjectively, but a slight moisture persisted in the urethral meatus, and the glandular enlargement showed no tendency to subside. It was thought possible that the latter might be due to a general gonococcus infection, though no other sign could be detected to substantiate that view. The discharge disappeared excepting a morning drop of thin mucus, which resisted all treatment, including dilatation of the passage. Up to this time and daily for over one year from the time of the original infection the patient was inspected from head to foot, and no new explanation of the persistent glandular enlargement and the urethral catarrh could be found. The glands were indurated, painless, the pharynx negative, there was no alopecia, and on no occasion could there be detected the slightest erythema or eruption of any nature. From that time until about a year ago he has been well and strong, though his hair has gradually fallen, until he is now decidedly bald. One year ago it was noticed by him that he was having considerable sore throat, was a little husky at times, and his collar began to be uncomfortable where it pressed upon the back of his neck. Later on he had vague pains in the joints which he thought were gouty, and finally he came to me for advice. He stated that during the six years since I had seen him last he had kept constant watch upon his skin surface, and had never had the slightest eruption, excepting an occasional pimple upon his face. About a year ago he had a few "crusty pimples" in his hair, which later en-

tirely disappeared. His sore throat had persisted now, however, for nearly a year. He remembered that once during the last year he had had a few pimples upon his palms, which after a few days "peeled off" and disappeared.

On examination I found merely a red, congested pharynx, no mucous patches, no sign of an indurated scar either on the penis or in the mouth. The glands were still enlarged and indurated, and as far as could be recollected, very similar to those palpated six years previously. On pressure over the postcervical chains the patient felt a dull ache, evidently corresponding to the pressure pain caused by the collar. There was no eruption upon the face or body.

There seemed to be no doubt that mercury should be employed empirically. The prompt and grafting result of a few weeks' treatment with protiodide alone rendered almost certain the conclusion that the original infection had been a double one of gonorrhœa and syphilis. About a month later the wife of the patient gave birth to an unmistakably syphilitic child, which fortunately did not live to fight for health and existence against the odds placed in its way by the father's error. The mother even to-day shows no trace of syphilitic contamination.

In reviewing these cases I cannot believe them to be wholly unusual, even though they controvert, in many respects, the prevailing tenets and teaching with regard to the symptoms and course of the disease. It rather appears to me that a form of syphilis exists in the better classes (and sometimes, though more rarely also in the poorly nourished) which we have been slow to recognize, and which it behooves us to study for the sake of posterity. There is little likelihood, in the first place, that in any of these cases there still exists a doubt as to the accuracy of the diagnosis of syphilis. Cases I and III, eventually gave unmistakable, and Case III the most doleful of all positive signs that can be obtained. Case II presented a possible primary lesion, but at no time a secondary skin eruption, and yet there is little room for doubt as to the condition under treatment.

If we analyze the histories, we have in Case I: Undoubted syphilis, an indefinite primary lesion (chancere), a typical gonorrhœa (gonococci present in large numbers), an entire absence of early secondary syphilitic lesions, a possibly syphilitic eruption synchronous in its appearance with the use of cubebs four months after the last exposure, and disappearing at once on discontinuing the drug, finally a syphilitic palmar and plantar eruption seven months after the latest possible date of infection. The case responded at once to mercurial treatment. Case II: Gonorrhœa, a probable primary lesion of syphilis on the penis, with induration remaining, and wide but atypical distribution of the glandular enlargement. Sore throat, malaise, alopecia lasting for a month and controlled promptly by mercurial treatment; an entire absence of a secondary eruption to date;

occasional exacerbations of throat and systemic symptoms. Case III: Undoubted syphilis with gonorrhœa; general glandular enlargement; entire absence of (or failure to discover) a primary lesion; entire absence of secondary eruption during the first five years of the disease; then sore throat, alopecia, palmar and plantar papulosquamous eruption, and subsequently the birth of a syphilitic child.

In the light of the foregoing what must we say to certain critical and rather cynical friends who scoff at the possibility of syphilis in the absence of an early skin eruption, i. e., such as may be expected within the period during which we can justifiably postpone treatment? First of all we must define for ourselves this word "reasonably." Christian (*Therap. Gaz.*, June, 1904) in describing the different clinical forms of the disease cites two types in which the skin eruptions always appear "at the proper time," i. e., "six or seven weeks" after the primary infection. In his "third type" he also mentions a rash, but gives no time for its appearance. Presumably this is early, however, as it is accompanied (he says) by all the symptoms which are considered the rule rather than the exception in a severe infection. In his discussion of a query with regard to the very point under consideration in this paper he made the statement (*Phila. Co. Med. Soc.*) also that "he cannot conceive of a case of syphilis without a secondary eruption." Other authorities take the same ground or beg the question. All seem to believe that a careful search will be rewarded by the discovery of the eruption soon or later. Evidently, however, if the eruption is late in appearing, each man must set an arbitrary time for the institution of mercurial treatment, and the tendency will be to postpone that time as long as one can be sure, from his own experience and that of others, that he is safe in diagnostic procrastination. Otherwise he is compelled for conscience's sake to disregard the eruption entirely and study his case as if a skin lesion were unlikely rather than probable.

My own feeling upon the question is somewhat as follows: If the poison of syphilis is systemic in its action, as we know it to be, a postponement even of days insures a more radical and thorough infection of the tissues. I do not believe that a case which has remained untreated for six weeks or three months presents as simple a problem (all other things being equal, such as individual susceptibility, etc.) as one that is treated from the first days or weeks, if we must wait weeks, of the disease. I believe, moreover, that the day will come when we shall realize that the earlier syphilis is treated, the more likely its cure; and that

this will lead perhaps to the discovery of a local and general prophylactic treatment instituted invariably immediately after illegitimate intercourse. In any event, there seems to me to be no justification, since cases occur such as are here described, for a delay even in doubtful instances one day longer than the customary six weeks from the time of exposure, provided a suspicious primary sore has been observed or a general glandular enlargement or persistent fever, or an increasing leucocytosis, or any of the signs suggestive of the disease. We have placed before us the choice between an untreated syphilis and a long course of unnecessary treatment, and for me the latter is preferable.

An attempt has recently been made in several of the large institutions of learning of this country, and especially in the University of Pennsylvania, to advise the students of the dangers involved in illicit intercourse. The endeavor has evoked from a small, but energetic number of genitourinary specialists the complaint that "ultrapessimism" regarding venereal disease has become rife among the medical profession, and through them among the laity. The reply might well be made that in spite of their ministrations, and ours, the blind asylums and the rapidly increasing sterility of our race are a portion of the tribute we pay to gonorrhœa, while the price exacted by our indulgence in syphilis is too grave and too various to be reckoned. I am confident that both gonorrhœa and syphilis are on the increase, the latter in a less malignant and repulsive, and, therefore, more dangerous form. This statement cannot be truly made of any other infectious disease in this portion of the world. It may well be that the spread of syphilis is partially due to the unrecognized and untreated cases, many of them in the negro, in which the supposedly invariable skin lesion has appeared very late or not at all. The day will come in which both gonorrhœa and syphilis will be classed and treated as contagious affections, reportable and isolable; and the unfortunate certainty that one of the reliable early signs of the, perhaps, more deeply rooted disease of the two can no longer be regarded as infallible, will serve to point to prevention as a logical and imperative measure.

Ohio Pædiatric Society.—The Ohio Pædiatric Society closed its convention at Columbus, on May 9th, and elected the following officers: President, Dr. William Clark, of Cleveland; first vice-president, Dr. Frank Winders, of Columbus; second vice-president, Dr. Hugh E. Lorimer, of Jamestown; secretary and treasurer, Dr. Gilbert L. Bailey, of Cincinnati.

THE RECOGNITION AND DIFFERENTIATION OF RÂLES IN THE LUNG.*

By FREDERICK E. BEAL, M. D.,

NEW YORK,

LECTURER ON PHYSICAL DIAGNOSIS, NEW YORK POLYCLINIC SCHOOL AND HOSPITAL; ATTENDING PHYSICIAN, NORTH-WESTERN DISPENSARY, ETC.

I consider a simpler classification of râles, as heard in the lung, of sufficient importance to be the subject of this brief paper. I have been led to this belief by my own inability in the past properly to identify and classify the various râles I have heard in the chest under the names used in the textbooks. I find, since coming in closer contact with practitioners during my connection with this institution, that others have the same difficulty; and it is not infrequent to hear a sharp discussion between men of marked ability as to the name of a râle and the class to which it belongs, though it may have been equally well heard by each. All this, in my judgment, is owing to a great extent to the confusing nomenclature employed by writers in classifying râles.

I wish to say that in my opinion the râles heard in the lung should be divided into but two divisions; dry and moist; and that it is as possible, and easily possible, to differentiate between a dry and a moist râle as it is to tell the difference between the sound of a piano and that of a violin. I appreciate fully the scope of this assertion, and shall not be surprised if it meets with prompt and vigorous denial, but I beg leave to repeat that it is perfectly possible instantly and with certainty to recognize either of the two kinds of râles heard in the lung.

It is true that a dry râle may vary in its size from that produced by the largest bronchus to one having its origin in the tiniest bronchiole; while the size of the moist râle may be that of the finest air vesicle to that of the largest cavity, and the number of râles, each of different size that could possibly exist between these extremes is almost without limit. Then why should we confuse ourselves by picking out two or three of each kind and give these the dignity of a name, dubbing them crepitant, subcrepitant, sibilant, or sonorous? It is enough to know, and it is of the greatest importance from a diagnostic and prognostic standpoint, that a râle is dry or moist; and this can with certainty be known while its size though important can be told with a moderate degree of accuracy by its pitch.

The great point of distinction between a dry and a moist râle is simply this: a dry râle has always some duration, while a moist râle is always *instantaneous*. By looking a little into the causes of these râles, I think I can prove my premises. A

* Read before the Clinical Society of the New York Polyclinic Medical School and Hospital.

dry râle is caused by air going at a given rate of speed through a smaller sized tube than it normally does, thereby raising the pitch of the sound produced, on the same principle that we pucker our lips to whistle, instead of opening our mouths widely. At a glance one can see the commoner causes of dry râles: mucus stuck so tenaciously on the side of the bronchus that the breathing does not move it will lessen the calibre of that bronchus; any condition, acute or chronic, that would thicken the lining membrane of the bronchus; any pressure from without, or any foreign body or growth within that would encroach upon the size of the air passage; and, finally, any nervous phenomenon that would spasmodically cause the bronchi to lessen their calibre would give rise to the same condition. In any case, you will notice that the adventitious sound produced must and *does* possess some prolongation or duration, and its pitch or size may be from the loud, large, stertorous breathing of the dying to the very high, fine, hairlike whistlings heard in the bronchial pneumonia of the infant.

The moist râle, on the other hand, is caused in one of two ways: either by the pulling apart of moist, adhering surfaces, or by air passing through an accumulation of fluid that is sufficiently liquid to allow it to bubble through. Its size may be caused by the breaking apart of the adhering surfaces of the finest air vesicle or to that of the pulling apart of the walls of a collapsible cavity; or the air may break through a collection of thin mucus filling a bronchus; or, again, a cavity may be more or less filled with fluid, and entered below the surface of that fluid by a bronchus. The air entering through the bronchus will bubble up through the liquid, but the sound produced will always be instantaneous, as may be proved by blowing through a rubber tube that is inserted to the bottom of a vessel filled with water. It will be noticed that no matter how steadily the air is forced through the tube, its breaking to the surface of the water will be by a series of bubbles or gurgles, each instantaneous in character. I deem it almost superfluous to state that while the sound produced by the fine air vesicle and that of the cavity whose walls collapse at each expiration, are both instantaneous, yet there is, technically speaking, some apparent difference in their duration; on the same principle that the duration of the sound produced by the discharge of a twelve inch rifle is greater than that produced by a paper cap pistol, yet the brevity of the former is surely infinitely greater than the latter.

I cannot approach the various pathological conditions in which these two râles are pathognomonic, but will only say that, very broadly speaking, the moist râles are of far graver significance than are

the dry. The dry râles, or those with duration, are the whistlings heard perhaps in their greatest profusion and purity in bronchitis, more especially chronic, emphysema, and asthma; while the moist râles, or the clicking, crackling, snapping sounds without duration, are most typical in pneumonia and tuberculosis pulmonalis. To the latter disease, especially, would I most earnestly call attention, for it is here, in its earliest stages, and while there is yet every hope of successful therapy, that we hear on deep inspiration the little, fine, hairlike cracklings, instantaneous in character, which may be so easily overlooked or mistaken for the rubbing of the hair against the examiner's ear, but which tell, as loudly as they can, the beginning invasion of the tubercle bacillus.

76 WEST EIGHTY-FIFTH STREET.

ALKALINE BEVERAGES IN THE TREATMENT OF PNEUMONIA.

By J. B. TODD, M. D.,

SYRACUSE, N. Y.

This is an attempt, first, to interpret the clinical history of pneumonia, viewing the *Micrococcus lanceolatus* as the source of infection, and the clinical phenomena as the expression of the biological life of the germ in the structures involved, and, second, to illustrate the therapeutical value of alkaline beverages when employed from the inception of the disease.

Sternberg (1) has found the pneumococcus in the saliva and nasal secretions in a large percentage of persons in health. To arrive at a proper understanding of the manner of pulmonary infection, it will be necessary to consider the life history of this germ.

Sternberg (2) states also that "the pneumococcus grows at temperature from 60° up, and at 104° growth ceases. It grows best at temperature of from 91° to 98°, and grows very rapidly in a suitable medium. Its growth requires a slightly alkaline medium, but will not develop in a medium which contains the slightest trace of acid. In infusions made of chicken or rabbit it multiplies in the incubating oven with remarkable rapidity. At the end of from six to eight hours after inoculation, the infusion, previously a clear fluid, will be found to present a slight cloudiness, and to be filled throughout with cocci in pairs and short chains. Multiplication ceases at the end of about forty-eight hours, and the liquid medium again becomes transparent, as the result of subsidence of the cocci to the bottom of the receptacle."

It is evident that the alkaline blood serum furnishes an ideal medium for their growth, but that

the normal temperature of the blood is a little too high to favor their development. It is also necessary that the vitality of the body be slightly impaired, as from overexertion, or breathing impure air, or exposure, that the body temperature be temporarily lowered in a slight degree; then the conditions are favorable for the infection. There is a range of from two to three degrees in the temperature of persons in health. I have observed a temperature of 97° in a person who had been working hard for three hours. In this case the fatigue was manifest by pallor and subjective sensations of hunger, but after a rest of half an hour and immediately after a meal it rose to 99° . The body heat being largely produced from the glycogen stored in the muscles, the exhaustion of glycogen, Latimer (3) shows is manifest by the sensations of fatigue. This also explains why alcoholics are more vulnerable to the disease, as they are more liable to have the subnormal temperature necessary for the infection.

Referring to the subnormal temperature in alcoholics, Schaffer (4) states that "various observers have found alcohol taken in ordinary quantities as a beverage caused a slight depression, generally less than half a degree, in the temperature of healthy men; on the other hand, poisonous doses may cause a fall of five or six degrees."

Infection probably occurs prior to the chill, which undoubtedly marks the moment of systemic toxæmia, and may be accompanied by an actual elevation of temperature. Immunity from infection possessed by persons in health is maintained by two factors, first, the normally high temperature of the blood. Flint (5) says "the temperature in the blood of the hepatic . . . ranged from 101° to 107° . In the aorta it ranged from 99° to 105° ." This temperature is necessary to maintain the protective efficiency of the enzyme, variously called by different authors, but which Sajous (6) furnishes good evidence to be trypsin, and, second, by the much lower temperature in which the micrococcus best grows, *i. e.*, from 90° to 98° .

The classic symptoms of a case of pneumonia are, we know, high temperature, characteristic cough, rusty sputum, dyspnoea, right heart more or less engorged, urine scanty and of high specific gravity. Everything points to intense toxæmia and increased cellular metabolism.

The infection occurs in the air cell. Piersol (7) describes an air cell as consisting of epithelium, connective tissue, and capillary net work. The infection having occurred in the epithelium, Foster (8) outlines the sequence of events partly as follows: The white corpuscles congregate in

the area of irritation, each one exhibiting a tendency to stick to the sides of the vessels. The white corpuscles, lying in contact with the walls of the veins or capillaries, are seen to thrust processes through the walls, the process of a corpuscle increasing at the expense of the body of the corpuscles, and making its way through the wall of the vessel into the lymph space outside. Through this migration the lymph spaces around the vessels in the inflamed area become crowded with white corpuscles. At the same time the lymph in the same spaces not only increases in amount, but changes its chemical character, becomes more coaguable, and is spoken of by older writers as coaguable lymph.

This condition probably corresponds to the stage of congestion, but as the process goes on and the lymph spaces and capillaries become more and more crowded, there is an actual giving away of the capillary wall, and the red cells escape forming the stage of red hepatization. In all of this there is probably nothing absolutely peculiar, or specific, to the disease; it represents an effort of the white cells to "wall off" and surround any infection. The histological character of the structure involved determines the result, however, the crowding of the white cells tending only to fill the lymph spaces first and, finally by distention, the air cells.

While these changes are occurring in the air cells, there is an elevation of temperature from 102° to 105° , or even higher. The leucocytes are greatly increased. Anders (9) says in this connection: "Slight leucocytosis may indicate a mild infection; leucopenia occurs in the malignant cases, on the other hand, leucocytosis of high degree, while indicating a severe infection, also shows a good reaction." Again, "the urine is scanty, high colored, and acid. The absence of chlorides is of little diagnostic value."

The high temperature and leucocytosis indicate intense reaction from the infection, but this reaction consists of cell change, *i. e.*, cellular metabolism, which tends to reduce the alkalinity of the blood.

Any theory of heart failure falls short unless it takes into consideration all the existing conditions. To say overdilatation of the right heart, and that retarded pulmonary circulation are the causes, is only a partial statement. We should have a clear conception of the normal blood as a living stream, faintly alkaline, with its life sustaining salts, holding the fibrin in solution, and filled with living cells upon whose functional activity depends the life of the patient. We should thoroughly appreciate that this life blood exists

in a state of unstable equilibrium (10). Toxæmia with its increased cellular activity very rapidly produces changes in the biochemical constituents of the blood and tissue plasma. Increased metabolism means increased oxidation, which means consumption of the alkaline salts. The blood gradually loses its alkaline salts, begins to have a tendency to precipitate its fibrin by reason of its increased specific gravity, and at the same time the toxins accumulate in sufficient amount to entail cardiac arrest. Green (11) says: "Exhaustion as applied to the heart expresses states in which inorganic salts necessary to the contractions of the heart are removed or disturbed, or it expresses states in which the antecedent organic contractile material is consumed or removed."

Sajous (12) referring to experiments *in vitro*, but the results of which he deems applicable to pathogenic elements and their toxins, says: "Another result of the want of normal amount of alkaline salts in the blood plasma is an interference of the function of the leucocytes. Trypsin acts only in the presence of salts, and soon loses its hæmolytic power when relieved of them." Sajous also states: "The relatively enormous excess of leucocytes which invade the lungs during the first stage of this disease necessarily involves the use of a correspondingly great quantity of these salts, the nucleins and trypsin soon appropriating all those available."

Intrinsic metabolism is impaired through deficiency of any of the molecular constituents of the blood. Foster (13) says: "The corpuscles with which the blood is crowded are living structures and consequently are continually acting upon and being acted upon by the plasma," and also that "the blood . . . is in a state of unstable equilibrium."

Now, as stated by Sajous (14), "All the alkaline salts referred to are ingested with foods or beverages. During disease, on the other hand, the restricted or modified diet involves a marked reduction in the amount of alkaline salts ingested." "It becomes evident," adds the author, "that a morbid cycle exists in this connection, pernicious in the extreme to the welfare of the patient because the source of these salts being external to the system, the latter is possessed of no intrinsic reserve. Steadily as the febrile process advances, the alkaline salts are consumed, and being inadequately renewed, the vital and defensive functions are unceasingly hampered until life ceases."

A typical case goes on from four to eight days when there is a fall of temperature and generally a relief of all the distressing symptoms. Can this crisis be satisfactorily explained?

A careful consideration of the biology of the pneumococcus in its environment will account, it seems to me, for all the phenomena.

The pneumococcus grows at a temperature of from 60° to 98°, but especially thrives from 92° to 98°. At 104° it ceases to multiply. It requires an alkaline medium. Sternberg (15) found that at 104° they were all dead in two days. It is plain, therefore, that when the proper specific gravity and alkalinity of the blood are maintained, a temperature of at least 104° for a certain time inhibits the growth of the pneumococci. When these germs cease to multiply the phagocytes are able to destroy the cocci and their toxins, and the case results in a crisis.

Thus it will be seen that when the specific gravity and the alkalinity of the blood are adequately sustained, a relatively high temperature inhibits the growth of the pneumococcus and precipitates the crisis. In cases of recovery by lysis, the leucocytic reaction has probably been sufficient to overcome the pneumococcus before sufficient time has elapsed with a temperature of 104° to inhibit their growth.

With this view of the biology of the pneumococcus in mind the writer has treated all cases of pneumonia for the past two years with salines. At first they were used per rectum, as suggested by Dr. F. P. Henry, of Philadelphia, in 1889. But it seemed unnecessary to give saline solutions by the rectum, when they could be taken by the stomach, so the latter method of administration was adopted.

Various prominent authors recommend subcutaneous or intravenous injections to prevent heart failure. Cohen (16) says: "Pneumotoxine so alters the chemical relations of the blood as to favor coagulation processes," and he also speaks of the "philosophic justification of the modern use of saline solutions." It would seem more philosophical to preserve the molecular constituents of the blood from the very beginning of the disease and not to allow its equilibrium to be disturbed. Broca and Richet, as quoted by Budgett (17), says that the injurious effects of lack of oxygen which they observed were due to the toxic action of unoxidized waste products. In the complete toxæmia and impaired alkalinity of the blood, the phagocyte and patient are both involved in the common ruin, the final death of the phagocytes precipitating saturation toxæmia commonly spoken of as heart failure.

Most authors do not attach any great importance to the character of the urine. If I interpret the matter correctly the urine is almost a complete index to the case.

In the augmented cellular reaction, which is

evidenced by the high temperature, intense thirst, and increased leucocytosis, the salts of the blood plasma are soon exhausted, as is also the intercellular fluid of the body. All this is very evident by the scanty, high colored urine and the absence of chlorides; the blood plasma and cells have their supply exhausted. This condition is all changed when salines are given from the first; six or eight ounces of saline solution every two hours, and all the water the patient wants besides. The urine continues light colored, profuse in amount, three to five pints in twenty-four hours, and is less acid.

A profuse, light colored urine indicates that the blood salts and fluids are being conserved; that the conditions are favorable to the life of the leucocytes, and that cutaneous, pulmonary, and renal excretions are not retained; while a scanty, high colored urine indicates the reverse, the toxic material being retained in the system until the heart cannot work under the burden.

A rational consideration of the various conditions that are grouped together to make up the disease called pneumonia, brings the inevitable conclusion that in the treatment of the disease we should do all in our power to promote leucocytosis through the entire course of the disease, also to preserve the proper alkalinity of the blood, for upon this depend the functional life and activity of its living cells to perform their work of growth, repair, and also of the removal of waste products, and destruction of the bacteria and their toxins. We should also maintain the normal specific gravity of the blood. When the tissue and blood plasma are reduced in amount, that remaining is increased in density by being overloaded with waste products; the movements of the amoeboid cells are hampered, even the integrity of the red cell is impaired. The hæmoglobin change to oxyhæmoglobin is retarded.

All these requirements are accomplished by the administration of alkaline saline drinks from the inception of the disease, and during its entire course. Of a solution of two and one half grains of sodium chloride and one grain of potassium bicarbonate to the ounce of cold water, from six to eight ounces should be given every two hours. The addition of a teaspoonful of lemon juice converts it into a refreshing effervescent drink, which is gratefully accepted by the patient. Besides this drink the patient should be allowed all the pure water desired. A well lighted room at a temperature of 55° to 65°, with an open window, so the patient can have an abundance of oxygen from Nature's storehouse. The patient should be generously fed every three hours, and the best and most nutritious foods are milk, eggs, and bread.

How can we know the alkalinity and specific gravity of the blood are being maintained under this treatment? The alkalinity can be tested by putting a drop of blood on glazed litmus paper that is just neutral in reaction. If the blood drop is brushed off in a moment the color will indicate the reaction. The specific gravity can be ascertained by the benzol-chloroform test, yet we have a more trustworthy and convenient index in the urine. When this treatment is maintained the urine amounts to from forty to eighty ounces in twenty-four hours, is light colored, and has an abundance of chlorides. If the urine becomes scanty and high colored, the alkaline saline draught should be increased in amount or frequency. Scanty, colored urine indicates tissue drought, and increased specific gravity of blood; light colored, profuse urine the reverse.

The administration of alcohol, strychnine, and the so called heart tonics to sustain a heart nourished by blood, altered in its biochemical constituents and by toxins, is analogous to sustaining a starved horse with a whip when he fails to draw his load.

I would, however, not be understood as condemning these valuable remedies when needed, but in my personal experience there has been no occasion for their use.

The following is a report of two cases:

CASE I.—Mrs. C., aged 84 years, widow, previous health good. She was remarkably vigorous and active for one of her age. December 29, 1903, she had a chill. I saw her the next day for the first time, when she had a temperature of 104°, with the characteristic cough of pneumonia, although the physical signs were negative until the fourth day, when the upper right lobe became dull. She was given saline drinks from the beginning, two and one half grains of sodium chloride every hour in from three to six ounces of water. The temperature fluctuated from 102.5° to 103.5° for four days, then gradually declined to normal on the eighth day of the disease; the rusty sputum was first seen on the fourth day. She was troubled with insomnia, which was relieved by giving bromide of potassium. She was fed liberally with milk, eggs, and bread. This case terminated by lysis, and in three weeks the patient had regained her strength sufficiently to be able to get about the house.

CASE II, that of Ada C., aged 8 years, is interesting, because the ætiology can be traced to the breaking down of the ventilating fan in one of the city schools, thus allowing the school room to be filled with body exhalations and carbonic acid. After being exposed to these conditions for two days, she became ill, and the second day, December 21, 1904, I saw her for the first time. Her temperature was 103.5°, pain in arm and body, slight suppressed cough, nausea, and vomiting; the infection was in the lower lobe of the right

lung, and by reflex irritation communicated to the stomach through the diaphragm; the nausea continued until the third day. During this time saline infusions were given per rectum, but were not completely retained; the urine was becoming scanty and high colored. The nausea having passed away, she was put on effervescent saline drinks. This is the formula used:

℞ Sodium chloride.....320 grains;
Potassium bicarbonate.....160 grains;
Aromatic fluid extract (U. S. P.).....30 minims;
Water enough to make.....4 ounces.

M. Teaspoonful in six to eight ounces of water every two hours with a teaspoonful of lemon juice.

For two days she had severe headache, which would be relieved in a short time by the ice cap.

As soon as she began to take the saline drink the urine increased in quantity until on the sixth day, she voided 66 ounces, although her temperature was from 103.5° to 104°. She was given milk, eggs, and milk toast, and all the cold water she wanted, which was a swallow every ten or fifteen minutes, when she was not sleeping. The rooms were kept at a temperature of from 55° to 60°, with a window open all the time. The cough, while persistent, was not troublesome; camphorated oil was applied to chest, which was covered with a cotton jacket. There was no expectation of anything during the entire course of the disease, and her tongue was clean and moist. The crisis occurred on the eighth day, and her recovery was rapid and uneventful from that time.

The micrococcus being the infecting germ, and the maximum temperature favoring its growth being lower than the internal body temperature, predisposing causes become interpreted as conditions which produce subnormal temperature. The infection having occurred, the exudate is due simply to "wall off" efforts of the white cells, while the toxins increase the temperature sufficiently to inhibit the micrococcus. But this temperature reaction tends to alter the specific gravity and alkalinity of the blood, which interferes with the functions of the leucocytes, and also prevents elimination of toxine and tissue waste, thus allowing them to accumulate in the system until they react upon the heart and produce cardiac arrest.

The basis of rational treatment consists in preserving the integrity of the blood from the inception of the disease by administering saline drinks, the proper condition of the blood being approximately indicated by the kidneys secreting a large quantity of urine; and, besides, in maintaining the integrity of the blood as indicated, and symptomatically treating such conditions as may arise in any particular case.

THE VIRGINIA LAWS REGULATING THE SALE OF POISONS.*

By GEORGE E. BARKSDALE, M. D.,

RICHMOND, VA.

The subject that I present for your consideration is fully worthy of far more time and deliberate thought than it has received during the past; for until we are brought to a consciousness of what harm the careless sale and handling of potent substances are doing, it is hardly likely that we shall give the matter great thought.

For two or three years I have been at great pains to elaborate a bill that would be sufficiently stringent in its provisions to protect the public, yet permitting with the least degree of inconvenience the dispensing of poisonous drugs without unduly making the provisions irksome. I have read the draft of this proposed bill before the Virginia Pharmaceutical Association, where it caused a great stir and precipitated a heated discussion; but no action was taken other than referring the paper to a committee, and my effort, as well as that of others, fell flat; nothing was done.

I did likewise before the Richmond Academy of Medicine and Surgery and had the good fortune to secure that society's approval and indorsement of my bill.

Now I have come to the chief of all medical associations in Virginia to secure its indorsement likewise. When I have fully given my reasons for your approval and support to have my bill become a law, I do not think you will deny it.

The United States Vital Statistics for 1900 give the total number of deaths in Virginia for that year as having been 25,252. Of this number 110 were due to drowning, 57 to murder, 18 to injuries due

* Presented at the meeting of the Medical Society of Virginia at the meeting in Richmond, Va., October 18 to 22, 1904.

to machinery, 14 to lightning, 37 to burns and scalds, 132 to railway accidents, and 59 to poison alone! More than one half as many as were drowned, more than were murdered, more than three times the number that were killed by machinery, and about half the number killed by railway accidents. Of the suicides occurring within the State, which numbered a total of 27, 2 were from throat cutting, 2 from drowning, 3 from hanging, 4 from poisons, and 16 from shooting. Thus we see that 55 persons lost their lives from accidental poisoning in a single year within the State.

When we consider that almost as many persons lose their lives owing to poisons as die from the accidents of pregnancy, including sepsis and eclampsia, upon the latter of which we have a surfeit of papers and discussions annually, it is assuredly time for the law to adopt some means to withhold from a public that is ignorant these dangerous drugs.

Of course, it is not meant to prohibit the sale of poison, that would be well nigh impossible, but rather to limit the sale and to hedge about the innocent user with proper safeguards that will, I ardently hope, lessen this flagrant waste of life. At present there is virtually no poison law upon the statute books. We read of such nonsense as this, I quote from Sec. 1763 of the code:

"It shall not be lawful for any person, having authority to sell or dispense medicines or poisons, to retail, except upon prescriptions of a regularly licensed physician, dentist, or veterinary surgeon, morphine and its preparations, opium and its preparations containing a higher percentum of opium than laudanum, prepared in accordance with the formula of the Pharmacopœia of the United States of America, and the druggist shall take and file and not refill the same; nor such person, or persons, retail any poison enumerated in the following schedules 'A' and 'B' without distinctly labeling the bottle, box, vessel, or paper, in which said poison is contained with the name of the article, the word 'poison,' and the name and place of business of the seller; and in addition thereto at least two of the most readily obtainable effective antidotes to such poisonous article."

This could be construed to mean almost anything. It prohibits the selling of ten grains of morphine except upon a physician's prescription, but allows the wholesaling of a phial containing a drachm! It allows the sale of laudanum and forbids the apothecary to sell opium and extracts of opium. Yet gallons of laudanum are sold to a pound of the crude opium. The accomplished pharmacist who can discriminate is forbidden to fill a prescription which contains extract of opium or morphine, yet the country merchant who is ignorant of medicine can sell as much morphine as he pleases.

For reasons best known to the original author

of the poison law, which, by the way, is virtually a copy of the poison law of some other States, it has been thought necessary to divide poisons into two schedules, namely, "A" and "B." The reason for this has never made itself apparent to me and is as senseless as it is useless.

"Schedule A" embraces the following: Arsenic and its preparations, corrosive sublimate, biniodide of mercury, cyanide of potassium, hydrocyanic acid, strychnine and its salts, and essential oil of bitter almonds."

These poisons are to be registered, but aconite may be sold without registration. Will anybody be so bold as to say that an ounce of tincture of aconite will not produce death as well as one of Fowler's solution? Or is not red precipitate (which it is not necessary to register) quite as potent as biniodide of mercury? Does anybody seek to murder or commit suicide with strychnine, when carbolic acid or opium is readily obtainable? Assuredly *no*. Yet strychnine must be registered and opium need not.

This law further prescribes that no cocaine shall be sold other than by a regularly licensed pharmacist, and his sales are restricted to physicians, surgeons, dentists, and pharmacists. Is cocaine worse than opium? In this brief summary of the poison law of the State we have reason to see that we have grown negligent in the matter and it badly needs attention. Powerful agents that are likely to produce permanent injury or loss of life are easily obtained and with the inevitable result. Ignorant persons deeming themselves immune to large doses take them and death results. Children secure bottles of poisonous tablets and eat them—the same result. Poison bottles being like other kinds, mistakes are made in the dark and the wrong substance taken, causing lasting regret—but again a like result. Then the hapless suicide, perhaps a drunkard after a night of wassail, tottering upon the verge of madness, takes poison and leaves a family dependent upon the State. This may seem funny to some, and I have heard many jeer that it is well to let a suicide die. But, while I possess a supreme sense of the ridiculous, the point of this joke is lost upon me.

Now, since there is no poison law that we can depend upon with confidence, I shall go into a discussion of the one I propose. First, let us suppose that there is not a single regulation governing the sale of poison in the State, or in the Union; it would be necessary to define the term poison or to name the lists of substances so considered. Now, since some poisons are more potent and rarer than others, these have been placed in a separate paragraph, and are positively forbidden to be sold except upon the order of a physician.

The less poisonous substances are placed in another paragraph and are forbidden to be sold in quantities of over a drachm of the drug, or a fluid drachm of the liquid or solid preparation thereof, or more than a quarter of an ounce of croton oil, chloroform, chloral, sulphate of zinc, or carbolic acid to be sold except upon the written order of an officer of the law, a physician, veterinary surgeon, dentist, or analytical chemist.

Why this restriction? This is why: Persons suffering from acute pain can find relief probably by using a drachm of laudanum, but it is hardly likely to produce death, at least there is not the likelihood of its doing so that there would have been had an unlimited amount of poison been obtainable.

The quantity of chloroform, croton oil, etc., is limited for the very same reason. Should the person desire more, it would be necessary to make the facts known to a third person, and to secure his consent in writing.

All of us know how frequently murderers have been trapped by means of the records of poisons kept in stores; and we also know that even the lax surveillance that has been hitherto observed in the sale of poisons has had the tendency to materially lessen the number of murders that have been committed by means of them.

The writer considers it nothing less than criminal to dispense a poison in anything that does not convey at a glance that the contents thereof are poisonous, for several reasons, viz.: the label may become stained or blurred, or perchance come off, or a poison be placed in a beer or soda water bottle, or the bottle may be mistaken in a hurry or during the night, and the poison taken or administered for some innocent remedy, which we are well aware has been done some thousands of times. For this reason I have suggested the use of triangular phials because they are uncommon, and the green color will in, say, twenty-five years, become the color associated with poison. "Poison" is to be blown in the bottle because labels come off. A penalty is attached to using the bottle for any other purpose, because it is my intention that the public be taught that these bottles are for poisons and for nothing else, and whenever one of the bottles is found it is supposed to contain poison. As to the labels, this is, of course, in accordance with the present law.

To neglect so easy and so economical a means of security against the possibility of an accident, and the protection of a public that is ignorant of the potency of poison is criminal. It is as obligatory upon us to provide this precaution as it is for a city government to force sellers of gunpowder to keep their stores beyond the city limits, and for the

national government to maintain lights along the coast for the guidance of mariners.

It would, of course, be detrimental to the physician to label a bottle "poison" without his consent, but as a public safeguard none but he who had no regard for other than his own interests would be likely to object to the bottle, box, or package bearing the words: To be used with caution and kept out of the reach of children.

A BILL TO AMEND THE LAW REGULATING THE PRACTICE OF PHARMACY.

Be it enacted by the General Assembly of Virginia that it shall be unlawful to retail the following:

Arsenic and its preparations; phosphorus and its preparations; bichloride of mercury; white precipitate; biniodide of mercury; cyanide of potassium; hydrocyanic acid; essential oil of bitter almonds. Also the alkaloids of aconite, belladonna, opium, colchicum, conium, nux vomica, coca, digitalis, henbane; or their salts, and such other alkaloids and principles of a poisonous nature, as may be discovered from time to time; or any compound mass, pill, solid, or liquid, containing any of them in sufficient quantity to produce death; except upon the written order of a physician.

It shall be deemed unlawful to retail aconite, belladonna, colchicum, conium, nux vomica, hyoscyamus, savine, ergot, cotton root bark, cantharides, opium, or their pharmaceutical preparations (unless they contain less than two grains of drug to the fluid ounce) in quantity of more than a drachm or a fluid drachm of a preparation, either solid or liquid; or more than one quarter ounce of croton oil, chloroform, chloral hydrate, sulphate of zinc, carbolic acid, or any other poison that may be discovered from time to time, except upon the written order of an officer of the law, a physician, veterinary surgeon, dentist, or analytical chemist.

It shall be unlawful to retail any of the foregoing poisons without first recording in a book, kept for the purpose, the name and address of the purchaser, name and quantity of poison sold, date of sale, the purpose for which it is to be used, and the name of the dispenser. The record thus kept is to be always open for inspection by the proper authorities.

It shall, further, be unlawful to retail or dispense any of the foregoing poisons in any other than a triangular green phial or bottle, with the word "poison" blown in the glass (whether it be a solid, liquid, pills, tablets, or parvules), and the same to be plainly labelled with the name of the seller, his place of business, and the word poison printed in red letters on a white label, or to use these bottles for any other purpose excepting poisons dispensed upon a physician's prescription, in which case the phial or bottle shall bear a label printed in red letters on a white ground as follows: To be used with caution and kept out of the reach of children, and, if a box, envelope, or package, it shall be sealed with a slip bearing the above words.

Any violation of these statutes shall be punishable by a fine of \$25.00 for each separate offense from and after the passage of this act.

THE DIAGNOSIS AND TREATMENT OF
TYPHOID FEVER.

By WILLIS JONES, M. D.,

ATLANTA, GA.,

LATE HOUSE PHYSICIAN, BELLEVUE HOSPITAL, NEW YORK.

I know of no disease in the field of internal medicine which has been so extensively discussed as has typhoid fever, and yet the subject is still inviting and full of scientific interest. Scarcely a medical journal leaves the press that does not treat of the subject in some manner. Very few diseases coming under the jurisdiction of the student of internal medicine call for an earlier diagnosis than does typhoid fever. Upon the earliness with which the diagnosis is made depends much in reference to the prognosis of individual cases and the success with which the medical attendant will handle his charge, for it is a fact well recognized that the so called latent, or ambulatory, cases add very materially to the death percentage of this particular disease.

What is there in the early days of the disease which will aid us in making the diagnosis? A patient may come to you complaining of all the classical symptoms, viz., headache, which has existed for two or three days; pain in the back, a feeling of general languor, loss of appetite, constipation or diarrhoea, bleeding from the nose, and occasionally a slight bronchial cough. These subjective symptoms, reinforced by a close physical examination in which we find the tongue coated, a few rose spots upon the abdomen, the spleen enlarged, and a slight elevation of body temperature, with negative findings in the remaining portion of his or her anatomy, constitute to my mind an ideal early clinical picture of typhoid fever. However, only a very small percentage of the patients will present such a characteristic picture, but will come to you complaining of only one or more of the subjective symptoms above mentioned, and your objective examination may or may not prove completely negative, and yet the patient is suffering from the same kind of infection as the one which presented all the classical subjective and objective manifestations.

It is here that other aids in diagnosis must be employed if we expect to do all possible for our patient. We have at our command several laboratory methods, which are of much value in these doubtful cases:

1. A bacteriological examination of the blood can be made. When this has been done and the typhoid bacillus found, the diagnosis is established beyond doubt. This method of diagnosis is not available to everyone, because of the equipment that is necessary to carry out the examination.

This method, therefore, cannot be used as a routine practice except in hospitals.

2. We can make a careful morphological study of the blood, and in many doubtful cases we gain much valuable information. The chief thing in this study is the total estimation of leucocytes and a differential count of all the leucocytes present. It is well established that the total leucocyte count in an uncomplicated case of typhoid fever is practically normal or slightly below the normal. The diminution is usually in proportion to the severity of the infection. Thus in some very severe cases, counts as low as one thousand per c.m. are recorded. We can thus readily see that any sudden increase in the number of leucocytes should lead us to suspect some complication, since typhoid fever is one of the febrile conditions in which we expect a hypoleucocytosis rather than a hyperleucocytosis. In the early days of the disease is most usually to be found an increase in the number of lymphocytes and a corresponding decrease in the multinuclear neutrophile leucocytes. This condition is usually more marked in the third and fourth week of the disease. In cases where we have complications the multinuclear leucocytes are usually increased if the complication is septic in character.

3. Ehrlich's diazo reaction is quite significant, provided we can exclude pneumonia, scarlet fever, malaria, measles, and tuberculosis. Simon, in his treatise on clinical diagnosis, states that if in doubtful cases the reaction is found between the fifth and thirteenth day of the disease, and not later than the twenty-second day, it is presumptive evidence that the given disease is typhoid. If the reaction is not found in the second or third week of a supposed case of typhoid, it is probable either that the case is very mild or the diagnosis is wrong. This reaction is also very constant in acute miliary tuberculosis, but does not generally appear until after the beginning of the third week.

4. Probably of most importance to the general practitioner is the agglutination test, or Widal's reaction. This reaction is present in from 90 to 95 per cent. of all the cases of typhoid fever in some stage of the disease. By the aid given to us by the health department in the larger cities this method becomes one quite practicable. Ewing, in his recent book on the pathology of the blood, states that the reaction in cases where the dilution is 1 to 60 may be looked upon as *absolutely* certain, where the time limit is from fifteen to thirty minutes, and when the dilution is 1 to 30, must be regarded as *almost* certain evidence that the given case is one of typhoid fever. In other words, the significance of this reaction is directly

proportional to the dilution used and the time required for the agglutination to take place.

In summing up, I shall use Dr. Ewing's exact words in reference to Widal's test in the diagnosis of typhoid fever, which are as follows:

"The combination of an indistinct serum reaction, diminution of fibrin, absence of leucocytosis, and the presence of a relative or absolute lymphocytosis can very rarely be demonstrated in the early stages of any obscure febrile disease other than typhoid fever."

This method of diagnosis has recently been much simplified by the use of the dead or embalmed typhoid bacilli in bringing out the reaction, and in the hands of those who have used it, it has proved quite satisfactory.

The diseases that sometimes give us trouble to distinguish from typhoid fever shall be mentioned only. Those which often simulate typhoid are: Acute malarial tuberculosis, cerebrospinal meningitis, central pneumonia, malarial fever, or some deep seated suppuration. I think that probably the most difficult distinction is that between typhoid and acute miliary tuberculosis. I have seen cases where the very best diagnosticians could not say which condition was present until after they had studied the case daily for several weeks, and then only after many laboratory procedures had been resorted to in trying to exclude the one or the other condition, and in many cases only the autopsy revealed the condition which produced death.

As for treatment, I consider the prophylactic as of a much importance as any. The importance of this procedure I consider cannot be more vividly impressed upon medical attendants, nurse, and family than by calling attention to the great epidemic of typhoid which recently occurred at Ithaca, N. Y., as the result of the city water supply becoming contaminated by the excreta from some Italian laborers who were suffering from the disease. It is quite universally accepted that the germ of typhoid is given off from the body of the patient suffering from the disease in the urine, the feces, and, in a very few cases, the sputum. One authority has estimated that as many as 500,000,000 typhoid germs may be found in 1 c.c. of urine from a typhoid patient. In every instance where there is a case of typhoid in a private family, the actual life saving necessity of thoroughly disinfecting the urine, feces, and sputum before they are dumped into a cesspool, if in country or small village, and into sinks, if in larger villages or cities, should be impressed upon those who are acting in the capacity of nurse. Each time after the patient's bowels move, or urine is voided, the but-

tocks should be wiped off with 1 to 1,000 bichloride solution and, in women, the external genitals should be treated likewise, and here the attendant should be warned as to the necessity of thoroughly cleaning his or her hands after each such procedure. Bedding, or articles of clothing, used by the patient should be handled with care and immediately after being taken from the sick room should be placed in 1 to 20 carbolic acid solution, 1 to 1,000 bichloride solution, or, best of all, into boiling water. All drinking glasses and dishes used by the patient should be placed in boiling water before used by any one else. For the purpose of disinfecting the urine and feces, the best agents are 1 to 20 carbolic acid solution, 1 to 1,000 bichloride of mercury solution, which has been rendered acid by the addition of tartaric or hydrochloric acid in sufficient quantities; otherwise, the mercury would prove inert in the presence of albumin. The time required for these agents to act is from thirty minutes to one hour. The longer the more thorough the action. In each instance the quantity of disinfecting fluid should be equal in volume to the urine or feces to be disinfected, and all fecal masses should be thoroughly broken up to allow each particle to come in contact with the disinfecting agent. As for the internal treatment of individual cases, I think almost every one, other than members of the family, will agree with me that in certain selected cases of typhoid fever, we need no treatment whatsoever other than good nursing and proper and systematic feeding.

There is another type of the disease in which the patient seems to do best by controlling temperature, by proper bathing, feeding, nursing, and the administration of small doses of hydrochloric acid after each feeding, and no other medication save an occasional hypnotic. However, the greater number of cases of typhoid at some time of the disease will require special medication to control one or more disturbing symptoms. Usually one of the most persistent and annoying things to combat is hyperpyrexia, and for this condition I think that the bath treatment should stand at the top of the list. Unless the temperature mounts up higher than 102.5° F., bathing as a routine practice had better not be done; but when the temperature is above 102.5°, the cold bath is indicated and gives results that no other agent can. It is entirely free from the depressing after effects that are so often seen when the coal tar products are used. There are several ways in which the bath can be administered, depending upon the susceptibility of the patient to reaction and the environment in which the patient happens to be

placed. The most satisfactory way of giving the bath is by the use of a tub if this can be done. The next best is the bed bath, and in other cases the sponge bath has to be resorted to. Another method which is most heroic is the sprinkle bath, and personally I do not care to employ it. The temperature of the water in which these baths are given has to be varied; some very nervous patients will not stand the bath temperature below 90° or 85° F., while others do not object when the temperature is reduced to as low as 65°, but such a low temperature is not necessary to accomplish good results, and I consider that just as much benefit is derived from baths with the temperature ranging from 75° to 70° as when the temperature is reduced much lower. The number of baths in twenty-four hours will depend upon the condition of the patient and the reaction following each. Not more than six to eight baths should ever be given in twenty-four hours.

Peabody, in his clinical lectures on hydrotherapy, gives the cold bath treatment for hyperpyrexia credit for the following good features:

"The bath removes heat from the body, stimulates the system at large, stimulates the depressed nervous centre, relieves headache, delirium, and stupor, the heart's action is stimulated, the pulse made stronger and slower, general nutrition improved, and body oxidation diminished."

No such group of beneficial results has ever been attributed to any other agent used to reduce excessive bodily temperature.

While a great advocate of cold water to control temperatures and nervous symptoms in typhoid fever, I believe just as strongly in the internal administration of the same agent in quantities amply sufficient to meet the demands of what would be an ordinary thirst, and especially should this be done when the patient is in a semistuporous condition and does not ask for anything. In such cases, four to six ounces of water should be given every three to four hours. Water taken internally acts as a diuretic, diaphoretic, and laxative, and while it may in no way influence the increased bodily metabolism, it greatly aids in washing the lymph spaces of those products which are accumulated by the increased tissue destruction going on in the organism as the result of continued high fever.

We are oftentimes greatly worried in the attempt to get our patient to take and retain the requisite amount of nourishment. In some cases the stomach is so very irritable that vomiting results whenever anything is taken into the stomach, and it is frequently necessary to cut out all food for ten to twenty-four hours in order to control this dis-

tressing symptom. In well regulated institutions, where the patients are regularly fed and only small quantities used at each feeding, such irritability of the stomach is rarely seen. In one of the largest hospitals in the country, the following diet is used: Four ounces of milk, rendered slightly acid by the addition of hydrochloric acid, is alternated every two hours with four ounces of one of the following foods taken in regular rotation: coffee and milk, albumen water, kumyss or matzoon, beef juice, barley water, and broth. Where such an alternation is made with the milk, the chief diet, the patients do not become so very disgusted with the sameness of food, and where such routine is practised very little nausea and vomiting are seen.

Constipation in most cases of typhoid is present at some stage of the disease, and after the initial cathartic (calomel, one half grain every half hour, for six doses, followed in six to eight hours by one half ounce of Rochelle salts), has been given, I prefer that bowels be moved afterwards once in each twenty-four hours by a simple enema. The so called eliminative or purgative treatment I shall mention only to condemn, since it does not appear rational when we consider the pathological lesions present in the intestinal tract.

Stimulation is a thing greatly overdone in a great many cases of typhoid and, as a result, many patients in the latter part of the third and fourth weeks, when there is real need for stimulation, do not respond because of the abuse of stimulation earlier in the disease when there was no demand. The best agents for this purpose are whiskey and strychnine given singly or combined; however, some patients do just as well when caffeine and camphor are employed. Digitalis is a drug that I personally do not care to use for this purpose, for others are just as efficient and free from irritating effects upon the stomach.

Strychnine had better be cut out of our list when there is present a supersensitiveness of cord reflexes, manifested by increased patella reflex. If given in this class of cases, I think more injury than good is the result.

We meet occasionally a patient much exhausted from continued wakefulness, and these patients seem always to do best if given morphine in quantities sufficiently large to produce sleep, and the dose repeated at a later date if no rest can be had otherwise. Much comfort can be given a patient if his or her mouth is kept thoroughly clean with boric acid solution. I have seen bad cases of parotiditis which I think were the result of not looking after the patient's mouth, and I am

quite sure that in many cases an irritable stomach is much aggravated by the patients, continually swallowing the secretions from a foul mouth, and having all food and drinks which they take contaminated by the same condition. Hæmorrhage should, as soon as recognized, lead us to administer morphine in doses large enough to quiet peristaltic movements of the gut, ice should be applied externally over the abdomen by means of an ice cap or ice coils, all foods stopped for eight to fifteen hours, and the patient kept perfectly quiet.

Perforation, one of the saddest and most serious complications of typhoid, and usually recognized as a hopeless condition, should be met as soon as possible after diagnosis by surgical interference. The results in cases thus treated when the diagnosis was made early have been most gratifying, and since we have no other avenue of hope to offer our patient, when once convinced that his peritoneal cavity is contaminated, we cannot too strongly insist upon giving to the unfortunate subject the only remedy which can lead to perfect recovery, the alternative being a speedy death.

A Medical Class Reunion.—The class of 1895, medical department of New York University, held a class reunion and banquet at the Hotel St. Regis, Tuesday evening, May 9th, to celebrate the tenth anniversary of graduation. Although reunions of medical college classes are unusual, this was a success, and brought together fifty-six of the ninety-seven surviving members of the class. Dr. Eben Foskett, of 314 West Eighteenth Street, presided, and remarks were made by Professor John F. Brady, of Dunwoodie Seminary, Yonkers, N. Y.; and Dr. Carl V. Reynolds, of Asheville, N. C.; Dr. H. L. Borland, of Camden, N. Y.; Dr. L. B. R. Smith, of Jeannette, Pa.; Dr. Edward Day, of Binghamton; Dr. F. C. Adams, of Bridgeport, Conn.; Dr. A. P. Bergman, of New Haven, Conn.; Dr. M. Vance, of Massachusetts; Dr. E. T. Sharpe, of Derby, Conn.; Dr. Charles J. Pflug, of Brooklyn; Dr. J. Feldstein, late of Calcutta, India; Dr. William J. Narey, Dr. J. F. Connors, and Dr. R. Opdyke, of New York; Dr. T. J. Kilmartin, of Waterbury, Conn.; and others. Of the one hundred and one men graduating in this class, ninety-seven are living, and ninety-five of them are engaged in medical work at the present time. It was voted to have another reunion five years hence.

The Dinner to Dr. Emmet.—We again remind our readers that the friends and admirers of Dr. Thomas Addis Emmet propose to give him a dinner on May 29th in celebration of his seventy-seventh birthday. This dinner will be given at Delmonico's and prominent physicians from New York and other cities will be present to do honor to one who has reflected such lustre upon American gynecology.

Correspondence.

LETTER FROM TORONTO.

Resignation of the Superintendent of the Toronto General Hospital.—The Ontario Board of Health.
—The Ontario Hospitals Association.—Dr. Grenfell's Benevolent Work.

TORONTO, May 1, 1905.

Dr. Charles O'Reilly, for twenty-nine years medical superintendent of the Toronto General Hospital, has handed in his resignation, which will be accepted and take effect at the end of June. Dr. O'Reilly was appointed to this office in 1876, coming from the Hamilton, Ontario, Hospital. During the course of his long administration, which has been an exceptionally brilliant and effective one, he has seen the staff increase from twelve to sixty, and has been instrumental in building up this hospital until to-day it is the largest institution of its kind in the Dominion of Canada, capable of accommodating over 400 patients, and having all the time within its walls a floating population of 500 souls. During the long tenure of his office over 100,000 patients have been treated in the institution, and there have occurred over 4,000 births in the maternity department. It has established an eye and ear department, as well as a nose and throat clinic and a skin clinic, in addition to the every day surgical and medical clinics. Several years ago Dr. O'Reilly was instrumental in having established an emergency branch in the centre of the city, a branch which annually attends to over 2,500 emergency cases. He has been on different occasions examiner for Toronto University, Trinity University, and the Ontario College of Physicians and Surgeons, and is vice-president of the Association of Hospital Presidents for the United States and Canada, as well as vice-president of the Ontario Hospitals Association. Popular with his staff and with the physicians of Toronto and Ontario, most of whom have passed through his hands, Dr. O'Reilly and his genial presence will be greatly missed; and the board of directors will find it a difficult matter to secure his equal as a hospital administrator. For the next two years Dr. O'Reilly will travel abroad with his wife and only son, Dr. Breffney O'Reilly.

The regular quarterly meeting of the Ontario Board of Health was held in Toronto on the 27th and 28th of April, when the secretary, Dr. Charles A. Hodgetts, presented the quarterly report of the work done by the board. For the first three months of 1905 there were 500 deaths from tuberculosis, and the continuation of this lamentable and appalling death rate from this disease will

stimulate the board to renewed vigor in endeavoring to stay its ravages. As a measure of relief Dr. Hodgetts suggests that, until such time as there should have been established throughout the Province sanatoria sufficient to grapple with the advances of the plague, the dispensaries should give provisional treatment. Another important subject mentioned and subsequently discussed was that of the disinfection of sleeping cars. Dr. Hodgetts thinks that there ought to be disinfecting stations elsewhere than at divisional points, and advocates having forms for certifying to the last disinfection and to the daily disinfection of all Pullman and sleeping car blankets. The subject of infant mortality was also discussed, and it was suggested that parents should be educated as to how their children should be fed, and that the board should issue circulars giving instructions on infant diet. The advisability of establishing a separate Department of Public Health in the Ontario Government will be discussed at the next regular meeting, and in the mean time the members of the board will have an opportunity to ponder the following notice of a motion regarding the same: "Owing to the constantly increasing attention given to sanitation, and the influence of proper sanitary methods on the public health, it is advisable that the Ontario government do establish a separate Department of Public Health which will be presided over by a responsible minister of the Crown."

The Ontario Hospitals Association held its annual meeting in Toronto on the 12th of April. A deputation from the members waited on the Premier, the Honorable Mr. Whitney, seeking an increase in the annual grant to the Provincial hospitals, from 50 to 75 cents a day, as the former amount is found insufficient. The total annual government grant to the Ontario hospitals now amounts to \$110,000, and as the number of patients is annually increasing, the amount per capita gradually decreases. During 1904 the hospitals throughout Ontario treated 39,223 patients, against 35,912 in 1903. The total revenue for the maintenance of these amounted to \$844,881, which amount included the government grant of \$110,000. This gives about 17 cents per diem for each patient entitled to receive government aid, while the actual cost of each of these patients was 89 cents a day. The total expenditure for 1904 amounted to \$841,829. For 1903 it was \$784,643. Mr. Edward Gurney, of Toronto, was elected president, Dr. Charles O'Reilly vice-president, and Dr. John Ferguson, of Toronto, secretary and treasurer.

Dr. Wilfrid Grenfell, the young Englishman who devotes his medical life to the fisherfolk of

Labrador and the northwestern shores of Newfoundland, is at present in Toronto, and has been delivering a series of lectures upon his work in that remote region of civilization. Since embarking upon this work, thirteen years ago, he has established three hospitals and has had presented to him a hospital ship by Lord Strathcona. That the hospitals are primitive and not of the modern variety can be gathered from the fact that one patient had an ear frozen while lying in bed last winter. Dr. Grenfell is greatly to be commended for his charitable work. He ministers to the sufferings of some 2,000 people each year, sometimes travels over a hundred miles to reach a patient, and has them brought equally long distances to him. He has secured the services of two specialists for the coming summer.

Therapeutical Notes.

Uresin, a Urotropin Compound.—Spasski states in *Roussky Vrach*, for April 2, 1905, that he prepared, in 1898, a dilithium-citric-acid-compound of urotropin, which he called uresin, and which is said to be a solvent for uric acid. (Urosin, a preparation better known and having a similar name, is the quinate of lithium.) Spasski experimented with citric acid, with urotropin, with urotropin citrate, with lithium citrate, and with uresin, and compared the amount of uric acid eliminated, the nitrogenous exchange and the amount of oxalic acid eliminated when these drugs were given. He found that urotropin did not act on nitrogenous metabolism. It was merely a solvent of uric acid. On the other hand, the administration of the other four preparations was followed by a diminution of nitrogenous metabolism and by an increased amount of oxalic acid eliminated. The increase of oxalic acid takes place at the expense of the uric acid. He considers uresin to be the most satisfactory of these remedies, because it is the most stable and the least hygroscopic.

Olans are compounds of petrolatum which have the property of forming permanent emulsions with water in the proportion of one part to five up to one part in two. They are absorbed by the skin. do not soil the clothing, and are said to have no caustic action. Various compounds are prepared, such as iodolan, naphtholan, etc. Iodolan contains free iodine and not iodine combined with fatty acids, as in the case of similar preparations. Naphtholan is prepared with a residue of Russian brown naphtha, and looks like yellow petrolatum, but is easily emulsified, and is specially recommended as a vehicle for ointments with balsam of Peru. The compound is easily applied and readily washed off. The makers do not divulge the method of preparation nor the composition of the olans.

The Kansas City, Mo., Hospital has decided to add an inebriates' ward to that institution to which chronic drug users may be committed by the city magistrates.

NEW YORK, SATURDAY, MAY 20, 1905.

REGULATION OF THE SALE OF POISONS.

It will be seen from the article by Dr. Barksdale which is published in this number of the *Journal* that an agitation for a revision of the State pharmacy law of Virginia in its application to the sale of poisons has been started in that State. Dr. Barksdale proposes a simple method of dealing with a serious situation which has grown out of the indiscriminate sale of common poisons by pharmacists, and the details of this are given in his article.

The sale of poisonous drugs at retail is regulated in nearly every State in the Union according to provisions contained in the several State pharmacy laws. The State of New York is one of the exceptions, for, by a section of the Penal Code, poisons must not be sold at retail except under certain restrictions, such as registering the sale and affixing a cautionary label to the container. This year, however, an effort has been made to strike out certain of the provisions of the Code which conflicted with the poison sections of the State pharmacy law. The necessity of an occasional revision of the pharmacy laws, especially of their poison sections, will be apparent when the advances of chemistry and pharmacy in recent years are taken into consideration.

We are heartily in favor of any movement having for its object the surrounding of the sales of

poison at retail with increased restrictions; we therefore take the liberty of commending Dr. Barksdale's plan to the American Pharmaceutical Association, which through special committees has given considerable study to the subject, going so far as to draft a model poison law and to recommend it for adoption by the several State pharmaceutical associations throughout the country. Nearly every piece of legislation pertaining to the practice of pharmacy in this country has been initiated by pharmacists, and we think it would be well to allow pharmacists, through their representative national associations, to continue to direct such matters. Dr. Barksdale's article is one of timely interest and is likely to prove suggestive and valuable for those who are concerned in the matter of throwing safeguards around the sale of poisons.

But the danger is not confined to sales of recognized drugs. In our issue for December 10, 1904, under the heading of *The Indiscriminate Use of Dangerous Drugs*, we spoke of the dangers resulting from the unrestricted trade in preparations not popularly looked upon as poisonous, but really of a dangerous character. Such are many of the quack preparations. Apropos of that article a distinguished member of the Committee of Revision of the United States Pharmacopœia wrote to us concerning an exceedingly dangerous arsenical preparation advertised and sold to the public indiscriminately as a remedy for asthma.

METADIPHTHERITIC SCARLATINOID.

This name is applied by Marfan (*Presse médicale*, April 29th) to a febrile affection accompanied by a rash indistinguishable from that of scarlet fever, and not with certainty to be distinguished otherwise from that disease, occurring after diphtheria that has been treated with antitoxine. The affection itself has been observed ever since the antitoxine treatment came into vogue, but it has been variously explained, some regarding it as purely the result of the serum used, while others have imputed it to a secondary streptococcus infection.

M. Marfan is inclined to look upon it as a true scarlet fever, modified perhaps by the diphtheria or by the antidiphtheritic serum. It is to be dis-

tinguished, he says, alike from the relapsing desquamative scarlatiniform erythema of the dermatologists and from the ordinary infectious erythemata, which, for that matter, are not exclusively scarlatiniform, but display a more or less decided polymorphism. But, he continues, if the scarlatiniform erythema is due to a secondary infection, if it really represents an abnormal scarlet fever, if, in short, the serum has nothing to do with its development, how are we to explain the fact that it seems to have become more frequent since the adoption of the new treatment of diphtheria? Possibly, he answers, this greater frequency is only apparent. At the present time the serum treatment allows diphtheria in its grave forms to display its full evolution, whereas formerly death cut it short in the early days of its course. Hence we now frequently observe accidents that were rarely seen before 1894. This consideration, which he thinks very important, inclines M. Marfan to the view that diphtheria as modified by the serum treatment is a new disease. If metadiphtheritic scarlatinoid is really a modified form of true scarlet fever, it is almost invariably very mild in its course, but probably it is in no great degree protective against a subsequent attack of scarlet fever.

A REMARKABLE CASE OF FOREIGN BODY IN THE VAGINA.

For purposes of their own, women occasionally introduce foreign bodies into the vagina, but, apart from pessaries, we presume it is rare for such bodies to be inserted by others. Certainly a case recorded by Dr. Placide Dubois in the *Gazette médicale de Nantes* for April 29th exemplifies an extremely rare if not unique occurrence. It came under Dr. Dubois's observation so long ago as in 1893, when he was a medical officer of the French colonial service in Cochin China.

An Annamite woman named Thi-Ly, thirty-one years old, of robust and healthy appearance, though evidently in great pain, presented herself at the native hospital of Phu-My for the purpose of having something made of wood and iron removed from her vagina. She said that it had been introduced on the preceding day by an Annamite doctor, adding the astonishing statements that he

had inserted it as an act of vengeance and that he had done so while she was asleep. In his examination M. Dubois found that the labia minora were very small, and he remarks that in many of the Annamite women the nymphæ are exceedingly small, scarcely amounting to a fold.

The foreign body proved to be an infernal contrivance, and its removal was a matter of considerable difficulty. It was a piece of hard, black wood, whittled into the rough semblance of a penis, the glans being made of some material having the appearance of wax, but much harder. Ranged round the wooden shaft, and held in place each by one end in the sulcus behind the glans by what appeared to be an elastic band, there were nine pieces of stout iron wire sharpened at their free ends. These pieces of wire projected backward and in a radiating direction like the ribs of an umbrella three quarters open, and several of them had penetrated the vaginal wall. The whole thing was about two inches and a half long, and the iron wires varied from half an inch to an inch in length. It was found necessary to incise the vaginal wall slightly to liberate these barbs. Although rest was enjoined after the removal of this savage device, the woman left the hospital on the following day, feeling absolutely no inconvenience, and two days later she was found to have only two minute sinuses as the result of her injuries.

Dr. Dubois justly remarks upon the devilish ingenuity displayed in the fabrication of this instrument of torture, and intimates that it may have been designed for the same purpose as the old *ceintures de chasteté*. It is somewhat difficult to believe the woman's declaration that it was introduced while she was asleep.

SOME POTENT THERAPEUTIC INFLUENCES, PRESENT AND PROSPECTIVE.

It cannot have escaped the observation of any one who may have turned his attention to the subject that the treatment of disease, or perhaps it is more correct to say the method of treatment of many diseases, is undergoing a process of change which is more or less revolutionary. The era of polypharmacy, with its multitude of drugs, the use of many of which is often in the high-

est degree empirical and unsatisfactory, is passing away. Of course the time is far distant, and it may never come, when drugs will be discarded, but it is evident that the utility of many of them as means for the possible cure of disease is less highly regarded than was formerly the case, and in many instances they have given place to one or another of the agencies which form the subject of this article.

These agencies, which will constitute at least an important part of the therapeutic system of the future, rest upon as solid and substantial a basis of scientific fact as almost anything outside the realm of pure mathematics. Whether we are to regard the changes which are taking place in practical therapeutics as evolutionary or merely as phases in psychological activity, it is impossible to say; and the one hypothesis does not necessarily exclude the other.

One of the most important therapeutic agencies is mental influence, it matters not by what name it is called. Physicians, of all men, are in a position to admit its potency for curative ends. It is by no means a recent discovery, for from time immemorial the influence of one mind over the mind and body of others has been recognized and admitted. Its scope is enlarging, for many people are awakening to the fact that they are susceptible to an extraordinary degree to the mental influence of those with whom they are in harmony. The more it enlarges the more useful it will become if properly regulated and systematized.

Hydrotherapy is a means of treatment for which the future is holding out great promises. Much has already been accomplished by it, especially during the past twenty-five years. Further study and elaboration will be sure to amplify its field of usefulness. One need only recall the valuable results which it has yielded in the treatment of typhoid and other fevers, diseases of the heart, liver, and kidneys, and a great number of the eruptive diseases to realize the importance which already belongs to it. Lavish Nature has supplied us with water in almost unlimited quantity, and it is often combined with powerful substances for relieving sickness and disease. It cannot be doubted that in the near future we shall

obtain much additional knowledge as to its practical applicability.

Massage and muscular motion as means for the treatment of disease have a much greater range of usefulness than is ordinarily supposed. When we realize what has been accomplished by this agency in the past, the health and beauty and vigor which it brought to the ancients, especially the Greeks, we do not wonder at the enthusiasm of those who advocate its systematic use. Muscular activity means quickened circulation, nervous energy, improved performance of function, enhanced metabolism, and general well being. The Swedish and other forms of movements, gymnastic exercise, and various forms of rubbing and manipulation are too valuable to be discarded or disregarded, or left in the hands of the half educated or the charlatan.

Treatment by means of serums and animal extracts is one of the most brilliant of the modern contributions to therapeutics. Though we have enjoyed the beneficent effects of vaccination for a century, it yet seems almost incredible that the blood of living animals can be utilized to furnish antidotes to poisons in the human circulation.

What great expectations may we not be justified in holding for the future when deadly diseases like smallpox and diphtheria have yielded to the power of this form of treatment? The opportunities which are being opened in this field are well nigh boundless in their scope and in their capacity for usefulness.

Finally, we are now at the threshold of the great developments which are to come with the more complete understanding and more perfect adaptation of the physical forces, heat, light, and electricity. We have long been familiar with the useful results of moist heat by means of the simple or medicated hot bath, the Turkish bath, etc., but the scientific employment of dry heat is of recent date. It is remarkable that dry air may be used at a temperature a hundred degrees or more beyond that which would be safe or useful with moist air. The relief of surgical shock and the care of many chronic disorders which may be accomplished by dry heat are evidences which we already possess as to its great value. Equally astonishing are the results which are being ac-

complished by means of light. The Röntgen rays, the Finsen rays, and the emanations from radium are opening fields for investigation in practical therapy of which we have as yet but little conception.

It is not improbable that we shall find equally beneficent results from the use of electricity. Though its therapeutic effects have thus far been limited and often disappointing, it is hardly possible that an agent which is so closely allied to nervous energy can be without great utility for the cure of disease. These new therapeutic agencies come to the relief of internal medicine, for in the form of the serums and extracts antidotes to poisons are introduced into the body, the selective affinity for which has been ascertained by patient experimentation and inductive reasoning. In the presence of pestilences and scourges, the cause having been determined and recognized, it becomes a simple matter to apply the appropriate antitoxine.

They come to the relief of surgery in the form of the physical imponderable forces, destroying tissue which is manifestly diseased and going beyond that which is pathological to sight or touch, beyond the limit which is usually reached by the surgeon's knife.

To physical forces or to animal extracts we must look, in all probability, for the cure of malignant disease, which has thus far baffled all other means of treatment. What a vista is opened for the future by these remarkable agencies! Disease is an accompaniment of civilized life to a far greater degree than in more primitive social conditions, but the expanding and developing human intellect is gradually clearing the way for the removal of much of it, and there is every reason to believe that this progress will continue. Who would dare to prophesy what the ideal social condition, in the dim future, will bring in the way of relief and cure?

ANDREW F. CURRIER.

THE COMPARATIVE VIRULENCE OF HUMAN AND BOVINE TUBERCLE BACILLI.

The comparative behavior of human and bovine tubercle bacilli was lately made the subject of a number of experiments upon various large animals by three of the medical officers of the Bureau of Animal Industry, the late Dr. E. A. de Schweini-

nitz, Dr. Marion Dorset, and Dr. E. C. Schroeder. A report of the experiments has recently been issued by the Department of Agriculture in the form of a brochure of 100 pages, very handsomely illustrated, largely in colors. The authors regard some of Koch's experimental requirements as unnecessary and unreasonable, and it is their opinion that the intertransmissibility of human and bovine tuberculous disease is supported by so much indirect evidence of an overwhelming character that we are justified in looking upon it as practically established.

STRAINING PROFESSIONAL COURTESY.

We learn that on May 15th an Italian physician of New York was arraigned on a charge of furnishing a death certificate in the case of a child he had never seen, who had died under the care of an unqualified quack. On the physician's counsel pleading in extenuation that such was the universal practice in the region around Sullivan Street, where the doctor lived, he escaped with a fine of seventy-five dollars instead of a sentence to nine months' imprisonment, which the judge had first thought fit to impose upon him. When we reflect on the chances to conceal crime developed by this amiable custom, it really seems as if the desire to help a needy comrade, qualified by the State or not, might lead to consequences in the highest degree detrimental to that *entente cordiale* that should always prevail between members of the medical profession and the police authorities.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 22nd.—Medical Society of the County of New York; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, May 23rd.—New York Medical Union (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, May 24th.—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society; New York Dermatological Society (private).

THURSDAY, May 25th.—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Mass., Society for Medical Improvement (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.; New York Celtic Medical Society.

FRIDAY, May 26th.—New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, May 27th.—New York Medical and Surgical Society (private); Harvard Medical Society, New York (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending May 13, 1905:

	May 13.		May 6.	
	Cases.	Deaths.	Cases.	Deaths.
Measles.....	712	14	621	13
Diphtheria and croup.....	312	36	334	39
Scarlet fever.....	235	13	256	14
Smallpox.....	6	1	5	..
Chickenpox.....	129	1	137	..
Tuberculosis.....	471	195	414	181
Typhoid fever.....	87	3	81	10
Cerebrospinal meningitis.....	136	88	178	111
	2,071	350	1,971	368

The Women's Health Protective Association of Brooklyn held its annual meeting on May 12th, when the board of directors for the coming year were elected. Dr. Wolff Freudenthal, of the Eastern Medical Society of New York, and John H. Chase, head worker of the Maxwell House, made addresses.

Personal.—Dr. Thomas H. Curtin, physician to Coroner O'Gorman of the Bronx, is an invalid as a result of blood poisoning of the little finger of his left hand, on which he has already performed two operations himself. The poison was received through a small cut, inflicted in an operation on May 7th. The following day the finger began to swell and become discolored, whereupon Dr. Curtin opened the finger, hoping thus to remove the infection. This was not successful, and on May 10th he again opened the finger.

Medical Society of the County of New York.—A stated meeting of this society will be held at the Academy of Medicine, on Monday, May 22nd, at 8.15 p. m., at which the paper of the evening will be The Treatment of Diarrhoea in Children, by Dr. Joseph E. Winters. The discussion will be opened by Dr. Arthur V. Meigs, of Philadelphia, and continued by Dr. William H. Wells, of Philadelphia; Dr. A. D. Blackader, of Montreal; Dr. E. M. Buckingham, of Boston; Dr. Charles W. Townsend, of Boston; Dr. John Lovett Morse, of Boston; Dr. R. C. Newton, of Montclair, N. J.; Dr. Leroy M. Yale, Dr. John Dorning, Dr. William P. Northrup, Dr. Floyd W. Crandall, and Dr. Walter Lester Carr.

Academy of Medicine.—The Section in Laryngology and Rhinology will meet on Wednesday, May 24th, at 8.15 p. m. Order: Presentation of Cases: (a) Case of Unilateral Clonic Spasm of the Superior Constrictor Muscle, by Dr. Ed. B. Coburn; (b) Case of Pachydermia Laryngis, by Dr. Thomas J. Harris; paper: Report of the Garcia Centenary, by Dr. Harmon Smith; Presentation of Specimens and New Instruments, Lewis A. Coffin, M. D., chairman; Lee Maidment Hurd, M. D., secretary, 15 East Forty-eighth Street.

The Section in Obstetrics and Gynecology will meet on Thursday, May 25th, at 8.15 p. m. Order: Presentation of Specimens: Ruptured Ectopic Gestation of Right Horn of Uterus, by Dr. John J. McGrath; paper: A Study of the Results of Abdominal Hysterectomy for Fibroids with or Without Drainage, by Dr. Joseph Brettauer; discussion by members of the section. Charles F. Adams, M. D., chairman; Arnold

Sturmdorf, M. D., secretary, 51 West Seventy-fourth Street.

The Section in Orthopædic Surgery. The next meeting of this section will be held in October. Homer Gibney, M. D., chairman; S. A. Twitch, M. D., secretary, 598 Broad Street, Newark, N. J.

Approval of the Work of Dr. Doty.—The Consulting Board of the Health Officer of the Port of New York, consisting of Dr. J. D. Bryant, Dr. E. G. Janeway, Dr. H. M. Biggs, Dr. G. L. Peabody, Dr. F. P. Kinnicutt, Dr. J. H. Girdner, Dr. J. W. McLane, Dr. R. H. Derby, Dr. William M. Polk, Dr. J. W. Brannan, and Dr. T. M. Prudden, visited the quarantine on Saturday, May 13th, making a careful inspection of the station, hospitals, and laboratory. The board passed a formal resolution of approval of the high standard of efficiency which is maintained by Dr. Doty in the administration of this important agency in the protection of the public health. The consulting board believe that the administration of Dr. Doty is especially noteworthy and admirable in the following features: In the practical recognition of the fact that it is in the infected man and his immediate surroundings that danger lies, and not in the ship or its cargo or its healthy passengers; in the systematic use of the clinical thermometer for the detection of early and obscure phases of infection; in the application of scientific sanitary measures adapted to each special form of infectious disease; in liberal and humane efforts to ameliorate the hardships of necessary quarantine detention; and, finally, in the unwearied efforts, through laboratory research and experiment, to add to the knowledge of useful, practical sanitation. The members of the board who for many years have been conversant with the conduct of the New York quarantine expressed their cordial appreciation of the effective way in which each advance in the science and practice of modern sanitation has been at once applied to the complex problems of this great port. So that year by year, through new measures which Dr. Doty has himself devised and tested, or has made available from other sources, the country is more effectively protected against the entrance of communicable and other infectious diseases, while at the same time there is a steady reduction of the annoyances to individuals and damage to commerce in which earlier quarantine systems were constantly involved.

PHILADELPHIA.

Entertainment for Charity.—A vaudeville entertainment was given on Saturday evening, May 13th, at Kenderton Hall, Tioga, for the benefit of the Samaritan Hospital.

The Philadelphia Polyclinic.—During April the following cases were treated in the Polyclinic Hospital: Patients admitted to house, 117; patients discharged, 116; new patients treated in dispensary, 1,768; total visits to dispensary, 8,185; accident ward, 637. From May 1st to May 20th, inclusive, a special course in medicine was given with clinical lectures and laboratory demonstrations, which was well attended. From May 22nd

to June 10th a similar course in general surgery will be given.

Municipal Hospital Census.—The following is the census of the Municipal Hospital for April:

	Remaining April 1.	Received.	Discharged.	Died.	Remaining.
Diphtheria	37	91	65	12	71
Scarlet fever	95	40	47	2	86
Smallpox	2	0	1	0	1
Other diseases	3	7	2	4	4

Scientific Society Meetings for the Week Ending May 27, 1905.—Monday, May 22nd, Mineralogical and Geological Section, Academy of Natural Sciences. Tuesday, May 23rd, Northwest Medical Society; Philadelphia Neurological Society. Wednesday, May 24th, Philadelphia County Medical Society. Thursday, May 25th, Pathological Society; Entomological Section, Academy of Natural Sciences. Friday, May 26th, South Branch, Philadelphia County Medical Society; Northern Medical Association.

Physician Restrained from Practising.—On May 8th Judge Johnson in Media continued an injunction restraining Dr. David M. McMasters from practising medicine in the borough of Ridley Park. Dr. Howard Furness Taylor, the plaintiff, asserted that he had bought Dr. McMasters's practice in April, 1904, for \$300.00, with the understanding that the defendant should leave Ridley Park and not return. The plaintiff stated that the defendant after having lived in Pittsburgh for a year returned to Ridley Park in April of this year and opened an office, hence a breach of verbal contract.

The Health of the City.—During the week ending May 6, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Malarial fever	1	1
Typhoid fever	256	20
Scarlet fever	32	1
Chickpox	61	0
Diphtheria	54	11
Cerebrospinal meningitis	4	4
Measles	72	0
Whooping cough	14	0
Tuberculosis of the lungs	26	49
Pneumonia	57	62
Erysipelas	8	0
Puerperal fever	1	4

The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 11; tetanus, 1; dysentery, 1; diarrhoea and enteritis, under two years, 21. The total deaths were 481, in an estimated population of 1,438,318, corresponding to an annual death rate of 17.39 per 1,000 population. The total infant mortality was 112; under one year, 90; between one and two years, 22. There were 37 still births; male, 26; females, 11. There was one quite warm day, May 4th, in which the maximum temperature was 81° and the humidity was 92°. No other unusual phenomena were recorded by the weather bureau.

Bureau of Health Statistics.—During April the division of medical inspection made 2,894 examinations, exclusive of schools; 591 fumigations were ordered; 68 cases were submitted to special diagnosis; 4,915 visits were made to schools and 715 children were excluded. One hundred and nine cultures were taken, 115 injections of anti-

toxine were given and 519 individuals were vaccinated. In the division of milk inspection 4,643 inspections were made of 117,030 quarts of milk, of which 1,315 quarts were condemned. One hundred and thirteen samples were tested chemically and 670 microscopically. In the division of disinfection one fumigation was made for smallpox, 165 for scarlet fever, 221 for diphtheria, 318 for typhoid fever, 66 for tuberculosis, 89 for miscellaneous complaints, and 44 schools were treated. In the bacteriological laboratory 1,789 cultures were examined for diphtheria, 527 specimens of blood for the serum diagnosis of typhoid fever, 684 specimens of milk, and 146 of sputum were examined. One thousand three hundred and seventy-two bottles of antitoxine were supplied. In the chemical laboratory 165 analyses were made.

GENERAL.

The Cattaraugus County, N. Y., Medical Society has elected these officers: President, Dr. Clarence King, of Machias; vice-president, Dr. C. M. Coss, of Cattaraugus; secretary and treasurer, Dr. Carl Tompkins, of Randolph.

The Southwestern Kentucky Medical Association has elected officers as follows: President, Dr. S. Z. Hilland, of Grahamville; first vice-president, Dr. W. L. Mosby, of Bardwell; second vice-president, Dr. A. E. Prather, of Hickman; secretary, Dr. V. A. Stille, of Benton; treasurer, Dr. C. H. Brothers, of Paducah. The next meeting will be at Arlington in October.

Samaritan Hospital, Chicago.—The Samaritan Hospital is to take possession of the Hotel Normandie property at 339 to 341 Michigan Avenue, 50 by 171, and thirty feet adjoining on the north. Dr. L. Blake Baldwin has purchased from the Bordeaux Company the hotel building and lease hold interest and from Edward D. Thayer, Jr., the property on the north.

The Connecticut State Board of Health reports the following cases of infectious diseases for the month of April: Smallpox, 1; measles, 314; scarlet fever, 178; cerebrospinal fever, 53; diphtheria, 104; whooping cough, 18; typhoid fever, 30; consumption, 34. The deaths reported from infectious diseases are 163, being 12.1 per cent. of the total mortality, viz., 1,347.

Physicians Revert to Primitive Profession.—Dr. L. P. Jones, Dr. William L. Griswold, Dr. Virgil C. Piatti, Dr. Charles J. Klien, Dr. Charles H. Brooks, and Dr. Charles H. Clark, physicians, of Greenwich, Conn., dug the first earth for the excavation for the new general hospital building on the grounds of the Greenwich Emergency and Isolation plant on May 10th. The emergency and isolation plant was erected by a gift of Robert M. Bruce about three years ago.

Ophthalmic Hospital in Paris, France.—It is reported that the first ophthalmic hospital in Paris was opened without ceremony during the week ending May 6th. The institute has been founded by Baron Adolph de Rothschild, and has been fitted with every modern appliance. Two hundred patients were admitted the first day.

The building is a handsome stone and brick edifice constructed partly with old stones brought from Normandy and is designed generally to imitate the old Norman chateau. It will rank as one of the architectural beauties of the city.

The Wisconsin College of Physicians and Surgeons graduated the following on May 9th:

Anton Daniel Beier, William Wallace Brown, Francis Donahue, William Fox, Jacob Gomer, Alexander George Hough, Oscar Knutson, Bernard Krueger, George Alden Lewis, James Edward O'Connell, Arthur Reitman, Daniel Bernard Riley, William Louis Rohrer, Louis George Rupp, Charles Edgar Secor, Eugene Ford Smith, Charles Robert Stanhope, Charles Everette Stevens, Henry Charles Werner.

Larger Medical Corps for the Michigan National Guard.—The Minnesota State military board has promulgated orders increasing the hospital corps of the Michigan National Guard from 40 to 70 men and officers. Directions for instruction and inspection are given, which indicates that the importance of this branch of the service will be emphasized.

Medical Society of the County of Orange, N. Y.—At the ninety-sixth annual meeting of this society, held at Middletown on May 9th, the following officers were elected: President, Dr. E. Ross Elliott, of Montgomery; vice-president, Dr. A. C. Santee, of Scotchtown; secretary, Dr. M. A. Stivers, of Middletown; treasurer, Dr. W. I. Purdy, of Middletown.

Louisville National Medical College.—The eighteenth annual commencement of the Louisville National Medical College for colored students was held on May 5th. A large audience was present. Degrees were conferred upon W. H. Witherspoon, of Alabama, salutatorian; J. T. Bonner, John H. Frye, W. E. Cary, valedictorian; R. L. Silver, of Kentucky; and Esther A. Brown, of Indiana.

Franklin District, Mass., Medical Society.—The following officers were elected on May 9th: President, Dr. C. C. Messier, of Turners Falls; vice-president, Dr. V. P. Craft, of Greenfield; secretary and treasurer, Dr. C. F. Canedy, of Greenfield; censors, Dr. Norman P. Wood, of Northfield; Dr. J. W. Cramm, of Colrain; Dr. George R. Fessenden, of Ashfield; Dr. Enoch G. Best, of Greenfield; and Dr. C. G. Trow, of Sunderland; committee on trials, Dr. J. D. Seymour, of Whately.

The McGill-Bishops Consolidation.—The terms proposed by McGill University regarding the consolidation of its medical faculty with that of Bishops College seem to have been approved by the latter. It is understood, in regard to the draft agreement that the terms will provide for the students of Bishops entering McGill with an ad eundem standing. The names of the graduates of the two universities will appear in the same volume, but in separate lists, as long as there is no faculty of medicine attached to Bishops College. It is also understood that for the present no members of the medical faculty of Bishops will assume positions on the staff of the McGill medical faculty, although in the course of time

the former may be assimilated with the latter. It is also likely that the medals and prizes of the Bishops medical faculty will be transferred to McGill, subject to the consent of the university and the donors. If the agreement is finally ratified it will go into force at once.

Albany Hospital Training School.—The Albany Hospital Training School for Nurses held its commencement exercises on Wednesday evening, May 17th, in the study hall of the female academy. The members of the class are:

Miss Percy Loveday, of Albany; Miss Susan James Sullender, of Eagle Rock, Va.; Miss Effie Anne Nettleton, of Little Falls; Miss Florence Cornelia Heidle, of Ohio; Miss Marietta Frost Fitchett, of Poughkeepsie; Miss Edna Grace Bridgeford, of Albany; Miss Margaret Isabel Black, of Fergus, Canada; Miss Irene Rosemary Barrett, of Oneonta; Miss Irene Sarah Williams, of Fort Plain; Miss Grace Maud Wells, of Fort Plain; Miss Harriet Stark, of Albany; Miss Mabel Stephens Diack, of Rensselaer; Miss Elizabeth Ulrich, of Albany; Miss Anne Hervey Strong, B. A., of Albany; Miss Emily Anne Fraser, of Prince Edward's Island, Canada; Miss Margaret Gertrude McClellan, of Gananoque, Canada; Miss Sarah Ingalls, of Fonda; Miss Lulu Florence Schrader, of New Haven, Conn.; Miss Mary Walker, of Schenectady; Miss Edith Alma Loomis, of Canandaigua; Miss Mabel King Hill, of Walden; Miss Florence Bochlovitz, of Albany.

The Starling Medical College, of Columbus, O., graduated the following on May 5th:

Charles H. Hoffhine, of Columbus; William R. Bebout, of Wheeling, W. Va.; Lewis H. Britton, of Gambier; Allen Coburn, of Becketts; Ernest L. Crum, of Tiffin; Ralph W. Dawson, of East Liverpool; Charles A. Finefrock, of Prospect; Felix C. Harman, of Glandorf; Carl W. Cooper, of Marysville; Jasper W. Jolley, of Richwood; Benjamin R. Kirkendall, of Derby; Carl R. Noble, of Galion; Charles H. Kramer, of Pickerington; H. Burr Larimore, of Danville; Clarence S. Latham, of Hilliards; Charles P. McKee, of St. Marys; Robert B. McLaughlin and John M. Morse, of Resaca; Guy E. Noble and Clarence E. Northrup, of McConnelville; Ewing D. Piper, of Bethesda; Charles L. Reasoner, of Hartford City, Ind.; Edward B. Roller, of Green Castle; Joseph S. Shinn, of Christiansburg; Harry A. Shisser, of Dayton; Ralph H. Smith, of Lancaster; J. Omar Stout, of Lithopolis; Vogt G. Wolfe, of DeGraff.

Tulane University, New Orleans, has graduated the following in medicine:

F. F. Blair, W. A. Blair, P. W. Bohne, A. H. Borey, W. A. Boyce, Jr., W. H. Brent, R. E. Chalker, F. Champenois, A. L. Chapman, J. S. Chisolm, L. O. Clark, H. Clarke, H. C. Cole, E. D. Craft, L. B. Crawford, N. B. Dean, F. M. Douglass, J. W. DuVal, J. M. Ehler, J. B. Farrior, J. W. Linley, W. D. Fonville, Jr., J. P. Frellsen, F. Z. Goss, W. P. Gray, G. L. Gresham, R. A. Grigsby, R. B. Hagood, F. Hamilton, C. B. Harrington, M. D. Haspel, C. H. Herbert, R. A. Herring, S. L. Hollingsworth, G. Holmes, C. E. Hutchinson, W. B. Johnson, S. E. Jordan, S. N. Jordan, P. J. Kahle, O. E. J. Kauffmann, R. A. Kearny, H. L. Lazar, V. A. Lea, E. L. Leckert, L. F. Magruder, E. W. Mahler, Jr., J. R. Mahone, Jr., L. E. Martin, J. L. Mitchell, J. S. Muller, M. L. Nance, Jr., A. K. Naugle, J. H. Norman, Jr., J. T. Palmer, S. J. Pate, W. E. Pelham, Jr., J. H. Petty, J. W. Plauché, J. F. Pou, Jr., J. O. Pratt, R. B. Pryor, M. E. Quina, E. J. Riche, C. H. Rulfs, G. O. Sanders, T. E. Sanders, T. R. Sartor, J. A. Sewell, H. R. Shands, J. A. Slack, J. A. Sperry, C. W. Sutton, J. B. Thigpen, P. B. Salatch, C. A. Thomas, R. D. Tompkins, P. W. Toombs, R. W. Vincent, C. A. Wallbillich, M. Williams, J. W. Wilson, O. P. Wise.

Detroit College of Medicine.—The following graduated from this college on May 4th:

Frank E. Allison, Hugh H. Angle, Norman Balfour, Ernest G. Bellinger, William H. Betteys, Lewis E. Bracey, Julian Branch, Clark D. Brooks, Eugene S. Browning, A. Ernest Bruce, Frederick G. Buesser, George C. Chene, Floyd W. Clements, secretary; William F. Clute, Berten M.

Davey, Herbert L. Eastman, Eugene F. Fontaine, Robert C. Fraser, Philip I. Froude, Dugald A. Galbraith, Samuel S. Hackwell, George B. Henderson, Neal L. Hoskine, Guy D. Houghton, John S. Jackson, Byron H. Jenne, treasurer; Azariah K. Jewell, Hubert H. Johnson, Oren G. Johnson, Herman C. Kiehl, David J. Lackie, Ingol M. Law, president; Harold P. Lawrence, Henry A. Luce, Charles D. Mohler, Vaughan G. Morris, Joseph S. Morrison, Archibald D. McAlpine, Nelson McArthur, Gustave L. McClellan, Joseph A. McCarvah, Zachariah T. Nairn, George O. Pratt, George Wilford Robinson, Clyde C. Simons, Victor H. de Somokeyo, valedictorian; Charles R. W. Southwick, Clarence T. Starker, John D. Stewart, Maitland N. Stewart, L. A. Traphagen, George W. Trumble, Joseph E. Wellman, Harmon C. Wolie.

An Appeal for the Poor of Labrador.—We have received the following letter, which tells its own story:

NEW YORK, April 27, 1905.

DEAR SIR:

That Dr. Wilfred T. Grenfell, who is engaged in a mercurial work for the deep sea fishermen of Labrador, has won the interest of a large number of Americans, is evident from the prominence given in the press to reports that amounts varying from \$60,000 to \$100,000 have been contributed to the Labrador Medical Mission as a result of his lectures in this country this spring. All friends of Dr. Grenfell wish these reports were true. As a matter of fact, the response to Dr. Grenfell's stories of these fishermen's life has indeed been both kind and prompt; but the amount which has been raised this year is in round numbers only about \$12,000. There is immediate need for noble that sum.

The fact that Dr. Grenfell cannot at the same time be setting broken bones, amputating frozen feet, curing diseases, directing cooperative stores, driving dog teams, and competing generally with grog boats, unscrupulous traders, and Arctic weather in Labrador, and raising funds in the United States, has led a number of his friends to form The Grenfell Association. On the Board of Directors are the following gentlemen: Henry Van Dyke, D. D., LL. D., D. Bryson Delavan, M. D., Eugene Delano, Stephen Baker, S. Edgar Briggs, William Adams Brown, D. D., William Adams Delano, Richard Henry Derby, M. D., Arthur Curtiss James, Frederic S. Lee, Hamilton W. Mabie, LL. D., Leighton Parks, D. D., Herbert L. Satterlee, Francis Lynde Stetson, A. Alexander Smith, M. D.

Membership in the association, for one year, is open to any one who will send, with name and address, two dollars to Eugene Delano, treasurer, 59 Wall Street, New York. To the treasurer also may be sent any additional contributions for the work of Dr. Grenfell. An accounting of the money thus raised will be rendered in an annual report.

Inasmuch as Dr. Grenfell receives contributions from a variety of sources, it has been decided, with Dr. Grenfell's hearty approval, to devote the money raised by The Grenfell Association preferentially to the hospital and allied enterprises at Battle Harbor. This will enable Dr. Grenfell not only to increase greatly the facilities in that place, but also to deflect money from other sources to the improvement of hospital service elsewhere in Labrador.

Very truly yours,

ERNEST HAMLIN ABBOTT,

Secretary of The Grenfell Association.

287 Fourth Avenue, New York city.

Personal.—Dr. C. E. Caldwell, of Cincinnati, was severely injured on May 5th by colliding with a steel post while he was standing on the step of a trolley car.

The board of trustees of the Ohio Medical University have elected officers and members of the faculty. There were a number of changes, either by retirement or addition, and by promotion. Dr. William Laurens Dick, professor of orthopaedic surgery, retired because of removal from the city. Dr. McKendree Smith retired because of his inability to give his chair the required attention. Dr. James W. Wellons, clinical assistant to chair of ophthalmology, retired because of the press of other matters that required his at-

tention. There were added to the corps of teachers, Dr. W. A. Dodd, instructor in orthopaedic surgery; Dr. J. J. Coons, assistant to chair of practice; and Dr. C. D. Shepard, instructor in dermatology. There were a number of promotions. Dr. Charles W. McGavran, from instructor, was made professor in physical diagnosis; Dr. William D. Inglis, from assistant, was promoted to professor of obstetrics; Dr. John A. Reibel was made professor of genitourinary diseases, a promotion from assistant; Dr. Ira Jacob Mizer was promoted to instructor in dietetics, a promotion from assistant to the chair of the practice of medicine. Dr. George H. Matson, professor of materia medica, was also made assistant to the chair of therapeutics.

Dr. G. C. Chene, of Windsor, and Dr. G. W. Robinson, of Scarboro, Ont., have been appointed to the staff of house physicians of St. Mary's Hospital, Detroit, succeeding Dr. L. L. Zimmer and Dr. William J. Seymour, whose terms have expired. Dr. C. H. McLean is head surgeon.

The faculty of the Maryland Medical College has appointed as resident physician at the Franklin Square Hospital for the ensuing year Dr. Walter Alva Weed, of Alabama. Dr. Newton I. Parr has been appointed first assistant and Dr. Cirilo L. Rodriguez second assistant. The new residents are members of this year's graduating class.

West Virginia State Medical Association.—At the thirty-eighth annual meeting of this association, to be held at Wheeling, May 24th, 25th, and 26th, it is expected that the following papers will be read:

The Teachings of Failures, by Dr. F. L. Hupp, of Wheeling; The Palliative Treatment of Prostatic Hypertrophy, by Dr. H. E. Sloan, of Clarksburg; Preoperative and Post-operative Treatment of Surgical Cases, by Dr. J. E. Cannaday, of Paint Creek; Appendiceal Abscess—Pathology and Treatment—Report of Cases, by Dr. S. M. Mason, of Clarksburg; Injuries of the Head—Report of Cases, by Dr. Henry P. Linsz, of Wheeling; Anatomical and Physiological Principles Involved in the Symptomatology of Brain Traumatism, by Dr. J. Schwinn, of Wheeling; Office Treatment of Rectal Diseases, by Dr. William M. Beach, of Pittsburgh; "Symposium" on Pneumonia: Aetiology, by Dr. S. S. Wade, of Morgantown; Pathology, by Dr. L. O. Rose, of Parkersburg; Symptoms and Signs, by Dr. W. W. Tompkins, of Charleston; Treatment, by Dr. L. D. Wilson, of Wheeling; Tuberculosis, by Dr. J. W. Preston, of Keystone; Pseudomembranous Croup, by Dr. S. W. Bush, of Parkersburg; Cases and Experiences of Interest, by Dr. W. H. Sharp, of Parkersburg; Diseases of the Kidneys, by Dr. M. McNeilan, of Parkersburg; Rupture of the Bladder, by Dr. J. R. Cook, of Fairmont; The Importance of Early Diagnosis of Intraocular Lesions, by Dr. H. R. Johnson, of Fairmont; Fikker's Diagnosticum, by Dr. L. O. Rose, of Parkersburg; Drugs and the Diazo Reaction—A Communication, by Dr. William W. Golden, of Elkins.

In addition to the papers, the titles of which are published, a number of valuable contributions have been promised and will be read under the head of "voluntary papers." The exhibition of interesting cases and pathological specimens, and the demonstration of new methods of diagnosis and treatment are always welcome at the annual meeting. As a special feature of this meeting arrangements are being made for daily clinics, medical and surgical, to be held at the City and the North Wheeling Hospitals.

A Special Party Organizing to Attend the Next Meeting of the American Medical Association.—

In order that the trip to the meeting of the American Medical Association at Portland, Ore., this year, may be enjoyed by the largest possible number of physicians and surgeons, and particularly by those whose professional duties make it necessary that the journey be performed in an expeditious manner, a special overland limited train has been arranged for, and a special party is being organized to leave Chicago via the Chicago, Union Pacific and Northwestern Line the evening of July 6th, to make the trip to Portland surrounded by every luxury that modern travel can provide, upon schedules occupying a little less than seventy hours en route. It is not often that so congenial a party is possible, traveling under such highly favorable surroundings for comfort and enjoyment of the trip. Our readers are most cordially invited to become members of the party. Arrangements have been made with the railways for the movement of this special overland limited train without any extra charge for the unusual service thus secured. The round trip rate Chicago to Portland and return is \$56.50, and proportionately low rates from other points will be in effect. Ask your ticket agent for your tickets via the Chicago and Northwestern and Union Pacific lines. Return trip may be made via Oregon Short Line, Salt Lake City, and through Colorado without extra charge, or via the Northern Pacific, Great Northern, or Canadian Pacific without extra charge, or via San Francisco and Los Angeles on the payment of \$11.00 additional at time of purchase. Sleeping car rate Chicago to Portland for double berth in special train, \$14.00; drawing room, \$53.00. Stop overs will be permitted at and west of Colorado common points, Cheyenne, or Trinidad, inclusive, or St. Paul and Minneapolis and a tour of the Yellowstone Park may be made either via Monida or Livingston at a rate of \$49.50 additional, covering the usual tour through the park, including stage transportation and hotel accommodations. Our readers will please advise Mr. H. A. Gross, General Agent Passenger Department, Chicago and Northwestern Railway, 212 Clark Street, Chicago, Ill., whether they desire to be included in the party, and how much sleeping car space they desire reserved. Further information in regard to the trip will be cheerfully furnished on application by Dr. S. C. Stanton, room 1609, 59 State Street, Chicago; Dr. Heinrich Stern, 56 East Seventy-sixth Street, New York; Dr. Lewis S. McMurtry, Louisville, Ky.; Dr. William Warren Potter, Buffalo; Dr. Florus F. Lawrence, Columbus, O.; Dr. Simon P. Scherer, Indianapolis, Ind.; or Dr. Charles A. L. Reed, Cincinnati, O.

Connecticut Medical Society.—At the one hundred and thirteenth annual meeting of this society, to be held at Hartford, May 24th and 25th, it is expected that the following papers will be read:

Report on the Progress of Medicine, by Dr. D. C. Brown, of Danbury, and Dr. J. C. Lynch, of Bridgeport; Report on the Progress of Surgery, by Dr. C. C. Godfrey, of Bridgeport, and Dr. B. Austin Cheney, of New Haven; Report of the Committee on Matters of Professional Interest in the State—Cerebrospinal Meningitis, by Dr. F. A. Morrell,

of Putnam; Dissertation—The Use of Laboratory Aids in Diagnosis, by Dr. C. J. Bartlett, of New Haven; Gastric Ulcer, by Dr. H. M. Lee, of New London; Carcinoma of the Stomach, by Dr. E. F. McIntosh, of New Haven; The Diagnosis of Surgical Diseases of the Kidney and Ureter, by Dr. Oliver C. Smith, of Hartford; Report of a Case of Adenoma of Kidney, Nephrectomy, Recovery, by Dr. J. B. Boucher, of Hartford; The Bossi Dilator for Rapid Dilatation of the Cervix, by Dr. Otto G. Ramsay, of New Haven; Pregnancy in Malformations of the Uterus, with Report of Cases, by Dr. C. E. Taft, of Hartford; Some of the Newer, Non-Surgical Forms of Treatment of Female Pelvic Disorders, by Dr. Kate C. Mead, of Middletown; The Prevention of Venereal Diseases, by Dr. R. A. McDonnell, of New Haven; Notes on Surgery of the Brain, by Dr. H. G. Howe, of Hartford; The Faucial Tonsil, by Dr. F. S. Crossfield, of Hartford; Some Remarks on Adenoid Hypertrophy Occurring in Children, by Dr. E. T. Smith, of Hartford; Alcohol as a Remedy in Disease, by Dr. T. D. Crothers, of Hartford; Chloroform Anæsthesia, by Dr. T. G. Sloan, of South Manchester; The Use of Cocaine in Surgery, by Dr. Richard F. Rand, of New Haven; An Easy, Efficient and Rational Method of Reducing Recent Dislocations of the Shoulder Joint, by Dr. E. C. Chipman, of New London; The Diagnosis and Treatment of Pronated Feet, by Dr. Allen H. Williams, of Hartford; Skin Grafting, by Dr. A. A. Crane, of Waterbury; The President's Address, *Résumé* of the Development and Present Status of Gastric Surgery, by Dr. William H. Carmalt, of New Haven; A Contribution to the Study of Dysentery, by Dr. A. R. Diefendorf, of Middletown; Acute Intestinal Obstruction; Resection of Four Feet of Intestine; Recovery, by Dr. Daniel F. Sullivan, of Hartford; Radical Operation for Mammary Carcinoma, by Dr. W. F. Verdi, of New Haven; The Treatment of Malignant Disease, Including a Report of Over One Hundred Cases Permanently Cured by Surgical Operation, by Dr. F. S. Dennis, of Norfolk; The Purpose of the Gaylord Farm Sanatorium and Its Relation to the State, by Dr. J. P. C. Foster, of New Haven; The Need of Popular Education in the Tuberculosis Problem, by Dr. F. T. Simpson, of Hartford; Prophylaxis in Tuberculosis, by Dr. C. D. Alton, of Hartford; Tuberculous Diseases of the Spine, by Dr. E. H. Arnold, of New Haven; The Treatment in Tuberculous Joint Disease, by Dr. Joseph E. Root, of Hartford; Infant Feeding with Cow's Milk, by Dr. H. Merriman Steele, of New Haven; On the Medical Treatment of Gallstones, by Dr. E. M. Goodenough, of Waterbury; Pathological Variations and Diagnosis of Diseases of the Gall Bladder, by Dr. N. R. Hotchkiss, of New Haven; Medical Treatment of Diseases of the Gall Bladder, by Dr. F. G. Graves, of Waterbury; Surgical Treatment of Diseases of the Gall Bladder, by Dr. E. W. Smith, of Meriden; A Question in Gall Bladder Surgery, by Dr. H. F. Brownlee, of Danbury; Hemorrhoids: Anatomy and Pathology, by Dr. A. J. Wolff, of Hartford; *Ætiology*, Diagnosis, and Prognosis, by Dr. A. S. Brackett, of Bristol; Medical Treatment, by Dr. A. E. Abrams, of Hartford; Surgical Treatment, by Dr. E. P. Swasey, of New Britain; Appendicitis, by Dr. W. J. Tracey, of Norwalk; A *Résumé* of a Few Operations in Regional Surgery, by Dr. J. Reed Topping, of Bridgeport; Dangers of Delay in Abdominal Lesions, by Dr. O. C. Smith, of Hartford; The Significance of Albuminuria, by Dr. F. C. Hyde, of Greenwich; Some Severe Forms of Stomach Disease, with Selected Cases, by Dr. E. F. McIntosh, of New Haven; Preventive Medicine from the Standpoint of Water Purification, by Dr. W. S. Randall, of Shelton; Post Partum Hemorrhage, by Dr. J. F. Hayes, of Waterbury; Parotiditis as a Complication in Typhoid Fever, by Dr. C. J. Foote, of New Haven; Local Treatment of Neuroses of the Respiratory Organs, by Dr. H. L. Swain, of New Haven; Tuberculous Laryngitis, by Dr. F. S. Crossfield, of Hartford; Eye Injuries, by Dr. H. S. Miles, of Bridgeport; Local Anæsthesia by Injections of Sterile Water, by Dr. F. W. Stevens, of Bridgeport; The Doctor Without Covers, by Dr. F. Schavoir, of Stamford; The Influence of the Medical Practitioner in the Prevention of Defective Children, by Dr. George H. Knight, of Lakeville; Empyema, by Dr. E. J. McKnight, of Hartford; Pneumonia, by Dr. J. F. Dowling, of Hartford; Diagnosis of Joint Affections, by Dr. A. H. Williams, of Hartford; The Care of the Genitalia of the Young Man, by Dr. E. J. McKnight, of Hartford; Our Physical Reserve, by Dr. J. B. McCook, of Hartford; Infant Mortality, by Dr. C. A. Goodrich, of Hartford.

Path of Current Literature.

LYON MEDICAL.

April 9, 1905.

1. Intermittent Dropsy of the Gall Bladder from Calculus in the Cystic Duct, By EUGENE VILLARD.
2. Protection of Infants, By HORAND.
3. Purulent Pleurisy Complicating Pneumonia; Empyema; Abscess of the Wall; Recovery, By L. CADET.

1. Intermittent Distention of the Gall Bladder.—Villard reports a case of this nature met with in a woman 36 years of age, who suffered severely from biliary colic. A laparotomy was performed and the gall bladder found of normal size, not distended, and not adherent to the surrounding tissues. No calculus could be felt within the viscus, and the abdominal wound was accordingly closed. There were no attacks of colic for several days, but they then recurred with as great severity as ever. A second laparotomy was performed six weeks after the first, when the gall bladder was found to be much distended. After cholecystotomy a very small calculus was found in the cystic duct.

2. Care of Infants.—Horand continues his paper on this subject with an account of the provisions adopted by various cities to check the ravages of gastroenteritis, including the establishment of societies at Lyons with regard to infant feeding.

3. Purulent Pleurisy.—Cadet reports a case of pneumonia of the left lung in a man 26 years old, followed by pleurisy, empyema, and the formation of an abscess in the chest wall. The patient recovered.

April 16, 1905.

1. The Use of Plates of Blood Agar in Obstetric Practice, By FABRE and AMSTAD.
2. Protection of Infants at an Early Age, By Dr. HORAND.
3. Immediate and Remote Results of Surgical Intervention in Biliary Lithiasis, By GASTON COTTE.

1. Blood Agar in Obstetrics.—Fabre and Amstad claim that by the method they describe the presence of the streptococcus pyogenes, the most frequent excitant of puerperal fever, is readily detected, and that by its means one is enabled to separate the gracilis from the group of streptococci, which is important, as this microorganism is not active in the production of puerperal fever. The technics of the method is simple to any one accustomed to bacteriological research.

2. Protection of Infants at an Early Age.—Horand presents the final installment of his paper on this subject, and finally sums up the requirements for the proper care of infants thus: 1. For the mother, quiet for a certain time before and after confinement. 2. Maternal nursing should be obligatory except in cases where it is absolutely impossible. 3. Sufficient aid for the mothers who are nursing. 4. An organization in each district to look after nutriment, with distribution of sterilized milk. 5. The increase of day nurseries and the creation of places where babies can be cared for within the reach of all purses. 6. The organ-

ization of maternal associations. 7. The assistance, without distinction, of all needy mothers, whether married or single, and of illegitimate as well as legitimate children.

3. Biliary Lithiasis.—Cotte's article is really a review of a recent German work on the technics of operations for gallstones.

SEMAINE MEDICALE.

April 5, 1905.

Asthénia,

By Dr. P. LONDE.

Asthénia.—Londe defines asthenia as an impossibility of, or at least a difficulty in making a muscular effort, particularly if prolonged. This condition may be general or local. General asthenia may be subjective or objective. The prostration of acute diseases, such as typhoid fever, acute peritonitis, or Addison's disease, is an example of the objective form, while the less strongly marked weakness which accompanies infection or chronic poisoning is an example of the subjective. The aetiological conditions are: 1. Infections, autointoxications, intoxications; 2. abdominal diseases; 3. central nervous lesions; 4. neuroses and psychoses. Sometimes the asthenia is of cerebellar origin, more often of visceral and abdominal, or sympathetic origin. In a great variety of diseases, peritonitis, Addison's disease, grippe, diabetes, mucomembranous enteritis, exophthalmic goitre, melancholia, etc., the sympathetic is at fault as is shown by the frequent association of vasomotor or secretory troubles. This has also been confirmed by experiment. The author also believes that there are anatomical relations between the cerebellum and the sympathetic which explain their physiological and pathological associated actions. By localized asthenia is meant asthenia predominating or confined to one place, as in chronic nervous dysphonia, accommodative asthenopia, and perhaps nocturnal incontinence of urine in children, which is a bulbospinal asthenia.

PRESSE MEDICALE.

April 15, 1905.

1. Cutaneous Ankylostomiasis, By W. DUBREUILH.
2. Drink, Qualitatively and Quantitatively Considered in Healthy and Sick People, By H. LABBÉ.

1. Cutaneous Ankylostomiasis.—Dubreuilh has collated the literature which goes to show that the disease known as "ground itch" is caused by various forms of ankylostoma, the larvæ of which are to be found in the soil.

2. Drink.—Labbé uses the word drink as an expression of a physiological necessity of constant recurrence. Only one liquid is physiologically necessary, water, and this forms the basis of all drinks, which he divides into three classes: 1, Water either pure or containing sugars and aromatics; 2, saline waters, containing a larger or smaller amount of mineral matter; 3, water containing alcohol in greater or less proportion. All drinks after passing the intestinal epithelium are incorporated in the blood, and the value of each is to be determined from a comparison of its osmotic pressure with that of the blood cells. Every drink must therefore be hypotensive, iso-

tensive, or hypertensive. Ordinary water is usually hypotensive. The same is true of sweet drinks, drinks made from fruits, such as lemonade, and syrups in their usual concentration. The other classes are hypertensive in their action. They cause a concentration of the blood serum, and equilibrium is reestablished by drawing the necessary water from the blood and tissue fluids of the body.

REVUE DE CHIRURGIE.

April, 1905.

1. Foreign Bodies in the Joints, Especially Those of Traumatic Origin, from an Experimental and Histological Point of View, By CORNIL and COUDRAY.
2. Concerning Carotid Aneurysms, By MENDES.
3. Gastrorrhagia in Connection with Simple Ulcer of the Stomach, By TUFFIER and JEANNE.
4. Intestinal Hæmorrhage Following Operations for Hernia, By SAUVÉ.
5. Functional Impotence Following Traumatism of the Joints, By MALLY and RICHON.

1. **Foreign Bodies in the Joints.**—Cornil and Coudray report the following conclusions: 1, Experimental traumatic bodies do not always remain free in the joints; they may become attached to the bony skeleton or to the synovial membrane; 2, pathological osteocartilaginous bodies: These bodies appear to originate from an ecchondriosis which is similar to the lesions of dry arthritis; 3, tuberculous sequestra simulating traumatic foreign bodies. These bodies are often found at the lower extremity of the femur, and often upon the internal condyle. They are often attached to the condyle. They are often flattened in form, are similar to traumatic bodies, and are constituted from osteoarticular fragments of the condyles.

2. **Concerning Carotid Aneurysms.**—Mendes states that the objection raised by most surgeons to the extirpation of the sac of carotid aneurysms is the difficulty of its dissection. This may be a valid objection, for there may be dense adhesions, very firm tissues, and important nerves which cannot easily be turned aside. These obstacles are seldom insurmountable, especially since the carotid itself, according to this method of operating, has already been ligated. A portion of the sac may be left if necessary. Seven cases of extirpation have been reported, in all which the result was satisfactory. The operation is curative of existing evils and preventive as to subsequent ones. The ordinary accidents from simple ligation are inflammation, suppuration, and hæmorrhage. It may also result in syncope, headache, convulsions, delirium, and hemiplegia, and these accidents often lead to a fatal result. Aphasia, dyspnœa, cough, and bronchitis are also frequent consequences. The conditions in a carotid aneurysm are such that the author doubts the advisability of an operation in those who have passed their sixtieth year. Extirpation of the sac is believed by him to be the operation of choice for the lesion in question.

4. **Intestinal Hæmorrhage Following Operations for Hernia.**—Sauvé draws the following conclusions: 1, The intestinal hæmorrhage which is

under consideration may be either arterial or capillary. In the hæmorrhages which occur soon after operation, ischæmia which follows strangulation of the intestine has produced structural change in the arterioles. The same is true for the deferred hæmorrhages which follow arterial thrombosis; 2, venous thrombosis is not a cause for such hæmorrhages, so far as is known, and it would seem to be contrary to physiological facts; 3, the treatment for this form of enterorrhagia depends upon the conditions; hæmorrhage from faulty operative procedures, of course, ought never to occur. If the hæmorrhage occurs soon after operation and is not excessive, ice and opium will suffice to keep the intestine quiet, and recovery is almost certain. If the hæmorrhage occurs late and is profuse one must be guided by the nature of the bloody stools, and by the pulse. If the stools contain sloughy débris and are of very repulsive odor, and the peritonæum has not been seriously injured, ice, opium, and ergotine will usually give favorable results. If the stool is composed of pure blood and the pulse is rapid, the choice will lie between medical treatment, expectancy, and resection of the intestine. The last, under the conditions which are present, does not promise brilliant results.

REVUE DE MEDECINE.

April, 1905.

1. Classification and Pathogenic Value of Orthostatic Albuminuria, By TEISSIER.
2. The Metabolism of Water and of the Chlorides, By LABBÉ and MORCHOISNE.
3. Neuropathic Aureolas, By FERÉ.
4. Habitual Physiological Oliguria, By COTTET.

2. **The Metabolism of Water and of the Chlorides.**—Labbé and Marchoisne offer the following propositions: 1, Though there is a nitrogenous equivalent in the daily elimination which can be readily and accurately determined, from day to day, there is no similar equivalent of chlorides in healthy individuals. There may, however, be an average equivalent of chlorides calculated from a sufficient number of days, which, however, is quite variable. The regulation of the ingesta will lead to the regulation of that which is eliminated; 2, the equivalent of water cannot be obtained with accuracy, but can be determined with about the same relative accuracy as is the case with the chlorides; 3, with an unrestricted diet the ingestion of water is directly influenced by the ingestion of chloride of sodium; 4, in a healthy normal individual, with whom the ingestion of water and of salt is regulated, there is almost uniformly a concentrated condition in the urine, as to chlorides; 5, the relation of the elimination of water to that of chlorides should be fairly constant in a healthy individual from day to day; 6, the daily weight of a healthy individual is consequently variable, but such variations are reduced to a minimum in those in whom the ingestion of chlorides and of water are carefully regulated; 7, in order to determine the elimination of chlorides in those who are more or less in a pathological condition, they must be rigidly submitted to a diet which is carefully determined, as to quan-

tity and quality, and which is fixed as to chlorides.

4. **Habitual Physiological Oliguria.**—Cottet insists that the urinary function should be carefully observed, not alone during disease, but also during health. Habitual oliguria, especially in those who have by heredity a gouty diathesis, becomes the more dangerous as it is repeated from day to day, and as it is overlooked until accidents result which cause it to be conspicuous. This condition should be observed at the beginning and should be corrected as promptly as possible. Simple hygienic or therapeutic measures may be all that would be required at this stage.

FORTSCHRITTE DER MEDIZIN.

April 10, 1905.

1. Diseases of the Joints in Connection with Hæmophilia, By ZESAS.
2. The Germ Cell Theory of Cancer, By GRÜNBAUM.

2. **The Germ Cell Theory of Cancer.**—Grünbaum states that the explanation of the origin of malignant tumors has come nearer by means of two remarkable discoveries: 1, The demonstration of the morphological continuity of the germ cells; 2, the discovery of heterotypic mitosis in malignant tumors. Until recently it was believed that the sexual cells in the embryo came from a layer of peritoneal epithelium in the blastoderm, but that they did not differ in any respect, in their origin from the other cells of the embryo. Beard has demonstrated the morphological continuity of the germ cells, and confirmed the hypothesis of an antithetic exchange of generation in the human being. This hypothesis briefly is that after the union of the spermatozoon and ovum the chorion is formed by the division of the united cells, corresponding to a larva or trophoblast. From one of these cells are formed a number of spores. One of the spores at length becomes the embryo and absorbs the other spores which become its sexual cells. In other words, they are not formed from the embryo, but the embryo serves as a home for them. Concerning their particular position in the embryo these germ cells may wander and in a few days may be found in various locations. According to Beard they may serve as the origin of a cancerous tumor, though he prefers to regard them as a developed and undeveloped embryo from the same cell. The proof of the connection between germ cell and malignant tumor is advanced by Fanner and others. They have discovered a kind of cell division in malignant tumors which occurs normally only in germ cells. One of the distinguishing features of this heterotypic mitosis is the formation of only half the normal number of chromosomes by means of the subdividing cells. These and other characteristics are also observed in the cells of myelogenous tumors. There must therefore be something in common between germ cells and tumor cells. In benign tumors this form of cell division could not be found. This deficiency forms the real difference between the two types of tumors. This strengthens the view that there is no fundamental difference between benign and malignant tumors. We know that one form can

pass clinically into the other. Heterotypic mitosis does not occur suddenly in the evolution of sexual cells. In the testicle it is not found prior to the third division, and the same is true of the ovary. The membrana granulosa then begins to proliferate and the discus proligerus is formed, this being a proof of their non-somatic origin. In the same way heterotypic mitosis cannot occur in tumors during the stage when they are not malignant. Why this change should occur suddenly is not more remarkable in the case of a tumor than in the case of the testicle and ovary. In a given cell or cells of potential growth it does not seem improbable that the toxine of a parasite, the brief irritation of traumatism, the persistence of a chronic irritation, or the chemical conditions of a disturbed metabolism would be sufficient to dissipate their energies, and thus a sufficient number of causes would act to produce a given result.

April 20, 1905.

1. Appendicitis and Erythema Exudativum Multiforme, By CHENOWETH.
2. The Results of Operations for Appendicitis, By TREVES.
3. The Treatment of Chronic Pruritus Ani, By BALL.

1. **Appendicitis and Erythema Exudativum Multiforme.**—Chenoweth says the eruption of this disease may be the first and only expression of disease, or there may be debility, headache, pain in the back, gastric disorder, and fever. There may also be visceral lesions, the lungs, brain, kidneys, stomach, and intestine being involved. Not infrequently there is colic, nose-bleed, fever, hæmaturia, hæmatemesis, or intestinal hæmorrhage. The appendix is concerned more frequently than is usually supposed. Colic with abdominal crises of erythema may suggest the diagnosis of appendicitis when this disease does not really exist. Or the disease of the appendix may be overlooked until the more serious symptoms become manifest. The position of the appendix, the abundance of its lymphatic tissue under a thick layer of fibromuscular tissue, and its terminal circulation make it an inviting object for circulation disturbances. The diagnosis of appendicitis is based upon pain, swelling, and muscular rigidity, the last being absent when erythema is present. Two cases are reported in which the pathological condition of the appendix was determined both clinically and microscopically, and was associated with the lesion of the skin. The skin disease returned after the appendix had been removed. It is not asserted that appendicitis is dependent upon the erythematous condition of the skin, but the former is a visceral manifestation of this disease.

2. **The Results of Operations for Appendicitis.**—Treves gives statistics of 45 incomplete operations for appendicitis during the interval period. In 2 there was incomplete removal of the appendix, in 9 there was coexisting ovarian disease, in 8 cases of colitis, in 7 persistent local pain, in 5 neurasthenia or hypochondria, in 3 attacks of gallstone colic, in 2 intestinal colic, in 2 movable kidney, in 1 renal calculus, in 1 the cause was obscure, in 5 there was tumor in the right iliac fossa. In a second group of cases in which a perityphlitic

abscess was opened there was persistent inflammation in forty per cent., recurrent abscess in twenty-four per cent., recurrent attacks of appendicitis in sixteen per cent., fecal fistula in twelve per cent., inflammatory deposits in the iliac fossa in eight per cent. In all, the statistics of 1,000 operations are given, 364 of which were performed during the interval period with 4 deaths; during an attack there were 39 cases with localized peritonitis, but without suppuration, with 5 deaths; there were 431 cases with abscess, with 35 deaths; there were 166 cases with general peritonitis, with 127 deaths. Of complications in the 1,000 cases, there were 49 fecal fistulae, 12 thromboses of the femoral vein, 10 cases of intestinal obstruction, 17 of bronchopneumonia, 14 of pleurisy with effusion, 2 of dry pleurisy, 7 of empyema, 4 of acute bronchitis, 1 of pulmonary embolus, 4 of non-suppurative parotiditis, 4 of pyelophlebitis, 11 of residual abscess, and 12 of secondary abscess. Six of the cases were in pregnant women.

3. The Treatment of Chronic Pruritus Ani.—

Ball believes that cauterization and excision of the skin, in cases in which there is chronic irritation, but no dermatitis, is rough, irrational, and unscientific practice. There are usually trophic changes in the skin in such cases which are caused by changes in the sensitive nerves. In some cases there may be dermatitis at the beginning which may disappear, though the local condition may become worse. In other cases inflammation may be caused by the scratching. Should a case become obstinate the author recommends the excision of the posterior roots and ganglia of the third and fourth sacral nerves, or since this might affect the integrity of the sphincters of the rectum the ends of the sensitive nerves in the affected area might be divided instead. A curved incision is made on either side of the anus, including the diseased area, forming an ellipse, the skin at either extremity of which, however, is not cut. The skin is then dissected away and the nerve endings divided. The wound is then closed and the itching will cease. Should it return the nerve ganglia can be excised.

RIFORMA MEDICA.

April 8, 1905.

1. The Passage of Agglutinins and Tuberculosis Antitoxines Into the Milk, and Their Absorption Through the Gastrointestinal Tract, By F. FIGARI.
2. Some Points on the Medical and Surgical Treatment of Pott's Disease, By ARTURO CAMPANI.
3. Family Lateral Amyotrophic Sclerosis, and Pellagra, By ARMANDO TESTI.
4. The Ocular Disturbances of General Paralysis, as Compared to Those of Locomotor Ataxia, By CESARE MANNINI.

1. Antitoxine in Milk of Animals.—Figari found that the agglutinins and antitoxines of tuberculosis appeared in the milk of cows and goats that had been actively immunized, and of rabbits which had been passively immunized against the disease. Young goats born of immunized mothers inherit the defensive properties

of the mothers, and continue to receive defensive substances as long as they nurse. Calves and young goats born of non-immunized mothers are not only capable of absorbing agglutinins and antitoxines of tuberculosis with the milk of immunized animals taken into the stomach, but are able at the same time to produce additional defensive substances in their own organisms. Rabbits passively immunized either by subcutaneous injections, or by the gastric route, by the administration of immunized milk are capable of transmitting to their young, by means of their milk, the tuberculous agglutinins and antitoxines which they possess. Adult rabbits fed on the milk of immunized cows also absorb, through their stomachs, the agglutinins and antitoxines of tuberculosis, and their serums are capable of producing agglutinating and antitoxic effects.

2. Treatment of Pott's Disease.—Campani, in speaking of the non-surgical methods in treating Pott's disease, says that the old routine of giving codliver oil and iodides is not to be commended, as it does not give good results, and is apt to produce disturbances of digestion. He prefers, above all, the use of hydrotherapy in the form of cold sponging. This method increases the appetite, promotes nutrition, and the general development of the child, as well as the formation of new blood cells. In five cases reported, he came across abscesses, of which one healed spontaneously; one had to be opened widely, and the rest were punctured by means of Plessi's cannula. In all cases local healing followed. He prefers puncture with lavage of the cavity to all other methods of treating abscesses of Pott's disease. The operation is easy and harmless. The antiseptic fluid to be used should be mild, such as salicylic acid, one part in a thousand. The pressure to be employed in injecting it should be sufficient to distend the walls of the sac. He thinks that injections of iodine, iodoform, oil, etc., are useless. Hydrotherapy acts not only by its antiphlogistic effect, but also by its special stimulating effects on the spinal nerve roots. The author thinks that it should be used always in Pott's disease, except in those acute cases in which there is high fever and great pain, and in which immobility is demanded.

ROUSSKY VRATCH.

April 2, 1905.

1. What is a Healthy Normal Child? By A. O. KARNITZKI.
2. The Influence of Uresin (a Dilithium Citrate of Urotropin) on Uric Acid and Its Salts, By L. G. SPASSKI.
3. A Case of Fibrinous Pneumonia Which Ended Favorably in the Presence of a Marked Leucopenia, By V. F. PETROFF.
4. A Case of Typhus Fever in a Child Five Months Old, By P. P. EMINETT.
5. A Case of Abnormally Located Cecum, with a Common Mesentery, By D. S. MOROSOFF.

1. What is a Healthy Normal Child?—Karnitzki says that we do not know what a healthy normal child is. Studies in child physiology have

not been made with sufficient accuracy as regards the normal weight and development of children. The author reports a series of observations which he made upon his own children from birth to the seventeenth year. In order to gain a clear idea of what really constitutes a healthy normal child it would be necessary to study for a number of years a series of children born and raised under the most favorable conditions possible, who remain healthy and escape all the severe illness to which children are subject. He urges especially school physicians to undertake this study.

3. Recovery from Pneumonia in Spite of Leucopenia.—Petroff says that a pneumonia may end favorably, even when a leucopenia is present. This was the case in the patient whose history he reports. Leucocytic reactions take place in persons with leucopenia in the same way as in normal persons, and in pneumonia in such patients there is an increase of the number of white cells found in the blood, with a preponderance of the polynuclear or overripe forms, while the destruction of the white cells is not as rapid as in normal conditions. The blood, in other words, is older and the destruction of white cells is retarded.

4. Typhus Fever in an Infant Five Months Old.—In this case Eminett observed a very severe course, although the child recovered in the end. Cases of typhus are extremely rare in infants under six months of age, and are rare in young children. In Russia, where epidemics of typhus fever have been comparatively frequent, only 0.2 to 0.5 per cent. of all cases occurred in children under one year of age. The case observed by the author occurred in the family of a farmer and was a part of an epidemic involving the farm hands and other inhabitants of a hamlet.

BOSTON MEDICAL AND SURGICAL JOURNAL.

May 11, 1905.

1. Infections of the Respiratory Tract with Influenza Bacilli and Other Organisms, Their Clinical and Pathological Similarity, and Confusion with Tuberculosis (*To be continued*), By FREDERICK T. LORD.
2. Perforated Duodenal and Gastric Ulcers: A Report of Two Cases: Operation: Recovery, By CHARLES L. SCUDDER.
3. Some Suggestions in Regard to the Diagnosis of Seminal Vesiculitis, By HUGH CABOT.
4. Report of a Case of Exstrophy of the Bladder, with a Consideration of Operative Treatment, By HENRY G. SPOONER.

2. Perforating Ulcers.—Scudder summarizes his two cases thus: One case was an ulcer of the stomach. The other case was an ulcer of the duodenum. Both ulcers perforated, causing acute peritonitis. The first patient was operated upon four hours after the initial sign of perforation. The diagnosis of a perforated gastric ulcer was confirmed. The second patient was operated upon forty-eight hours after perforation. It was thought previous to operation that the patient had an appendicitis and a general peritonitis. Both the ulcers were closed by sutures. The peritoneal

cavity in each instance was quickly cleansed by salt flushing and wiping. Cigarette and tube drains were used for a few days only in each case. Both patients recovered. In each case at a subsequent time a posterior gastrojejunostomy was done. The anastomosis was made close to the ligament of Treitz. Both patients recovered from the second operation and are well to-day. The report of the cases is followed by an analysis of their course, and the paper ends with a review of the symptomatology and treatment of duodenal and gastric ulcers.

3. Seminal Vesiculitis.—Cabot contends that the diagnosis of seminal vesiculitis is frequently made on insufficient grounds. He insists that for the termination to be correct there must be a true inflammatory condition. This implies the presence of infiltration and inflammatory exudate. The author studied nineteen cases of the type usually classed as seminal vesiculitis. He found that in only three of the cases was true inflammation of the seminal vesicle at all reasonably certain. The remaining nineteen cases were cases of prostatitis. The author has no intention of disparaging the work done by Fuller, but believes that with some seminal vesiculitis is a hobby.

4. Exstrophy of the Bladder.—Spooner reports the case of a man of twenty-four years who, though suffering from exstrophy of the bladder, was in robust health and managed to live a fairly comfortable life. The author's review of the operative treatment of this condition leads him to formulate the following conclusions: (1) Continence is never obtained by the most successful plastic operation. (2) Implantation of the ureters into the bowel is a difficult operation, and apt to be followed by infection of the kidneys. (3) The operation of Sonnenburg is a simple operation and with less danger than the others and permits the patient to wear a comfortable urinal. (4) Patients can live to old age without any operation.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

May 13, 1905.

1. The Therapeutical Art, By OLIVER T. OSBORNE.
2. The Therapeutical Use of X Rays. Three Years After, By WILLIAM ALLEN PUSEY.
3. A Bacteriological and Clinical Study of a Curative Serum for Typhoid Fever, By WILLIAM ROYAL STOKES and JOHN S. FULTON.
4. Lead Poisoning. A Study of the Gastric Contents in Twelve Cases, By JOSEPH SAILER and JOHN M. SPEESE.
5. Brain Hæmorrhage, By W. A. DICKEY.
6. The Manufacture and Use of Tin Splints. With Some Special Appliances, By ARTHUR T. MANN.
7. The Diagnosis and Treatment of Abdominal Pain, By JOHN B. DEAEVER.
8. Report of the Medical Department of the Universal Exposition, St. Louis, 1904, By LEONIDAS H. LAIDLEY.
9. Immunity. Chapter XV. (*To be continued*).

2. The X Ray.—Pusey's personal experience with the x ray in the treatment of a large variety of affections has been in hypertrichosis, not very

satisfactory; sycosis and tinea, exceedingly satisfactory; acne, a little short of marvelous; rosacea, as in acne; hyperidrosis, of value; inflammatory dermatoses, of much value; lupus erythematosus, disappointing; pruritus, of benefit; pigmented and vascular naevi, of distinct value; keloid and scars, can be cured; lupus vulgaris, of value; tuberculous glands, variable results; tuberculous joints, variable results; abdominal tuberculosis, of apparent value in one case; deep sinuses, no radical relief; blastomycosis, uniformly favorable; actinomycosis, one cure (potassium iodide also used); cutaneous carcinoma, can be used with confidence; epithelioma of lip, to be employed only with extreme caution; senile keratosis and leucoplakia, fairly good results; carcinomata in the neck, of no utility so far as cure is concerned; mixed tumors of parotid, effect indeterminate; recurrent carcinomata of the breast, results at times brilliant; primary carcinomata of breast, treatment should not be undertaken when operation is feasible; sarcomata, react as do carcinomata; pseudoleucæmia and leucæmia, patients improve, but the results are not radical; goitre, results on the whole negative.

3. **A Serum for Typhoid.**—Stokes and Fulton believe they have succeeded in producing a serum for the treatment of typhoid fever which shortens the febrile period of the disease and favorably modifies the daily variations in temperature. Details of their work are given in full.

4. **Lead Poisoning.**—Sailer and Speese conclude: (1) In a series of 12 cases of lead poisoning, or suspected lead poisoning, there was deficiency in the secretion of HCl in 10 of the chronic cases, and no deficiency in 2, one of which was doubtful and the other acute. (2) This deficiency in the secretion of free HCl in the majority of cases is associated with an extreme reduction in the percentage of peptic digestion, and with the presence of lactic acid. (3) It is not justifiable at present to regard it as an indication for treatment, at least not until the effects of the ordinary treatment for achylia gastrica in cases of lead poisoning have been tested.

7. **Abdominal Pain.**—Deaver shows the importance of carefully trying to determine the significance of abdominal pain. If the cause can be removed well and good. If it cannot or if preparations for a suitable operation are under way these anodynes should be resorted to, but not otherwise.

MEDICAL NEWS.

May 13, 1905.

1. **Physiology the Basis of Clinical Medicine.** Suggestions as to Courses in Applied Physiology,

By J. MADISON TAYLOR.

2. **On the Hypodermic Use of Adrenalin Chloride in the Treatment of Asthmatic Attacks,**

By DAVID M. KAPLAN.

3. **Principles Governing the Technics of Röntgen Ray Therapy,**

By ENNION G. WILLIAMS.

4. **Common Causes of Gynecological Disease, with Some Remarks on Prophylaxis,**

By GEORGE GRAY WARD, JR.

5. **Remarks on Treatment of Fulminating Appendicitis,**
By J. M. INGE.
6. **Gonorrhœal Arthritis,** By HENRY W. FRAUENTHAL.
7. **A Case of Sudden Death in a Newly Born Infant Due to Suprarenal Apoplexy,**
By R. E. PICK.

1. **Physiology.**—Taylor holds that there should be special teaching in applied physiology in addition to the systematic course. Unless the student is specifically instructed in applying the principles of life, growth, and functionation to the elucidation of the natural history and phenomena of change and disease, it is impossible for him to grasp the principles of general pathology or to form sound concepts of therapeutical measures. The paper concludes with a number of letters written to the author by the leading teachers of physiology in the United States concerning this subject. With very few exceptions they favor the author's position.

3. **The X Ray.**—Williams asserts that the great variations in the results obtained by those using the x ray are due more to personal equation than to difference in apparatus. He gives briefly his own views regarding the most effective ways of applying the Röntgen ray in different conditions.

4. **Gynecological Diseases.**—Ward asserts that one eighth of gynecological diseases are due to gonorrhœa and that two thirds are due to pregnancy and its consequences. A large proportion of the cases consequent on parturition or abortion could be avoided if all women were properly attended. It is therefore "up to" the general practitioner to improve the present lamentable condition of affairs.

5. **Fulminating Appendicitis.**—Inge gives the following concise advice: "If we have a case developing rapidly too late for an early operation, too early for a late operation, the mass or tumor, due to adhesions, easily felt by palpation, we adopt the course given by Ochsner to localize the infection. In addition, drain by a small stab wound, through abdominal muscles, transversalis fascia, and peritonæum to the mass of adhesions. If pus escapes, use only a narrow strip of rubber tissue as suggested by Robert Morris, not wider than a pencil; if no pus, only serum, a small, loosely rolled gauze wick surrounded by rubber tissue, not larger than a pencil. If there is no suppurative condition, yet pus may escape in a few hours. Whether pus or only serum escapes in small quantity at first, the capillarity is such that the flow of the infected material will certainly and promptly start in the direction of the drain and escape externally. Tissue pressure will force it along the line of least resistance, more especially so in cases of appendicitis where the muscles contract and are constantly rigid, much more so than in cases of salpingitis and oophoritis and other intraabdominal inflammations; such drains will draw quarts of fluids from the abdominal cavity by capillarity."

6. **Gonorrhœal Arthritis.**—Frauenthal asserts his belief that if the same zeal was displayed in seeking for gonococci as a cause for arthritis as

there is in looking for uric acid and urates, it is possible that more cases of gonorrhoeal arthritis would be found. The treatment of specific arthritis recommended is thus summarized: In the acute stage iodine should be painted over the joint, ice bags applied about the joint, a fixation splint to hold the joint immovable, with sufficient morphine internally to appease the pain. Cautery over the joint relieves the pain; also the high frequency current. As a last resort, arthrotomy may be employed. In the subacute and chronic stage the use of blue ointment, Credé ointment and liquid iodi comp., combined with dry heat and galvanic electricity, are of great value. All joints should be put at rest in plaster, as this makes the most easily applied and most perfectly fitting splint for all joints except the hip, which requires a Thomas or Sayre traction splint. In the phlegmonous joint, extension and counter-extension should be used. Urotropin, salol, carbonate of guaiacol, carbonate of creosote, and quinine are underestimated in their value for destroying gonococci found in the interior of the body.

AMERICAN MEDICINE.

May 13, 1905.

1. Surgical Intervention in Cases of General Peritonitis from Typhoid Fever and Acute Gonococcus Infection, By JOSEPH PRICE.
2. Diphtheria Antitoxine in Cerebrospinal Meningitis, By ARTHUR J. WOLFE.
3. Gallstone Obstruction of the Bowel; Report of a Case; Removal of One Stone from the Bowel and a Second from the Gall Bladder: Recovery, By ALFRED C. WOOD.
4. The Alleged Destruction of Red Blood Corpuscles in the Spleen, By EDWARD T. WILLIAMS.
5. Pancreatic Cyst: Report of Case, By M. J. KARPELES.
6. The McGraw Elastic Ligature for Gastroenterostomy Secondary to Murphy Button: Operation with Description of Technics, By R. J. CHRISTIE, JR.
7. Gunshot Wounds and Their Treatment, By JOHN R. COOK.

1. **Peritonitis.**—Price urges early diagnosis, early intervention, more thorough cleaning of the soiled peritoneal cavity. He favors drainage, irrigations with plain sterile water (not hot saline solution), and the curetting or wiping of dirty points. In typhoid resection of the gut is not justifiable. If the gut is in very bad condition close perforations with interrupted sutures and anchor the gut to the wound in the abdominal wall. If a fistula forms it will usually close spontaneously.

2. **Diphtheria Antitoxine in Meningitis.**—Wolfe reports the observations and experiments which led him to suggest the use of diphtheria antitoxine in the treatment of epidemic cerebrospinal meningitis. He believes that there is an antagonism between the Klebs-Löffler bacillus and the meningococcus, that the Klebs-Löffler bacillus is precipitated and agglutinated by the meningococcus when rich cultures of both are mixed; that the diphtheria antitoxine in proper proportion inhibits the growth of the meningococcus. The author finds that the meningococcus assumes a varying morphology according to the

media in which it is grown, and that the positive or negative reaction to Gram's stain is not absolute for the diagnosis of the meningococcus. Clinically the author presents no evidence to show that diphtheria antitoxine will influence the course of epidemic cerebrospinal meningitis.

3. **Gallstone Obstruction of the Bowel.**—Wood reports his own case and reviews the history, symptomatology, and treatment of gallstone obstruction of the bowel. The paper ends with abstracts of twenty-one similar cases reported since the appearance of Gibson's paper on the subject in 1900.

7. **Gunshot Wounds.**—Cook is very positive in his belief that all gunshot wounds should be drained. This is specially true in the case of wounds of the viscera. If drainage was always employed the author is certain that the mortality from this class of injury would be greatly reduced.

MEDICAL RECORD.

May 13, 1905.

1. The Tuberculosis Situation in Penal Institutions, with Especial Reference to the State Prisons at Sing Sing, N. Y., and Columbus, Ohio, By S. A. KNOPF.
2. Dermatitis Seborrhoica and Its Relations to Alopecia and Other Conditions, By L. DUNCAN BULKLEY.
3. Prostatectomy, By REGINALD HARRISON.
4. The Importance of Early Recognition of Suppurative Ear Disease, By ALICE G. BRYANT.
5. The Treatment of Epidemic Cerebrospinal Meningitis with Injections (Chiefly Intraspinal) of Diphtheria Antitoxine, By GEORGE L. PEABODY.
6. A Case of Long Standing Major Hysteria Characterized by a Paroxysmal and Fixed Pain, Mental Depression, Confusion, Delirium with Delusions, and Hallucinations Terminating in Sudden Recovery, By THEODORE DILLER.
7. A Case of Menstrual Urticaria, By D. J. M. MILLER.

1. **Tuberculosis.**—Knopf describes a number of the most unsanitary features existing at Sing Sing and at Columbus, and the most easily applicable remedies. So far as the tuberculosis problem is concerned the following suggestions are made: (1) The State Prisons should be rebuilt and their location changed to some high and dry locality. (2) Tuberculous prisoners should be sent to penal farms. (3) Convicts should be examined on admission to both city and State jails. (4) Examinations should be repeated at definite intervals, say, every three months. (5) Sanitary measures should be rigorously enforced. We cannot give in detail all that is implied in this last recommendation. That the problem of tuberculosis is a very real one in prison management must be conceded when it is remembered that the death rate from tuberculosis averages about fifty per cent. of the total death rate.

2. **Dermatitis Seborrhoica.**—Bulkley defines dermatitis seborrhoica as a chronic, more or less inflammatory affection of the skin, probably of microbic origin, exhibiting varying degrees of scalliness, generally of a greasy character, on normally colored or moderately congested skin, with

a tendency to extend (generally from the head downwards) by sharply defined, commonly circular areas. It is frequently accompanied with itching, which, however, is not as severe as in eczema. Most observers agree that the eruption is primarily one of the scalp, causing one of the forms of dandruff, where it may remain confined for years, and suddenly develop elsewhere, as a scaly eruption, or with more or less inflammatory symptoms. This affection is most commonly confounded with tinea, pityriasis rosea, psoriasis, eczema, and at times syphilis. It constitutes about one tenth of all the skin lesions met in private practice. It is very amenable to treatment. Resorcin and sulphur lotions give the best results.

3. **Prostatectomy.**—Harrison favors the suprapubic route for performing prostatectomy. The mortality by either of the two routes, perineal and suprapubic, is about the same. The advantage of the latter method lies in the after results and in the facilities it affords for detecting calculi when present.

5. **Diphtheria Antitoxine in Meningitis.**—Peabody gives the results obtained by himself and Jacobi at Roosevelt with diphtheria antitoxine in the treatment of twenty-two cases of cerebrospinal meningitis. In their hands neither good nor bad resulted from the experiment. Some of the cases are still in hospital and the mortality is to date fifty per cent.

7. **Menstrual Urticaria.**—Miller reports the case of a girl of 15 years, who began to menstruate at the age of 12 years. The periods were, at first, irregular, but for the last two years have recurred regularly every four weeks, lasting from three to four days each time. With the establishment of regularity the attacks of urticaria began. They make their appearance seven or eight days, and cease from two to three days, before each period. Occasionally the urticaria persists until the flow begins, rarely during the first day or two of its course. During the intervals between the periods the patient is quite free from attacks. That the skin affection is dependent upon the menstrual flow is shown by the fact that, owing to a change of residence from England to this country, some eight months ago, the patient missed two periods, and that during these two months she was quite free from urticaria.

13. An Osteoma of the Frontal Sinus, By HASTINGS.

1. **Studies on the Pathology and Ætiology of Obstructive Hypertrophy and Atrophy of the Prostate Gland.**—Pilcher, from a careful investigation of many specimens relating to this subject reaches the following conclusions: 1. Pathologically there are three types of prostates causing urinary obstruction: (a) the large soft type, (b) the hard, small contracted type, (c) the mixed type. 2. Infection does not influence the variety of the pathological change. 3. The contracted form of prostate is not a secondary stage of the large soft type of hypertrophied prostate, but is distinct from it. 4. In many cases of hypertrophy of the prostate there is present a true muscular hypertrophy. 5. In some of the atrophic cases the glandular elements are relatively diminished and the muscular elements relatively increased. 6. Gonorrhœa is not an important ætiological factor in the production of this disease, and there is no necessity for assuming that it is. 7. The theory of obstruction to the ducts causing passive dilatation of the glandular elements, as advanced by Ciechanowski, and Crandon does not satisfactorily explain the pathological findings. 8. Hypertrophy of the prostate results from glandular overgrowth, influenced by the degenerative changes of old age, and other agencies which tend to cause the development of fibrous connective tissue in an actively functioning gland.

2. **Has the Catheter a Place in the Treatment of Chronic Prostatic Hypertrophy?**—Thorndike answers this question by saying that the catheter has such a place. While it is true that radical operations upon the prostate are pushing the catheter and other palliative measures aside, there are many patients who are unfit to endure the shock of such radical procedures and others who are better off after palliative measures. These cases include old and infirm men in whom prostatic symptoms have developed slowly, and who may be made comfortable by the proper daily use of the catheter. When palliation ceases to be possible operation should be undertaken in spite of its risks. In another class the patients are relatively young, but the bladder, though clean, is overdistended and atonic. Three catheterizations in the twenty-four hours keep them free from all discomfort. In yet another class the quantity of residual urine is small, and the bladder clean. The

annoying symptoms may be palliated and an occasional visit to the surgeon may be all that is required. This still leaves a large number of patients in whom the condition and surroundings are such that only the radical operation will place them in a condition of safety and comfort.

3. Prostatism Without Enlargement of the Prostate.—Chetwood analyzes thirty-six cases in which contracture of the neck of the bladder was found to be a cause of vesical obstruction. He found in these cases that a safe and sure relief could be obtained by means of galvanoprostato-tomy through a perineal opening. This condition produced the symptoms of prostatism, though the prostate was not enlarged.

4. Anatomical Points in Prostatectomy.—Watson shows by photographs of suitable specimens: 1. The completeness of the tumor formation in each of the three lobes, and their separation from the fibrous sheath which incloses the gland; 2, the thickness of the outer sheath; 3, the space between the surface of the gland and the inner aspect of the outer sheath. Enuclations should be made in this space; 4, the level of the lower border of the urethral aspect of each lateral lobe is above that of the floor of the prostatic urethra and above the level of the ejaculatory ducts. An operation which does not injure the floor of the prostatic urethra will not injure the ducts; 5, the tumor formation of the middle lobe is outside the urethra, and intravesical. It is also outside the sphere of the ducts which, therefore, need not be injured in its removal. The author refers to the services of Gouley in insisting, for many years, upon the desirability of radical procedures upon the prostate. He also alludes to the fact that he has been an advocate of the same procedure for seventeen years, asserting that the mortality from catheter treatment was greater than from prostatectomy. He believed the perineal operation to be the one of choice, but that in a minority of cases the suprapubic route must be accepted.

6. Suprapubic Prostatectomy.—Lilienthal, after an experience of thirty-one cases at the Mount Sinai Hospital, expresses his belief that this is the safest and most thorough of all the operations for the relief of prostatic obstruction. It is radical, no important vessels or nerves are cut, the urethra is not injured, the rectum is less rarely wounded than by the perineal method; palpation and inspection of the interior of the bladder are easy and accurate and precedent cystoscopy is not necessary. There is very little shock, and the urethra being uninjured, the subsequent passage of sounds is unnecessary. Drainage is accomplished by siphonage. The operation may be performed under local anesthesia. The operation may be performed in two stages which is of great value in hæmorrhage, uræmia, or sepsis of the bladder when catheterization is difficult, painful, or dangerous. It may be performed more rapidly than any other method. It is a very simple operation, and is rarely followed by impotence.

8. Conservative Perineal Prostatectomy.—Young has operated upon 200 hypertrophied prostates, and believes that for most cases the perineal method is the safest, surest, and quickest in producing a cure. The Bottini method is the simplest and quickest for a limited number of cases, which may be determined by the cystoscope, but it is not so safe nor so sure of relieving the obstruction as the perineal enucleation. The suprapubic route may be used for large intravesical lobes. A careful preliminary cystoscopy should always be made.

5. Practical Gynæcology, By SELLMAN.

1. Value of the X Rays in the Treatment of Fractures.—Campbell thinks the diagnostic value of the x ray, compared with its therapeutical value, is unquestioned. Cases of fracture may be divided, in this connection into three classes: (1) those in which the condition are so apparent and palpable that an x ray picture would be deemed unnecessary; (2) those in which an incomplete diagnosis is made, subsequent symptoms showing that the real lesion was not appreciated; (3) those which are seen immediately after the injury and in which, by means of the x ray, exact diagnosis, reposition, and retention may be accomplished. The author thinks this means should be utilized as a routine procedure in all cases, the radiograph being filed with the history of the case for convenient reference and for the protection of the physician.

1, 2, 3, 4. **Cancer.**—Beatson puts forward as the most likely explanation of carcinoma what he terms the "germinal theory." It assumes the existence of a general tissue secretion that cannot be absolutely proved, but in favor of which there is a fair amount of reasonable and confirmatory evidence. With such a procreative fluid in the body, in the event of the testes or ovaries through functional decay or disease being unable to deal with it, and the fat of the body having no special capacity for storing it, it is possible that tissues or organs that have retrograded physiologically, and, by losing their differentiation, have reverted to a more primitive type, should under these conditions take upon themselves the function of secreting it when they would, of course, do so in the cellular form followed by the normal reproductive tissue. This is a return to some extent to the old "spermatic" theory of cancer, but it does not assume a conversion of the normal tissue of the part into tumor tissue—on the contrary, the masses of the tumor cells are not looked on as a tissue at all, but as cells thrown off by altered somatic cells in the elaboration of a special secretion. In carcinoma we have a tissue secretion to deal with, in relation to which the fat of the body probably acts as a middleman just as lymph does in ordinary nutrition. This being true we should not be too pessimistic as regards the successful treatment of the disease.

Cleveland and Day report the case of a married woman, aged 40 years, who was suffering from cancer of the uterus. The growth was so extensive and adherent to adjacent parts, that removal by operation was deemed inadvisable. As a forlorn hope the x rays were tried, a moderately high tube excited by a mica plate static machine being used, and the rays applied directly over the pelvis for fifteen minutes at a time three times a week, the tube being about six inches distant from the skin of the abdominal wall. At first there was little change, but in two months she began to improve, and five months later vaginal examination showed the tumor to have disappeared and the uterus to be freely movable. At one time the cessation of treatment was followed by a return of the symptoms.

Cheattle has studied the points of incidence in which the cancer process begins in the skin, confining his example of cancer to rodent ulcer. He finds that the points of incidence of primary cancer occur at points at which the nerves become cutaneous, corresponding with the points of incidence of the so called neurotrophic diseases—leucoderma and scleroderma. The points of incidence in the latter diseases correspond also to those points at which nerves become cutaneous. The author's opinion is that the incidence of cancer may be due to the direct or indirect nervous influence of the area in which it occurs. The nervous influence which affects its incidence is probably either peripheral, or a peripheral modification of central influence and not only segmental.

Drage reports the results obtained by him in the

treatment of cancer by the subcutaneous injection of a ten per cent. solution of sodium cinnamate, or of a twenty-two per cent. solution of sodium orthocoumarate. The dose of the former is thirty minims once or twice a week, of the latter twenty-five minims at the same interval. In two cases of cancer of the pharynx and larynx, relief from pain and distressing symptoms were experienced, and the discharges were free from fætor. In a case of lymphatic recurrence and in another of cancer of the breast, the tumors disappeared entirely. Patients when they die, do so from simple exhaustion and not from the old horrors of the disease. Early diagnosis is of supreme importance.

7. **Torsion of the Spermatic Cord.**—Dowden states that torsion of the spermatic cord is more frequent than is generally supposed. There are two varieties: (1) Characterized by one sudden and acute attack; and (2) more or less frequent recurrence with or without the eventual onset of an acute degree of torsion. The main predisposing factor is the abnormal manner in which the testicle, suspended by the cord, hangs free in the tunica vaginalis. The exciting causes are indefinite—strain, walking, crossing the legs, coughing, defecation, etc., are among those assigned by the patients. In many instances the attacks come on at night. There is sudden onset of pain in the testicle, sickening in character and spreading upwards over the hypogastric region. Vomiting occurs early, and with it signs of collapse. The testicle is tender and in the course of a few hours swelling occurs. Prostration is complete till relief comes in the course of a few hours; the severe symptoms suddenly moderate and the local swelling disappears in the course of a day. Such attacks may come on at intervals of weeks or months. The condition is most likely to be mistaken for epididymo-orchitis: for there is pain, swelling, and extreme tenderness—but there is no urethral discharge, and no history of gonorrhœa, mumps, or traumatism. After swelling has occurred strangulated hernia may be simulated—this is especially true in undescended testicle. The rotation is usually from without inward. A severe attack may be followed by atrophy—and in the recurrent form, if severe and persistent, a certain amount of atrophy usually follows. Treatment consists at first in an attempt to untwist the cord, care being taken to avoid too much force. Detorsion may be a failure, when an operation must be performed to remedy the condition and fix the testicle. The author reports five cases in which such an operation was successfully performed.

8. **Regeneration of Nerves.**—Kilvington summarizes his observations as follows: 1. It is possible to functionate two opposing groups of muscles by a single nerve, which previously supplied one group only; it is possible to innervate fairly completely muscles with a much smaller number of motor horn cells than usually bring about this effect. 2. When the central end of one nerve is joined to the peripheral ends of two nerves there are many more fibres in the peripheral nerves than

in the central nerves, so that the nerve fibres in the proximal trunk divide on going to the distal trunks. 3. In some cases at least some of the branches from one nerve fibre go to supply one set and others the opposing set of muscles. This may prevent very delicate movement being restored. 4. After this form of suturing the arrangement of the nerve fasciculi in the peripheral nerves is considerably altered.

By D. McCAY and E. O. THURSTON.
9. Two Cases of Tetanus Treated by Antitetanic Serum,
By R. A. STONEY.

1. **Nutrition.**—Allchin, in the first of his Lumleian lectures, states that in the discussion of nutrition and malnutrition there are two factors to be considered at the onset—the bioplasm on one hand and the food or nutriment on the other. He considers in detail the proximate principles of the bioplasm: (a) proteids, free, and combined, the former including the albumens, albumoses, globulins, and peptones, the latter hæmoglobin, glycoproteids, and nucleoproteids; (b) the fats; (c) the carbohydrates; (d) the various inorganic salts; and (e) water. This living matter is of unknown and perhaps unknowable exact composition, of the chemical nature of which we have any conception from its derivatives only. The food corresponds in great measure to the same derived substances. He next presents in summary an account of the successive changes undergone by the ingesta from their intake to their assimilation by the bioplasm.

2. **Cerebrospinal Meningitis.**—Ormerod reports two cases of cerebrospinal meningitis—one tuberculous, and the other of uncertain origin. He calls attention to the following points: 1. When meningitis occurs as a terminal event in the course of some severe primary disease, it may present no really distinctive symptoms; they may be so merged in those of the original disease that the meningitis is "latent" and only discovered post mortem. 2. In severe cases of meningitis coma may be an early symptom and so pronounced as to mask nearly all the others. 3. Since

the disease is an acute affection it presents the common symptoms of acute infectious disease; and as there is extensive lesion of the nerve centres there are also general symptoms of nervous disease. Under these heads may be reckoned fever, vomiting, headache, pain and tenderness, and optic neuritis. The pain in the head and back is so frequent that it is almost distinctive. 4. Still more characteristic signs are: (a) retraction of the head and opisthotonos, indicating that the base of the brain or the upper part of the cord is specially involved; yet in acute disease, especially in pneumonia, retraction of the head may occur and pass off completely in a day or so; (b) Kernig's sign, resistance to extension of the legs when the thighs are semiflexed on the abdomen; this is probably due to the pain caused by the tension which is put upon the inflamed sacral nerve roots. A similar phenomenon is often observed in sciatica; (c) lumbar puncture, which is an important aid to diagnosis. A long fine trocar and cannula are introduced into the third lumbar interspace; this is relatively easy in children, but harder in adults. In the normal subject the fluid is clear, but in most cases of meningitis it is turbid or even purulent.

4. **Hydrochloric Acid in the Gastric Juice.**—Moore, Alexander, Kelly, and Roaf have investigated the secretion of hydrochloric acid in the stomachs of patients suffering from malignant disease of other organs than the stomach. They find that the absence of free hydrochloric acid in cancer of the stomach is not due to local action in that organ, for hydrochloric acid is absent or reduced greatly in amount whatever may be the situation in the body of the malignant growth. Using the various tests for the various forms of acidity they obtained the following results: 1. The total acidity in malignant disease, wherever situated, is very low. Of 17 cases, only one showed the normal total acidity of 0.28 per cent. 2. There was entire absence of acidity in over 50 per cent. of the cases—9 out of 16. 3. In 11 out of 17 cases there was an entire absence of free hydrochloric acid—and in the remaining six there was only the merest trace. 4. 5. Certain test methods gave relatively high acidity figures because of the presence of inorganic acid combined with an organic base. 6. The methyl-acetate inversion method shows clearly what small traces of effective acid are present as compared with the normal cases. 7. After removal of the growth, there is not a re-appearance of acid. This tends to show that there is a persistence of those conditions in the body tending to favor the reformation of new growths.

9. **Tetanus.**—Stoney reports two cases of tetanus treated with antitetanic serum, which presented a marked contrast to each other. In both the incubation period was long, in the first case 17 days and in the second case probably 18 days. In both the temperature was normal on the first appearance of the symptoms, in the second case it remained normal throughout the course of the disease; but in the first case after a preliminary fall it rose rapidly through 102° F. in twenty hours. In both cases the treatment was the same

—i. e., injection of serum and the administration of large doses of bromide of sodium and chloral by the rectum. In the one case death occurred within sixty hours of the onset of the first symptoms, whereas the second patient recovered. In the first case the spasms were frequent and severe, while in the second only one was observed. The result was due to the degree of infection and was not materially influenced by the treatment.

GLASGOW MEDICAL JOURNAL

April, 1905.

1. Some Cases of Uterine Myoma, with Remarks on the Indications for Operation, By RUSSELL.
2. Movable Displacements of the Kidney, By NEWMAN.
3. Pyelophilitis in Relation to Carcinoma and Foreign Bodies, By RUTHERFORD.

1. **Uterine Myoma, with Remarks on Indications for Operation.**—Russell speaks of two classes of operations: 1, Those in which the checking of the growth of the tumor is the object, or possibly its disappearance, by lessening its nutrition. This form of operation is unreliable, whether it consists in tying the ovarian arteries and removing the appendages, or in ligating the uterine arteries per vaginam or in tying them by abdominal section or in ligating the entire broad ligament. Only interstitial fibroids are likely to be influenced by such an operation, but there are cases in which this is the only operation that is available; 2, those in which the removal of the tumor alone, or the tumor and uterus, by either the vaginal or abdominal route, is the object of the operation. The author prefers the supravaginal form of hysterectomy, although recently he has followed the plan of Bland Sutton and excises the cervix as well as the uterus and tumor. An operation may be required for other indications than hæmorrhage, and if it is delayed there may occur not only growth and degeneration of the tumor, but interference with neighboring organs, and a distinct myomatous cachexia, with accompanying cardiac hypertrophy, blood changes, and physical weakness. These factors add to the risk of the operation and lessen the chances of recovery.

2. **Movable Displacements of the Kidney.**—Newman gives the following list of advantages which nephrorrhaphy offers compared with nephrectomy: 1, In nephrorrhaphy the organ is not removed, secreting tissue is therefore not diminished, and there is no danger of removing the only organ the patient has; 2, the mortality in nephrectomy is thirty per cent., the mortality in nephrorrhaphy is a little more than one per cent.; 3, nephrorrhaphy may be performed when both kidneys are movable or when one is diseased; 4, in stitching the kidney to abdominal wall the peritonæum is not opened as in the anterior operation for nephrocetomy, when the peritonæum is incised at least twice; 5, nephrectomy is only permissible when nephrorrhaphy has failed, where the patient's life is still seriously threatened, and where the movable kidney is diseased, and the fixed kidney is healthy.

Letters to the Editor.

INFECTION THROUGH THE TONSILS.

1801 PINE STREET,
PHILADELPHIA, May 2, 1905.

To the Editor,

Sir: In connection with Dr. Anderson's excellent paper on the very interesting subject of infection through the tonsils, in your issue of April 29, 1905, will you permit me to direct attention to a striking instance of infection through this portal reported by me in the *Archives of Pediatrics*, for June, 1904? The patient, a girl of ten years, who had suffered repeatedly from amygdalitis, was again attacked during a house epidemic of the disease, and immediately thereafter had polyarthritis, purpura, abdominal colic, intestinal hæmorrhage, and severe hæmorrhagic nephritis, the latter persisting for ten or eleven weeks, but ending in complete recovery.

This winter an almost identical case has been under my care, with the exception that the attack did not follow so closely upon an acute amygdalitis, the relation to the tonsillar inflammation being limited to a history of repeated attacks of that disease. This patient, also a girl, aged thirteen years, was seized early in December, 1904, with febrile polyarthritis, together with a maculopapular purpuric rash on the extensor surfaces of the upper and lower limbs, especially about the joints, and upon the buttocks. There was no pruritus. In addition, there were attacks of severe abdominal pain, with vomiting of blood, and the passage of bloody and mucous stools. These symptoms lasted for ten or eleven weeks. From the first the urine had been bloody, and contained much albumin and many casts, hyaline, granular, and blood, as well as numerous red and white blood cells. When she was first seen, a month after the onset, the face was swollen and the eyelids were puffy; but there was no œdema of the lower limbs. The nephritis persisted until the patient passed from under observation, i. e., sixteen weeks from the beginning at the attack. The urine was at this time that of chronic nephritis, viz.: loaded with albumin; sp. gr., 1.004 to 1.008; hyaline and granular casts. Blood cultures were negative. The temperature varied. At the onset there seemed to have been considerable fever, but later the temperature was usually below normal, although it occasionally rose to 100° F. and over.

How these cases should be classified will not be discussed here. They belong to that interesting class of cases which Osler has brought together under the heading of The Visceral Manifestations of the Erythema Group of Skin Diseases. In some respects they resemble the so called Henoch's purpura. My purpose in reporting them now is to emphasize the importance of recognizing the tonsils as a port of entry for infective processes. That the poison which induced the severe symptoms in the first case gained entry to the system through this gateway seems more than probable; it seems almost impossible to interpret the rapidity with which the general symptoms followed the throat affection by any other hypothesis. In the second case the relation, perhaps, is not so clear. There was no history of an acute amygdalitis immediately pre-

ceding the arthritis and other symptoms, but the patient was subject to amygdalitis, and the tonsils were enlarged and scarred, a certain evidence of repeated inflammatory attacks. In addition to the two cases just mentioned, I recall still another instance of apparent infection through the tonsils. A lady of thirty-five years, who had been subject to acute amygdalitis from early childhood, was attacked severely with the same affection (temperature, 105° F.; marked prostration; extensive exudate, which proved to be due to the streptococcus only). After five or six days the throat symptoms abated, but a week later subacute polyarthritis occurred, from which the lady has suffered repeatedly ever since, a period of eight years.

Surely with such histories we should regard amygdalitis with more apprehension than is usual. An affection capable of inducing such serious conditions as endocarditis, nephritis, rheumatic polyarthritis, and even tuberculosis (Koplik) is not to be considered lightly. Individuals subject to amygdalitis should be guarded as much as possible from repeated attacks, and when attacked, should receive prompt local and general treatment, being kept at rest (in bed) until the acute symptoms, especially the fever, have subsided. D. J. M. MILLER.

HEREDITY.

ELEVENTH AND PINE STREETS,
PHILADELPHIA, April 13, 1905.

To the Editor,

Sir: In my editorial on Pathological Heredity, published in your journal for March 25, 1905, the remark concerning the effect of parental toxic conditions on the sperm, germ, cells, and impregnated ovum has become the subject of inquiries from various sources. Instead of answering individually, I prefer to ask you for a small space in the columns of your journal, as it may be of interest to your readers in general.

Féré has shown experimentally the influence of vapor of alcohol on incubating eggs during the pre-embryonic stage. The results of these interesting experiments were published in *Comptes rendus de la Société de biologie*, vol. lii, pp. 231, 471, 601, 681, and 790. In the *Biologisches Centralblatt* for 1903, p. 448, Ziegler showed that alcohol injured and retarded the development of the impregnated ovum. Magnan and others have found in the testicles of the dog fatty degeneration with lowered mobility of the spermatozooids.

ALFRED GORDON.

SUPRARENAL EXTRACT IN SCARLET FEVER.

3508 FIFTH AVENUE.
PITTSBURGH, PA., April 18, 1905.

To the Editor,

Sir: I wish to call your attention to a remedy that I have been using in the treatment of scarlet fever for the last five years, with good results. I have treated in that time fifty cases without a fatal result.

The remedy I speak of is a spray of suprarenal capsule extract on the tonsils every hour for the first forty-eight hours, with lessening intervals

thereafter, according to the urgency of the case, and with the administration internally of liquor ammonii acetatis and infusion of buchu freely, the temperature being kept down by tepid baths. The results of this treatment certainly have been remarkable, the temperature becoming normal in from twenty-four to forty-eight hours. In regard to the bacteriological effect of this remedy, at present I am not prepared to give accurate results. I have asked our city physician, Dr. Booth, to investigate these effects and report later. Relative to the strength of the remedy, I use ten grains of suprarenal extract to the ounce of water. I should like to say that in the use of this remedy I have had not one case of enlarged glands in the neck, nor, where the glands have been enlarged before the case was in hand, have I observed any other than perfect resolution.

MALCOLM W. EVERSON.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, March 2, 1905.

The President, Dr. RICHARD C. NORRIS, in the chair.

The Induction of Labor.—(Concluded from page 985.)—Dr. O. HOPKINSON, JR., considered all methods of interfering with pregnancy dangerous. The term "accouchement forcé" was unfortunate, as it implied force, which was not necessarily employed. The slow method was uncertain and sometimes too slow. The choice of method should be determined after a careful study of the case, as every case was a law unto itself. He preferred accouchement forcé in all cases where the cervix had been previously dilated. He used the Goodell dilators to the full extent and then the Harris or Edgar method, and delivered by version or forceps or allowed a spontaneous termination, as the occasion demanded. If there was no need of haste, he preferred the bougie or packing with gauze. Both these methods were uncertain, and if the patient showed signs of fever or a rapid pulse, he terminated labor by accouchement forcé. He had never used the de Ribes bag.

Dr. STRICKER COLES believed there were many cases best treated by the induction of labor. In the cases where the child would be too large for the pelvis if pregnancy was allowed to go to term, the fitting of the child's head to the mother's pelvis was the best index as to the time for the induction of labor. If this showed that labor should be induced before the thirty-second week, it would be better to consider some other method of treatment. While the bougie had given good results in a large number of cases, it should be removed when labor pains become strong and regular, for when it was allowed to remain there was danger of premature rupture of the membranes. This accident had not occurred except in cases where the bougie was left in too long. When the membranes had not ruptured, labor should be allowed to proceed normally, and with

as little interference with Nature as possible. If the membranes ruptured prematurely, then he would insert the bag exhibited by Dr. Norris, which was large enough to give sufficient dilatation with but slight lacerations to the cervix or pelvic floor.

The Bossi dilator must be used with care in completing the dilatation, as there was more danger of causing lacerations at that time. When obliteration of the cervix had not taken place, the Bossi dilator was a dangerous instrument if used to dilate rapidly, and under no circumstances should the cervix be dilated in less than half an hour. He thought the operation of induction of labor was useful and would be successful if the cases were carefully studied and scientifically treated.

Dr. NICHOLSON said, in regard to the aetiology of eclampsia, that in the majority of cases structural changes were found in the kidneys and liver; they might, however, be only microscopical. There was some poison circulating in the mother's system. He failed to see what use there was in doing anything approaching accouchement forcé or any rapid method of delivery in a case of eclampsia. The woman was depressed by the toxins, and the question of a few hours would not make any difference in her life. The changing of a case of eclampsia from the gestational to the puerperal period did not cure the case. While it was true that statistics showed that a woman who did not become eclamptic until after her delivery, was in very much less danger than if convulsed before delivery, nevertheless, there was a distinct mortality in this period, and the mere fact of rapid delivery did not put a gestational case into the puerperal class. Therefore he did not see any reason for the rapid delivery in eclampsia. He believed the slow method was the method of value.

Dr. RICHARD C. NORRIS remarked that he would not like the members to understand that the method he had described was the one he would use under all circumstances. He thought the indication for the induction of labor and the condition of the patient determined largely the method that should be used. For a case with no necessity for a short labor, if the bougie failed, he dilated the cervix mechanically and followed with dilatation by the bag. The method described had enabled him to terminate labor in eight and a half hours, and that was sufficiently rapid for the induction of labor for all the complications he encountered. In cases of heart disease, eclampsia, or placenta prævia, where he thought it to be the best interest of the patient to be delivered rapidly, he used this method in preference to the employment of the Bossi dilator or vaginal hysterectomy. It was a relatively rapid method for the termination of pregnancy, and when, in the obstetrician's judgment, eight or ten hours was sufficiently rapid, it was the method of choice. He could not recall a case where a more rapid delivery had seemed to be necessary.

Dr. HIRST usually employed this method himself, and thought that in selected cases it was going to be a decided addition in the power to ter-

minate pregnancy. In one instance he had been called to a distance from his home and could not return until the woman was delivered. He carried out this plan, and between the time of dinner and dessert the dilatation was sufficient to accomplish delivery. He thought that if the case were near home he would take his chances with the bougies.

Book Notices.

Manual of Antenatal Pathology and Hygiene; the Embryo. By J. W. BALLANTYNE, M. D., F. R. C. P. E., F. R. S., Edin., Lecturer on Midwifery and Gynæcology, Medical College for Women, and Surgeons' Hall, Edinburgh, etc. Edinburgh: William Green & Sons, 1904. 1p. xix+47. (21s.)

Dr. Ballantyne's work has become so well known that the appearance of a new book by him will be greeted with interest. In a former volume the author dealt with the physiology of the fœtus and the deviations from the normal. In the present work he takes up the pathology of the embryo and has given us *in extenso* a work on teratology which embraces not only a great amount of his own labor, but also the newer views as to monsters, their development and aetiology.

The author takes up the chronology of the embryonic life first, carrying it through the sixth week after impregnation and continuing the consideration of its physiology and pathology as outlined in his former volume. He points out correctly that a proper understanding and interpretation of the facts he presents can only be appreciated if embryology is previously studied; for many of his deductions are based upon observation of deviations from the normal development.

After considering in detail the theories as to teratogenesis—mental impressions, traumatism, fetal diseases—Ballantyne goes on to a classification of teratology historically considered. This is followed by a description in detail of the various types of monsters and deviations. Illustrations of the various forms are given, with dissections in many instances, and mostly from original sources.

Ballantyne does not believe that "definite impressions upon a pregnant woman's mind can ever cause a defect in the fœtus closely resembling the thing producing the impression," but he is frank to affirm that the mother's mental attitude during pregnancy may have an effect upon her unborn child in the way of premature labor or retarded growth or development. These conclusions are reached after a most careful consideration of the evidence on both sides of the question, not only of the literature of recent times, but of that of ancient profane and scriptural writings as well.

The practical solution offered by the author to reduce the number of the births of monsters and of those pathologically tainted, must be regarded as somewhat chimerical. He urges those who are themselves "endowed with the sad legacy of family ill health" not to reproduce; but if they do, to keep themselves free from every possible taint, especially

alcoholism. "It is a family matter, in this kind of treatment," says the author, "the cleanness of life and the control of the indulgence of morbid cravings for narcotics and stimulants of the parents does much, but it may be insufficient, to effect a cure." Several generations may be required to blot out a serious deviation from the normal. The theory is undoubtedly correct, but it is not new, and it applies equally well to those of normal birth and form and habit. However, there is no question that Ballantyne has done superb pioneer work in reviewing anew the complex data of teratogenesis and its forms, and his work, now that it is completed, must, perforce, rank as one of tremendous value to the scientist, to the embryologist, and to the physician to whom the uplifting of the race is dear.

Burdett's Hospitals and Charities, 1905. Being the Year Book of Philanthropy and the Hospital Annual. By Sir HENRY BURDETT, K. C. B., etc. London: The Scientific Press. Pp. 966.

This volume well sustains the reputation of its predecessors for comprehensiveness and accuracy of information concerning the hospitals, asylums, dispensaries, sanatoria, etc., of the English-speaking world. It would be hard to think of a point in hospital administration on which it does not give all the data obtainable.

Transactions of the Medical Society of the State of North Carolina. Fifty-first Annual Meeting, 1904.

This creditable volume of nearly 600 pages has been prepared under the direction of a publication committee consisting of Dr. J. Howell Way, of Waynesville; Dr. George W. Pressly, of Charlotte, and Dr. H. McKee Tucker, of Raleigh. Besides addresses, reports, and the minutes of the meeting, it contains forty-five papers of a valuable character.

Miscellany.

Poor Beverages in the Philippines.—Military and naval surgeons have so vigorously condemned the vile native beverages sold to American soldiers and sailors in the Philippines and have so vividly described the terrible effects of those liquors upon persons using them that the civil authorities of the islands have very wisely enacted an ordinance making it unlawful in the province of Cavite for any person to give, sell or otherwise dispose of to enlisted men of the army, navy, or marine corps any of the so called native wines or liquors, and providing that any person violating the act shall be punishable by a fine of one hundred dollars, or imprisonment for six months, or both. This action of the insular authorities is highly commendable, says the *Army and Navy Journal*, for May 6, 1905, and we regret that it does not apply to the Philippine Islands in general, instead of to a single province in the Island of Luzon. It may be needed more in Cavite, perhaps, than elsewhere, for the reason that the seamen attached to the naval station there are con-

stantly exposed to danger at the vile saloons where vino, tuba, anisado, and other poisonous native beverages have hitherto been on sale, but the effects of those decoctions are so frightful that it would be a good thing if their sale to soldiers and sailors were absolutely prohibited everywhere in the islands. The use of those liquors by enlisted men of the army has greatly increased since the abolition of the canteen, and medical officers agree that they have never encountered intoxicants so degrading, both physically and morally, to the victims. The soldier who drinks beer in a saloon adjacent to the post where he is stationed is obliged to pay twenty-five cents a bottle for it, and as the price is virtually prohibitive he is frequently tempted to use vino, with the result that he falls a victim to the worst form of drunkenness known to medical observers. If the sale of such injurious beverages to our soldiers and sailors in the islands can be wholly prevented, every friend of the army and navy will have reason to be thankful.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending May 10, 1905:

- BILLINGS, W. C., Passed Assistant Surgeon. Relieved from duty at Quebec, Canada; directed to proceed to Seattle, Wash., and report to commanding officer of United States steamer *Perry* for temporary duty.
- BROCK, G. H., Pharmacist. Granted leave of absence for thirty days from May 18th.
- CARRINGTON, P. M., Surgeon. Detailed to represent the Service at meeting of the American Association for the Study and Prevention of Tuberculosis at Washington, D. C., May 18th to 19th.
- FOSTER, J. P. C., Acting Assistant Surgeon. Granted leave of absence for ten days from April 17th.
- GAHN, HENRY, Pharmacist. To report at Washington, D. C., for special temporary duty.
- HOLT, J. M., Passed Assistant Surgeon. Granted leave of absence, on account of sickness, for twenty-three days.
- KERR, J. W., Passed Assistant Surgeon. Relieved from duty at Ellis Island, N. Y.; directed to proceed to Quebec, Canada, for duty in office of the United States Commissioner of Immigration.
- LUMSDEN, L. L., Passed Assistant Surgeon. Relieved from duty at Philadelphia, Pa.; directed to proceed to Baltimore, Md., and report to commanding officer of United States practice ship *Chase* for temporary duty.
- PETTUS, W. J., Assistant Surgeon General. Granted leave of absence for two days from May 4th.
- ROBINSON, D. E., Passed Assistant Surgeon. Relieved from duty at Port Townsend Quarantine; directed to proceed to San Francisco, Cal., and report to commanding officer of United States steamer *Manning* for temporary duty. May 8, 1905.
- STANTON, J. G., Acting Assistant Surgeon. Granted leave of absence for eight days from May 10th.
- TROXLER, R. F., Pharmacist. To report to Medical Officer in Command, Marine Hospital, Port Townsend, Wash., for temporary duty.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 13, 1905:

HULL, H. F., Assistant Surgeon. Detached from the *Franklin* and ordered to the Naval Hospital, Philadelphia, Pa.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending May 13, 1905:

- ASHFORD, B. K., Captain and Assistant Surgeon. Reported at Albonite, P. R., on special duty with the Governor of Porto Rico.
- BAILY, HOWARD H., First Lieutenant and Assistant Surgeon. Left Fort Myer, Va., on ten days' leave of absence.
- FAUNTLEROY, P. C., Captain and Assistant Surgeon. Granted twenty days' leave of absence.
- HAYARD, VALERY, Colonel and Assistant Surgeon General. Returned to duty as Chief Surgeon of the Department of the East, from detached duty.
- MARROW, CHARLES E., First Lieutenant and Assistant Surgeon. Left Fort Sheridan, Ill., on thirty days' sick leave of absence.
- MASON, CHARLES F., Major and Surgeon. Appointed a member of the board of officers to select site for a new army post in the vicinity of Buffalo, N. Y.

MAUS, LOUIS M., Lieutenant Colonel and Deputy Surgeon General. Ordered to Fort Logan H. Roots, Ark., Fort Reno, O. T., and Fort Sill, O. T., on inspection duty.

MCCULLOCH, C. C., Jr., Major and Surgeon. Granted ten days' leave of absence.

OWEN, WILLIAM O., Major and Surgeon. Relieved from treatment at the Army and Navy General Hospital, Hot Springs, Ark., and ordered to join proper station, Fort Logan, Colo. Also granted three months' sick leave of absence.

PALMER, FRED W., First Lieutenant and Assistant Surgeon. Returned to the United States Rifle Range, Arcadia, Mo., from detached duty at Jefferson Barracks, Mo.

RENO, WILLIAM W., First Lieutenant and Assistant Surgeon. Relieved from temporary duty on the transport *Sumner* and ordered to return to his proper station in Fort Myer, Va.

RHOADS, THOMAS L., First Lieutenant and Assistant Surgeon. Left West Point, N. Y., on ten days' leave of absence.

SMITH, HERBERT M., First Lieutenant and Assistant Surgeon. Reported at Fort McDowell, Cal., for temporary duty.

TRUBY, A. E., Captain and Assistant Surgeon. Relieved from duty at Alcatraz Island, Cal., and ordered to the Presidio of San Francisco, Cal., for duty with Company B, Hospital Corps. Granted ten days' leave of absence.

WADHAMS, S. H., First Lieutenant and Assistant Surgeon. On being relieved from duty on the transport *Logan*, ordered to Alcatraz Island, Cal., for duty.

Births, Marriages, and Deaths.

Married.

DODD—ROBERTS.—In Boynton, Virginia, on Monday, May 1st, Dr. W. T. Dodd and Miss L. Fahy Roberts.

FOSTER—RUSSELL.—In Boston, Massachusetts, on Tuesday, May 9th, Dr. Michael George Foster, of London, and Mrs. Margaret Manning Russell.

REED—BAKER.—In Baltimore, Maryland, on Wednesday, May 3rd, Dr. Jacob W. Reed and Miss Edith L. Baker.

RHODES—JOHNSON.—In Baltimore, Maryland, James Mauran Rhodes, Jr., and Miss Ella Brock Johnson, daughter of Dr. Robert W. Johnson.

Died.

ALLEN.—In New Orleans, Louisiana, on Friday, April 28th, Dr. John Calvin Allen, in the forty-ninth year of his age.

CAMPBELL.—In Montreal, Canada, on Thursday, May 4th, Dr. Francis Wayland Campbell, in the sixty-ninth year of his age.

CAREY.—In Philadelphia, Pennsylvania, on Thursday, May 4th, Dr. Elias B. Carey, in the seventy-second year of his age.

DAVIS.—In New York, on Saturday, May 6th, Dr. Albert A. Davis, in the seventieth year of his age.

Goss.—In Chelsea, Vermont, Dr. Story N. Goss, in the seventy-fifth year of his age.

GRADY.—In Philadelphia, Pennsylvania, on Sunday, May 7th, Dr. James B. Grady, of Los Angeles.

HOOPLE.—In Brooklyn, N. Y., on Monday, May 8th, Dr. Heber N. Hoople, in the forty-ninth year of his age.

KING.—In St. Louis, Missouri, on Tuesday, May 2nd, Dr. Robert M. King, in the sixty-second year of his age.

NIXON.—In Biloxi, Mississippi, on Tuesday, May 9th, Dr. Oliver W. Nixon.

TROUTMAN.—In Somerville, New Jersey, on Saturday, May 6th, Dr. Seymour C. Troutman, in the eighty-fourth year of his age.

WALLACE.—In Fox Lake, Wisconsin, Dr. F. A. Wallace, in the eighty-ninth year of his age.

WARREN.—In Groton, Massachusetts, Dr. William B. Warren.

YOST.—In Youngstown, Ohio, on Tuesday, May 2nd, Dr. Joseph O. Yost, in the thirty-eighth year of his age.

INTERMITTENT ANGEIOSPASM ON THE BASIS OF CHRONIC MALARIA.

By FRITZ SCHWYZER, M. D.,

NEW YORK.

Malarial disease is one that has been recognized for centuries, and its clinical aspects and aetiology are as clear as those of any disease known to medical science. Although, therefore, it seems not easy to contribute to the knowledge of this affliction of mankind, I feel justified in publishing the following observations on a complexity of malarial symptoms, which, if not unknown to perhaps many physicians, have never been as clearly classified as they deserve. I mean the disturbance of the vasomotor nerves caused by chronic malaria, and will deal chiefly with the symptoms caused by an irritation of the vasoconstrictor nerves. This irritation of the vasomotor nerves can be compared to an irritation of the sensoric nerves, neuralgia, which causes a contraction of the arteries in a circumscribed portion of the body, or, as is the case during a chill, in all the peripheral arteries. If the contraction of the artery is very pronounced it leads to local ischæmias, and a consequence of this will be very diverse subjective symptoms according to the location of the arterial spasm. The whole disturbance may justly be designated as an angeiospastic form of chronic malaria.

Angeiospasm is to be found under many different conditions. They are quite frequent in neurasthenical and hysterical patients, and especially in the various forms of pure angeioneurosis which have been described of late. It is necessary to exclude all the forms mentioned before one can consider the malarial vasomotor disturbances which I characterize by the enlargement of the spleen, frequent, but generally light fever, anæmia, indications of melanosis, and, at times, by the periodicity of the angeiospastic attacks. The presence of plasmodium malarie is, of course, convincing, although it cannot be demonstrated in every case.

My first observation of angeiospastic malaria was made in 1903, in a very pronounced case. This case

enabled me to question for similar symptoms in patients with chronic malaria with the result that, within one year and a half, I found three more cases belonging to this group and as many others with indications of the same trouble. To lead the reader *in medias res* I shall give a description of my first, as well as of several other cases.

CASE I.—A man, European, eleven years in New York City, aged 39 years, with a malarial history of seven years' standing, otherwise quite strong; no venereal history. During a sojourn in the northern part of New York State, in August, 1903, he complained, for about a week, of great prostration. Upon slight exertion his temperature rose to 100° or 100½°. He had occasional neuralgias, yawning spells, and all the weariness and depressed feelings, the well known accompaniments of chronic malaria. He neglected to take quinine, hoping that the mountain air would cure him. One evening, about five o'clock, while reading in a hammock, he had a sudden feeling of numbness in his right arm, and although retaining the power of motion, that of sensation was almost gone. His arm felt as if it were "asleep," and there was a tingling sensation in it and in his hand. While he tried by moving his arm to restore to it its natural feeling, his right leg developed the same symptoms, and faintness and nausea forced him to lie down. Within a few minutes tingling and numbness of the tongue ensued, and gradually aphasia. This reached its height about fifteen minutes after the onset of the first symptoms. He lost his power of speech entirely, for about twenty minutes he was unable to pronounce or even to think one word, although fully conscious all the time. The queer feeling in his arm and leg gradually subsided, and about half an hour from the beginning of the attack his speech showed signs of improvement. In less than two hours the symptoms had all disappeared, except a pronounced prostration which may have been partly the outcome of the emotion caused by the seemingly dangerous character of the attack. A physician who was summoned called the whole trouble a slight cerebral hæmorrhage, although it was not possible to localize it.

Two days after, at the same hour, the patient had a very slight recurrence of the attack, and again, two days later, at the same hour, the trouble repeated itself, with slight aphasia which lasted scarcely ten minutes. The physician then changed his diagnosis and called the case neurasthenia.

I now had an opportunity to make a careful study of the case. The patient had all the symptoms of

chronic malaria, but although he was of rather a nervous temperament, and came of a somewhat neurotic family, up to his fortieth year he had never had any neurasthenic symptom. It seemed to me probable that the case must be some strange utterance of malaria, especially after the third attack in tertian type. There was, at that time, no possibility of testing the blood, but as I knew from former blood examinations that the patient had malarial plasmodia I commenced an antimalarial treatment. Large doses of quinine, about one and one half or two grammes a day made him feel much better, but in spite of these doses he had attacks of numbness and formication in arms and legs of more or less severity for several weeks, chiefly in the late afternoon. The true tertian type disappeared in about two weeks, and was followed by a more regular but milder quotidian type. The numbness and formication did not adhere to the right side alone, but attacked the left arm especially, and persisted there for quite a long time.

A few weeks after the first attack I was able to show the case to Dr. George W. Jacoby and Dr. J. Kaufman. Both agreed with me in the diagnosis of severe malaria which led to vasomotor disturbances and their consequence, *paræsthesia*. Our finding was: very large spleen, 9 by 17 cm., moderately enlarged liver, normal blood vessels, no arteriosclerosis, somewhat weakened heart action, slight dyspnoea, greyish yellow discoloration of the skin, and brown pigment, but no plasmodia in the blood, which could not be expected after the prolonged quinine treatment. The patient's temperature was normal before leaving his bed in the morning, but the slightest exertion sent it up to 99.6° or 100°, in rectum. Even for weeks after the first attack a slow walk resulted in a temperature of 100.5°.

A careful examination of the eyes by Dr. R. Denig, showed normal blood vessels and a normal field of vision. The urine contained a faint trace of albumin, but no casts. It took many weeks of severe quinine treatment and hypodermic administrations of arsenic before the patient felt himself again. The attacks of slight *paræsthesia* made themselves felt, off and on, until January, and even in the spring of 1904, six months after the first attack, a slight bronchitis brought back the old numbness for a time, each onset lasting for about half an hour or less. The temperatures of the patient were normal in the morning, i. e., 98.2° or 98.4° by rectum; in the evening, after a restful afternoon, they ranged from 98.8° to 98.6°, while as late as May, 1904, the evening temperature, after a good day's work, went up to 99.6°, 100°, or 101°. The faint trace of albumin found at the end of September, 1903, had disappeared by November, 1903, and since April, 1904, the general condition of the patient has been very good.

While in the Alps in August, 1904, he had a recurrence of the *paræsthesias*. The trouble commenced during a severe atmospheric disturbance, when the temperature dropped from summer heat to freezing, followed by a snowstorm. The angiospasm localized in the left arm chiefly, but also in the coronary arteries, causing attacks of cardiac asthma accompanied by moderate pain in the heart region. For one week the patient was scarcely able

to go up a slight incline, and he could not lie on his left side, or flat in bed. The symptoms disappeared after he had taken about 120 milligrammes of sodium arsenite in eight hypodermic doses, one every day.

CASE II.—A man, of German origin, fifty years resident in New York, aged 61 years, told me that in 1890 he had had some numbness and formication in the extremities, especially in the left arm and leg, but at times in the right one also. He went to a nerve specialist, and, after long therapeutical efforts, his case was diagnosed as incipient malarial polyneuritis, and was improved by prolonged quinine treatment. But ever since then the patient has had for a period each year, especially in the autumn, slight reminders of his old trouble in the form of *paræsthesias*, chiefly in the left leg. He had long given up the hope of a permanent cure. In December, 1903, he complained to me about numbness of the left side, arm and leg, he had a feeling as if rubber bands were bound tightly round them, of general weakness, and occasional feelings of faintness. He told me that the same condition had shown itself fourteen years before.

Physical Examination.—A well built man, tall, weighing about 170 pounds, heart and lungs showed no changes, heart sounds did not point to increased arterial pressure, all of them excluded any marked degree of arteriosclerosis. A careful examination of the palpable arteries of the body did not reveal any sclerotic condition. Liver normal in size, spleen large, the absolute dulness measuring 16 by 9 cm., stomach and intestines apparently normal, urine contained no albumin, sugar, or bile, and the amount of urea, uric acid, and salts in the twenty-four hours was normal. The fingers in several phalangeal joints showed slight arthritic changes (no gout), of pretty long standing, and seemingly non-progressive. I had occasion to examine the radial artery during an attack of severe numbness in his left arm, and found the left radial pulse to my touch distinctly smaller. The veins on the left side were much less filled than on the right side, and even the color of the skin showed that the blood supply in the left arm was considerably less than in the right. The blood pressure measured with Potain's sphygmomanometer showed in both radial arteries 19 cm. Hg. This sphygmogram of the two radial arteries spoke for itself. The left radial gave a much smaller tracing than the right. The patient complained of general lassitude, and with certain regularity had his good and bad days (tertian type), at times he felt a difficulty in speech, which made him timid of speaking in public.

The examination of the blood showed much pigment, but no plasmodia. Antimalarial treatment brought about a very marked improvement in four weeks, but then the effect of the quinine and arsenic seemed to be exhausted. During February, March, and April of 1904, the patient, although much improved, felt his old trouble quite often. In May the malarial symptoms were again so marked that I had to put him back to the antimalarial treatment, and then sent him to Oeynhausen in Germany to take a course of carbonic acid baths. The result of this hydropathic treatment was not encouraging, the symptoms of angiospasm did not disappear, and

even a long sojourn in the Alps brought no relief. The patient was very much discouraged when he returned to New York. On examination I found his spleen much smaller, his skin less pigmented, and his general condition good. No sign of malaria remained, the periodicity had disappeared, and I concluded that the primary malarial disturbance had led to true neurosis. I put him on an antineurotic treatment with glycerophosphate of calcium, which benefited him a great deal, but he still has occasional slight paræsthesias.

CASE III.—Mr. P., born in Vermont, aged 53 years, had had tuberculosis of the lungs twenty years before, and still suffered occasionally from bronchitis. He had had malaria ever since he has lived in New Jersey, perhaps twenty years. In November, 1903, he complained of severe malarial symptoms, chills and fever, pains all over, depression, and cold sweats.

The general examination revealed some remainders of tuberculosis, a cicatrix in the right apex, but no active tuberculosis. The heart quite normal in rhythm, frequency, and strength, and the heart sounds showed normal accentuation. There was no sign of arteriosclerosis; urine normal. The liver was slightly enlarged, the spleen measured 9 by 22 cm.

One morning he came to my office in great excitement because he had lost his speech when wishing to talk to his employees. On his way to business he had felt numbness in his right arm, also slightly in the right leg, symptoms which he knew well and did not mind. On arriving at his office his speech became heavy, and for a time he could not speak at all. When I saw him his speech was restored, only a slight difficulty in pronunciation remaining. The right radial pulse was distinctly smaller than the left one, and the skin of the right hand seemed to contain less blood than that of the left. In spite of the fact that he had had these attacks before but without aphasia, the patient thought that he was paralyzed. During the height of the attack he felt nauseated and faint. His blood contained a moderate number of plasmodia malariae, some pigment, and signs of rather severe anæmia. I at once commenced giving quinine and hypodermic injections of arsenic, and in about three weeks he was much improved. He has had no paræsthesias since then.

CASE IV.—G., French, fifteen years in the United States, aged 40 years and 6 months, a heavy drinker and smoker, under my treatment on account of gumma hepatitis, which had disappeared through prolonged mercury and iodide medication. In December, 1903, he complained to me that about every ten days he had a severe attack of chills and fever. I examined his blood during an attack of this kind, and found a moderate amount of plasmodia, quartan type. After his attacks, fornication and numbness in the right, and occasionally in the left arm and leg continued, and on one occasion he observed a marked difficulty in his speech. The spleen was very large. Quinine improved his condition rapidly, in a few days the paræsthesias were all gone. I do not know if this cure was permanent as I have not seen him since January, 1904; besides I should not call his case purely malarial. He may

have some cerebral endarteritis luetica, which might have caused a part, or all of the symptoms.

CASE V.—K., born in New York of European parents, aged 36 years, had been suffering from malaria for a number of years. Her temperature, of late, had been scarcely ever normal, always 99.5° in the morning, and 100.5° or 101° in the evening. She complained of attacks of numbness in her arms, especially in the left one, accompanied by nausea and faintness. These attacks came every second day, at the same hour, and had been going on for some time. The patient got alarmed at last, in the thought that she would become paralyzed.

I found her heart and arteries normal, a slight difference in the size of the radial pulse, the left being smaller than the right, a very large spleen, a greyish brown pigmentation of the skin, a pronounced anæmia, parasites in the blood of the tertian type, and the urine normal. She lost all the malarial symptoms after three months of antimalarial treatment, and in June, 1904, her temperatures were normal, the skin lighter in color, the spleen small. The paræsthesias had disappeared after four weeks of the treatment. In October, 1904, she was entirely well, and has remained so.

CASE VI.—R., European, in America for fifteen years, living in Hoboken, had, since 1895, irregular attacks of malarial fever, sometimes intermittens tertiana.

His skin was brownish gray, liver large, spleen very large. Of late he complained of repeated attacks of faintness, vertigo, and irregular chills. One day, in March, 1904, feeling tired and feverish, he went home where he lay down on a sofa. He fell asleep; when he awoke he did not feel his right leg at all, and fell when he tried to rise. His leg was not really paralyzed, only very numb. His right arm was also slightly affected in the same way, and his speech was much impaired. Next morning he felt better, but a slight weakness, nervousness, frequent attacks of vertigo, etc., persisted.

The urine showed 0.2 per cent. of glucose, the blood vessels were normal, as far as one can judge; the pupil of the right eye reacted to the light much more slowly than the left, and was usually rather the larger. The patient denied syphilis, and I had no reason to doubt his assertion, but the difference in the size of the pupils prompted me to give him potassium iodide, and, of course, antimalarial treatment as well. His sugar disappeared on very moderate antidiabetic diet. Since then his health has been very good.

I report this case chiefly on account of its complicated aspect. The apoplectiform attack could be explained by the diabetic tendencies, as well as by a possible lues, and I would never have thought of malaria as an ætiological factor, but for the cases just described. The patient certainly had no motor paralysis, as one would expect in luetic or diabetic apoplectic attacks, but I shall be obliged to leave the diagnosis open for several years to come. He had had no recurrence of the trouble up to April, 1905.

CASE VII.—A. R., brought up in Jersey City, aged 28 years, was robust until three years ago, when he began to be ailing. He had frequent chills,

general pains, and was usually very tired and depressed. In May, 1904, he complained to me of paræsthesias in his limbs. Four months before he had first noticed them in his feet, then in his arms also, and now often in his head and tongue. He had good and bad days alternately, and always slight fever, ranging from 99° to 101° .

Examination revealed a hard and very large spleen, large liver, slightly melanotic skin, and very anæmic blood, with plasmodia of the tertian type, and one semilunar body; the urine and blood vessels normal. Four weeks of antimalarial treatment brought some relief, but he is not yet entirely free from attacks of numbness.

CASE VIII.—W. M. R., born in Philadelphia, aged about 48 years, had a severe attack of malarial fever when eighteen years old. During that time he had attacks of vertigo, numbness in the right arm and leg, and difficulty in speaking. He has had several of these attacks in his later life, and, as he asserted, each time with malarial symptoms. I believed the attacks were malarial angeiospasm, although I cannot exclude hemicrania with spastic symptoms. (See *Semaine médicale*, August 10, 1904, Meige: "Migraine ophthalmique avec hémianopsie et aphasie transitoires.") Meige, also, explains his case as angeiospasm.

SYNOPSIS.

The eight cases described above, Nos. 1 to 8, exhibit a number of symptoms in common. Each shows a malarial history with repeated chills and fever; each shows the exterior signs of chronic malaria: the brownish gray pigmentation of the skin, and anæmia. In each the spleen is either large, or very large, and hard when palpable; in most of them the liver is enlarged. Cases Nos. 3, 4, 5, and 6 had irregular chills shortly before, or during the time of observation. Case No. 1 had frequent attacks of fever, but during the time of the angeiospasm, the patient showed a subcontinua for months, which ranged from 99° to 101° F., and a very mobile temperature, which rose on the slightest exertion. Case No. 2 had almost a normal temperature, Case No. 7, a subcontinua of 99° to 100.5° , with occasional rises to 101° . The blood of that patient no longer shows malarial plasmodia, but the spleen is still pretty large. The skin is pigmented and the patient looks anæmic. It seems as if he has been injured permanently, as if he would have great difficulty in getting out of his anæmic condition, and I would not be surprised if a secondary condition, like Banti's disease, would develop in him.

Case No. 8 I can mention only from the patient's own history, because when I saw him it was three weeks after his last attack, and I had no opportunity of examining him more closely. He had lived abroad for a number of years, and his general appearance certainly did not betray malaria; but he asserts that his first attack of numbness, etc., set in

during the time of his chills and fever, and that the later attacks were usually accompanied by malaise and fever, which he recognized as malarial.

The temperatures of these cases are not especially characteristic, but simply show the signs of chronic malaria, at times with acute exacerbation. In chronic malaria the temperature is usually not high, sometimes it is normal, generally rather above. The mobility of the temperature, that is to say the rise of temperature after even a slight exertion, is very characteristic of chronic malaria. We find the same conditions in tuberculosis cases.

In giving the history of my first case, I mentioned some of the diagnostic possibilities. In it I was obliged to reject: incipient polyneuritis, hysteria, neurasthenia, reflexneurosis, and ordinary angeioneurosis; last, but not least, arteriosclerosis and arteritis luetica, with all their consequences: cerebral hæmorrhage, embolism, thrombosis, and their disturbances in the peripheral circulation; further, intoxications, like uræmic poisoning, alcohol, tobacco, caffeine, etc. The latter were all excluded in my most severe cases, Nos. 1, 2, 3, 5, and 7, as were arteriosclerosis, and lues. I believe, that the diagnosis very frequently made in such cases is hysteria and neurasthenia, to both of which so many occult troubles are attributed. It is evident that in the above cases this diagnosis would be erroneous: hysteria does not cause a low, but continuous fever, although it is supposed, at times, to cause high temperatures. Neither does it cause the peculiar malarial look, nor melanosis, nor does it lead to enlargement of the spleen and liver. The anæsthetic zones of hysteria are more anæsthetic, often analgetic, they do not come and go in short attacks, and certainly not in the tertian type. A great difficulty in making a diagnosis will occur, when the patients with severe chronic malaria, especially its angeiospastic form, become neurasthenic, in consequence of their anæmia and prolonged malaise and suffering. It will then be hard to classify the symptoms into the two groups, and to say how much of the trouble is due to neurasthenia, and how much to malaria. The diagnosis between ordinary angeioneurosis and reflexneurosis and angeiospastic malaria, is evidently the presence, or the absence of malaria, and especially the type of the attacks.

Let us now look into the pathogenesis of the complexity of symptoms, which I wish to call the angeiospastic form of malaria. In describing Case No. 1 I have mentioned that the pathological process at first looked like apoplexy. But excepting the aphasia, there was no motor disturbance. The sensory disturbance lasted only a few hours, and could not be placed in any picture of cerebral hæmorrhage, embolism, or thrombosis. The symp-

toms were, in the first attacks, of a cerebral character (the aphasia); later peripheral (local paræsthesias, for instance, in the region of the ulnar nerve). It was not a polyneuritis (no pain, motor disturbances, or anæsthesia), in fact the picture in Case No. 1, or in the other cases, could not be explained by any purely nervous trouble. The symptoms most resembled those found in severe arteriosclerosis, or arterial lues, but neither of these processes was present in my principal cases.

It must, therefore, have been a functional disturbance of the circulation, which caused the symptoms in the blood vessels. There are two kinds of functional disturbances: contractions and dilations, the former leading to local anæmias, the latter to hyperæmias. In our cases it was contractions, or angeiospasm. Spasms of this kind explain the sudden onset of the paræsthesias and its sudden disappearance, and account for the variability of the symptoms.

Angeiospasm is quite frequent under many conditions, and are well known to cause local ischæmias, and their consequences, paræsthesias and anæsthesias. They occur in the cerebral arteries, and not infrequently in the coronary arteries, giving rise to false angina pectoris and cardiac asthma. They often occur in the extremities, and are not rare in the internal organs. They even influence the renal circulation, and the production of urine can be interrupted by angeiospasm.

With several of my patients I could clearly establish that, during the attacks, I had to deal with a spastic contraction of some of the arteries. In peripheral paræsthesias I found, on the affected side, the radial artery contracted and the pulse much smaller than on the normal side. I also found the blood pressure higher on the affected side, measured with Potain's sphygmomanometer in the radial artery; but this does not seem always to be the case. I took pulse tracings several times during the attacks, and found the affected pulse to be much smaller than normal, also much smaller than in the free interval. The blood pressure in the fingers, measured with Gaertner's tonometer, was invariably lower on the affected side.

The location of the spasms was, in our cases, either cerebral or peripheral. In Case No. 1, the first three attacks indicated plainly cerebral angeiospasm, while later the spasms were located in the arteries of the extremities. In Cases Nos. 3, 6, and 8, there were cerebral attacks also, while the cerebral symptoms observed in Cases Nos. 2, 5, and 7 pointed more to a disturbance of the general blood distribution, which manifested itself by anæmia of the central nervous system. So I consider the

angeiospasm but indirectly responsible for the dizziness, nausea, faintness, etc.

It now remains to show that, in our cases, the angeiospasm were due to malaria. The toxins produced by malarial germs have a great tendency to attack the nervous system. Neuralgias, especially of the intermittent forms, are amongst the most frequent utterances of chronic malarial infection, and even malarial neuritis and polyneuritis are not rare. Why should not the vasomotor nerves, therefore, suffer under the influence of the malarial toxins, and lead to either a contraction or dilatation of the arteries, according to whether the vasoconstrictors or vasodilators are irritated, or paralyzed? Malaria, *eo ipso*, is a great strain on the peripheral vasomotor nervous system, as chills and chilly sensations are always accompanied by general vasoconstriction, while during the subsequent fever and perspiration, the blood vessels of the periphery show extreme dilatation. It is possible that in our cases the angiocontractions represent the chill, and this would explain the intermittent attacks.

In some patients we find the condition of the blood vessels reversed: we find extreme vasodilatation appearing in intermittent attacks. Of course, locally, we find the opposite of ischæmia, we find enormous hyperæmias and swelling of the affected parts. I can mention a few instances of the hyperæmic type.

1. A patient in my service at St. Francis Hospital a few years ago complained of an intermittent swelling of the tongue. Every second day, at six o'clock in the evening, her tongue swelled up to such a size that she had to keep her mouth open to allow it to protrude to keep from suffocating. Quinine, given after the third attack, brought prompt relief. The spleen was very large; blood slides were not taken.

2. Two years ago I saw a similar case in private practice. A lady of about 35 years of age, complained to me about choking sensations, pain in the throat, and swelling of the tongue. But when I examined her I could see neither redness nor swelling of the pharynx or tongue. A few days later she told me that her trouble continued and upon questioning her more closely, I found that she had an intermittent swelling of the pharynx and tongue, the former becoming dark red during the attacks. This came every day, and each time an hour earlier than the day before. Her tongue swelled so that she had to keep her mouth open. I found the spleen very large, and prescribed quinine, which cured her in two days.

3. A case observed by Dr. J. Kaufman, showed intermittent swelling of the thyroid gland. The swelling was so great, and the tension of the gland, at times, so painful, that a prominent surgeon suspected an abscess or tumor. Several probatory punctures proved negative. As the patient's spleen was very large, quinine was prescribed with success; the gland resumed its normal size and consistence, and for six years has shown no signs of disturbance.

One might compare the attacks of vasodilatation to the final state of the malarial attack. It is well known that a malarial attack begins with vasoconstriction and high blood pressure during the chill, and the height of the fever. Then the blood pressure sinks below the normal, because the blood vessels dilate very much. Therefore, it would be important to measure the blood pressure in cases of intermittent malarial attacks of local hyperæmias, and that might decide the correctness of my supposition.

It would be mere guesswork for me to venture an opinion on the issue of angeiospastic malaria. It is certainly a severe strain on the blood vessels, and possibly the endothelium will suffer and arteriosclerosis be the consequence.

It is scarcely necessary to find further proofs of the angeiospastic nature of the symptoms of my most pronounced cases, Nos. 1, 2, 3, 5, 7, and 8. As I said above, Case No. 2 ran more into plain vasomotor neurosis, and Case No. 4 was uncertain in its nature, as syphilis was present, and as I could not continue my observations on the patient. Case No. 6 was so complicated, being slightly diabetic, malarial, and possibly syphilitic, that I will not mention it as a purely malarial angeiospasm.

Severe angeiospasmus must of necessity lead to hyperæmias somewhere else, as the blood is not compressible. It is but natural to surmise that the abdominal circulation, the great regulator of the blood pressure, can be overloaded during the vasoconstriction. In Case No. 1 I could clearly observe the truth of this supposition. During a spasm involving the extremities of the left side, the patient had a desire to defecate, and emptied about 100 c.c. of pure blood from a small hæmorrhoid. He had never before passed more than a few drops of blood from his rectum, and that only at long intervals.

If luetic patients, No. 4, and possibly No. 6, are attacked by malarial angeiospasmus it is advisable to give the treatments for both malaria and syphilis simultaneously. With heavy smokers, like No. 8, it will be difficult to make a distinction between tobacco poisoning and malaria. I would never have attributed to malaria any of the influence in that case, but for the anamnesias which clearly described the first attack as occurring during pronounced intermittent fever.

Another issue of angeiospastic malaria seems, as Case No. 2 shows clearly, and Case No. 7 probably, a gradual development of true angeio-neurosis, which remains either constantly or comes in absolutely irregular attacks, and which cannot be benefited by antimalarial treatment. Case No. 2 has, since I wrote this article, improved wonderfully under antineurotic treatment, while the same

measures taken in true malaria had no more influence at all.

The treatment of angeiospastic malaria does not differ from that of chronic malaria in general. Quinine has a good effect during severe attacks, but later on I have used it without much result. Arsenic then proved more efficacious, especially when given hypodermically.

Medical literature on malaria reports a great number of cases with nervous symptoms, and amongst them apoplectic attacks due to that disease. Some of them accompanied, or substituted ordinary attacks of malarial fever, and left no trace. Others led to permanent lesions. Landouzy reports several cases of intermittent paralysis. Such cases are explained, in literature, by thrombosis of the cerebral blood vessels with parasites, or hæmorrhages due to high pressure, or as an effect of toxins. From my experiences I do not doubt that many of the cases of intermittent transitory paralysis, especially as far as they are sensory, belong to the class which I designate as an angeiospastic form of malaria, while the more permanent lesions may be parasitic embolisms, or ordinary apoplectic attacks that are not dependent on malaria, but are, perhaps, hastened by the vasomotor disturbance during the malarial attack.

54 EAST FIFTY-EIGHTH STREET.

Mortality of Michigan During April, 1905.—

The total number of deaths returned to the Michigan department of State for the month of April was 3,022, a decrease of 345 from the number returned for the preceding month. The death rate was only 14.4 per 1,000 population, as compared with 15.5 for March and 15.7 for April, 1904. There were 432 deaths of infants under one year of age, 171 deaths of children aged one to four years, inclusive, and 934 deaths of elderly persons over 65 years old. A marked diminution appears in the deaths of infants under one year. Important causes of deaths were as follows: Tuberculosis of lungs, 243; other forms of tuberculosis, 34; typhoid fever, 38; diphtheria and croup, 24; scarlet fever, 10; measles, 15; whooping cough, 7; pneumonia, 228; meningitis, 57; influenza, 72; cancer, 140; accidents and violence, 147. A slight increase appears in the mortality from typhoid fever, and considerable decrease in the number of deaths returned from pneumonia and influenza. Meningitis caused 57 deaths during the month, as compared with 54 for March. There were four deaths from smallpox distributed as follows: One in Alpena city, Alpena county; one in Dorr township, Allegan county; one in Walker township, Kent county; and one in the city of Grand Rapids.

ACUTE APPENDICITIS.*

By LEON BRINKMANN, M. D.,

PHILADELPHIA.

I present the subject of acute appendicitis in a form that will appeal more directly to the general practitioner. Although much has been written upon this subject, the last word is far from having been said. Anything which may tend to throw additional light upon the early recognition of acute appendicitis will, in the end, tend to lessen the mortality. To produce this reduction in the mortality we all agree that early operation is the surest means of avoiding complications, and by instituting prompt surgical interference in the early hours of the attack the mortality of the disease will be reduced to the minimum, which should be about 1 per cent. instead of from 4 to 20 per cent. in the acute cases.

The responsibility of failure to resort to early surgical interference in acute appendicitis may be classified as due to: (1) The patient's neglect in failing to send for a physician early enough in the disease. (2) The physician's inability to recognize the disease at the first visit. (3) The patient's or physician's repugnance to surgical measures. (4) The hope that something may turn up to produce recovery.

(1) If the responsibility is due to the patient's failure to secure proper medical attendance at the onset of an acute attack of appendicitis, and there is a further delay in the treatment by procrastination, this class of cases will form a nucleus for a mortality which cannot be eliminated. There is a very large class of cases of acute appendicitis which demands instant surgical interference after the onset of the disease, owing to the severe type of the infection, to early perforation, or to gangrene, and in which the patient's only hope for a prompt recovery is by immediate operation within the first ten or twelve hours after the onset.

(2) The physician's inability to recognize the disease at the first visit represents a state of affairs that, after such an exhaustive discussion of the subject has been before the medical world for the past decade, seems almost incredible. I will admit in very exceptional instances there may be a case in which the diagnosis is in doubt. There should not, however, in the average case of appendicitis be any hesitancy or doubt expressed in making the diagnosis after a careful examination of the individual. Failure should be ascribed to ignorance or neglect; in either instance it is inexcusable.

(3) The patient's or physician's repugnance to

surgical measures: Undoubtedly there is a certain percentage of people who would under no circumstance permit the performance of a surgical operation upon their persons. This class we cannot consider in the mortality of the disease. There is, however, a much larger percentage who will not permit surgical measures to be adopted until it meets with their preference, or who will permit it as a last resource notwithstanding the advice of the medical attendant. The latter class of patients should be dealt with in a manner in which they deserve, as no conscientious medical practitioner ought to permit his patients to dictate to him what they believe to be the proper course to pursue. The physician would better sever all connections with such a case, thereby avoiding the unnecessary responsibility which he will otherwise ultimately have to shoulder if the case terminates fatally. While it is the duty of the surgeon to alleviate suffering and distress, and to restore the sick to usefulness, I would not, under such circumstances, blame him if he refused operation as a last resort. Operation done upon patients with one foot in the grave with the hope of pulling the other foot out is usually the means of adding additional and unnecessary mortality and stigmata to surgery, especially in those instances in which the patient's dissent was the factor in the delay.

In speaking of the physician's repugnance to surgical interference I can in no other way account for the many deplorable cases which are referred for operation to the surgeon *in extremis*, sent by those misguided doctors who do not believe in the propriety of operation at any stage; by those who believe in waiting until the case is ripe, until a huge abscess has formed, until a second or third attack, or, lastly, trusting that the case will subside and permit an interval operation which is attended by no risk (?), providing the patient survives the attack.

That appendicitis has been determined a surgical affection is the consensus of opinion among medical leaders throughout this country, and yet the disease is treated medically. Why? The answer resolves itself into a lack of confidence in the ability to diagnose the disease, to a lack of assurance as to the ultimate effect of surgery, or to a repugnance for surgical intervention. Which is it?

The spirit of antagonism displayed to surgical interference in acute appendicitis by the medical practitioner is inexplicable in many instances in the face of the patient's apparent condition. When we consider the extraordinary statements made by some, that they have never lost a case of

* Read at the meeting of the Philadelphia County Medical Society, January 27, 1904.

acute appendicitis, and have never had even one of them operated in, it seems as if they certainly had a most remarkable sequence of cases, if they were all of appendicitis. A second class of physicians depends upon the chances the patient has to get well without operation, not counting upon the balance of the chances against the patient occasioned by the delay. In a case recently seen by the writer, the physician took the stand that the patient had seventy-five chances to get well without operation, although he stated he would pass several very anxious days until convalescence was assured. When pressed for an opinion as to the patient's chances by immediate operation, he thought they were from 99.5 to 100 to get well. It seems that the physician was willing to assume a risk for the patient of one out of four chances merely to avoid an operation.

Operation revealed an acutely inflamed appendix with gangrenous involvement of its mucous and submucous coats and the organ filled with foul smelling pus. The appendix was removed through a small incision; drainage was unnecessary; recovery uneventful. This is a single illustration of a large group of cases which under the ordinary or usual medical procrastination would have terminated fatally from a so called fulminating appendicitis as kind nature, the savior of so many cases, had failed to protect the peritoneal cavity by lymph or adhesions.

There are but few patients with acute appendicitis too ill to contraindicate the operation, unless absolutely moribund. I am satisfied that in the past I have refused to operate in cases in which there were present symptoms of advanced general peritonitis. During the past year I have operated in fifteen such cases, and am happy to state that ten patients recovered. One of these was that of a child that had been ill for two weeks, was much distended, suffered excruciating pain, with a temperature of 104° F. and a pulse of 160. Local anæsthesia was employed, the purulent fluid in the peritoneal cavity evacuated, and drainage introduced. This child survived the operation but six hours notwithstanding the fact that the simplest treatment was resorted to. In the remaining fourteen cases there were all the evidences of general peritonitis, although I could not positively affirm that every square inch of the peritonæum was infected.

(4) The hope that something may turn up. It has been said that hope and faith are the foundations of religion. We must not, however, employ our hope and faith in direct violation to conviction. It is a fact that a great many cases of catarrhal appendicitis are not of sufficient gravity

to warrant the patient in sending for his medical attendant, owing to the transient character of the pain. That a fairly large percentage of cases of acute appendicitis do not stop at the catarrhal stage is attested by the increasing statistics of operations; the many cases of circumscribed abscess, perforation, gangrene of the appendix, general peritonitis, lymphatic infection, and of the remote consequences of the disease, all form too vivid a picture to allow hope to sway our judgment against operation while waiting for something to turn up, which may, at best, defer the inevitable. The best thing that could happen would be an intelligent physician to point out the urgent necessity for intervention and thus bring about a cure and with it the conviction that this was the best means to adopt.

The remarkable unanimity of opinion among surgeons who are familiar with the subject of acute appendicitis in declaring that early operation is the only means whereby a reduction in the mortality may be accomplished, makes it all the more important to familiarize ourselves with the early characteristics of the disease and its progressive phenomena.

The apparent unfamiliarity of the average physician with the early symptoms of acute appendicitis and with the changes of the symptoms as the disease progresses accounts, in a measure, for the inability to make a diagnosis. Every physician is, or should be, familiar with the cardinal symptoms of the disease, viz., pain, tenderness, and rigidity, which, varying in location according to the stage of the disease, the position which the inflamed appendix holds, and the personal idiosyncrasy of the individual to the effects of sepsis, are the determining factors in arriving at a diagnosis after excluding any other abdominal condition with which it may be confounded.

The pain in acute appendicitis is not confined to any fixed point within the abdominal cavity; while it is true that in the majority of cases it is located in the right iliac fossa late in the disease, the early pain in acute appendicitis will be found in the epigastric, umbilical, suprapubic, left iliac, hepatic, or right lumbar regions.

The nature of the pain at the onset is usually of a colicky character, and the patient complains of cramps. These cramp-like pains are paroxysmal and intermittent, increasing in severity with shorter intervals between the seizures, and may be attended with either nausea or vomiting or with both; they are, however, not constantly present.

The onset of an abscess is marked by a very material increase in the pain, located at and con-

fined to the immediate vicinity of the abscess. A sudden cessation of pain is indicative of perforation or a rupture of the appendix, particularly if associated with sudden depression.

A decrease in the amount of pain and a persistence of the rigidity mean that gangrene has set in.

When there is a diffused pain late in the attack and a commencing rigidity of the abdominal walls (stiffness) it marks the advent of a commencing general peritonitis.

The tenderness in acute appendicitis varies in degree quite as much as does the pain. In the very early hours of the affection the tenderness is not so marked and might be overlooked by one not familiar with the quality and quantity present at this time. If, however, the tenderness is associated with the pain and other phenomena of the disease at this particular stage, slight rigidity and nausea or vomiting, one can scarcely be mistaken. As time passes and if the disease is progressive, then the tenderness becomes more marked, increasing each hour; located as it is over the site of the appendix, it makes it more possible to locate the organ by the sense of touch. In cases with fecal concretions or foreign bodies and in the presence of localized abscess, the tenderness is most marked, the patient wincing at the slightest pressure and drawing away if much force is brought to bear over this region. When the appendix is situated in the pelvis, then we may expect to find the tenderness in the left iliac or suprapubic region. If the tenderness is in the umbilical zone the appendix is either behind the mesentery or points upward toward the gall bladder. If the base of the appendix is involved, then we may in all instances find the tenderness in the right iliac fossa.

The amount of rigidity, like the tenderness, varies according to the stage of the disease and the intensity of the inflammation within. At the onset of an attack of acute appendicitis the rigidity is very slight and can only be elicited by the slightest pressure made with the finger tips over the portion of the abdomen in which the appendix is located. If, however, the appendix is situated in the pelvis the rigidity will be most marked over the lower portion of the left rectus muscle. The fact that the rigidity is often overlooked is easily explained by the method employed in the endeavor to find it, too much force being exerted in the effort. As the disease progresses, the rigidity becomes more marked and more easily defined. I quite recently saw a young woman about one hour after the onset of the attack, and discovered upon palpation of the ab-

domen a most marked, progressive rigidity over the entire right iliac region. I was unable, for reasons over which I had no control, to secure operation until eighteen hours had elapsed, and found a completely gangrenous organ present.

We cannot place too much reliance upon what might be called surface indications to determine how severe an attack of appendicitis will ensue. One individual will present all the phenomena of a most severe type of infection with excessive pain, tenderness, rigidity, nausea, and vomiting, with high temperature and rapid pulse, and yet an operation will reveal a small, engorged appendix without any circumappendiceal inflammation and without pus. This has been ascribed to the personal idiosyncrasy of the individual to sepsis. I believe, however, that it is due to some particular type of infection, either the *B. coli communis* or the streptococcus, or a combination of both, in which the operation has anticipated an extraappendiceal invasion.

In other instances individuals will have a progressive appendicitis with destructive changes going on without any particular grave or alarming symptoms appearing until late in the disease. On more than one occasion I have seen patients walking about, experiencing but slight discomfort, in whom I have found quite a large circumscribed abscess.

The danger in appendicitis is not alone from the formation of an abscess, but also from the plastic material thrown out by nature to protect the peritoneal cavity from infection. Upon the evacuation of a pus collection the plastic material forming a part of the abscess wall contracts in the process of obliteration of the cavity, and herein lies the danger, for an acute internal intestinal obstruction is liable to occur if the bowel is included in the abscess wall, and I might say that this is the usual state of affairs. Therefore, the danger of acute obstruction is ever present in all cases of circumscribed abscess. Further comment is unnecessary in reference to this complication other than to remark that early interference, before a collection is permitted to develop, would obviate this danger.

The ability to tell with any certainty how far the disease has progressed or that the patient will recover from an attack of appendicitis is beyond human skill, and is dealing with the disease and the patient in a hazardous manner. There are some physicians, and some surgeons as well, who delude themselves with the idea that they possess this power. These men in a large measure must face the responsibility for the continued high mortality in the disease, because, by their acts as well

as by their influence on other physicians, they allow a certain latitude to those who are always seeking some justification for deferring operation until it is either too late or is attended with great danger to the patient. When a conflagration is in progress the owner of the property undergoing destruction would certainly and properly lay the blame upon those whose duty it was to secure the means of extinguishing the fire, which in the course of a short time would consume his goods if they failed to procure such means.

We can replace goods lost by fire, but we cannot restore a life consumed in an appendiceal conflagration, and it is just what will occur in a certain proportion of cases if the physician or surgeon will presume to guess just how much the fire of an appendiceal volcano will consume. It has been the experience of many of us whose patients were apparently recovering from an attack of appendicitis, to be much chagrined by a rekindling of the inflammatory process, which was succeeded by a general peritonitis from a perforation of the appendix, the case ending in death; all of which might have been avoided by early operation. This is one of the dangers of waiting for the interval operation, the opportunity for which sometimes never comes.

There is no doubt in my mind that the so called cases of fulminating appendicitis are those in which there have been previous attacks which were unrecognized, and in which there remained a nidus of the primary attack only awaiting a favorable opportunity to rekindle. The number of cases operated in in the interval between the attacks has led to a more careful research as to the determination of the cause of the fulminant type, with the result that a fairly large number of cases have demonstrated either the presence of pus in varying quantities in the cavity of the organ, the presence of a cystic and strictured organ, or the occurrence of faecal concretions imbedded in the organ with the eroded and ulcerated mucous lining and one or more spots of pressure necrosis, leaving the peritoneal coat as the only barrier between the contents of the appendix and the peritoneal cavity.

The diagnosis of appendicitis is, as I have before stated, an easy one to make with but few exceptions, and the border line cases, if they may be so styled, are of such a character as to require abdominal section quite as urgently. When we consider that appendicitis is the most common acute intraabdominal disease, and if when brought in contact with any acute abdominal colic we should bear appendicitis in mind as the first possibility until other conditions with which it may

be confounded are excluded, the diagnosis will be greatly simplified.

I have found from experience that there are but few conditions in the male which will so closely simulate acute appendicitis as to require consideration in arriving at the diagnosis; these are acute inflammation of the gall bladder and its ducts, pancreatitis, stone in the kidney or ureter, hernia, intestinal obstruction; the various pelvic conditions resulting from inflammation of the Fallopian tubes and ectopic pregnancy in the female.

There is a sequence of symptoms in acute appendicitis which is not found in other diseases already enumerated. The pain, tenderness, and rigidity are not so marked, and if we note the difference in the progressive phenomena, as I have tried to make clear in the early portion of this paper, I cannot conceive how one can fail to make the diagnosis.

I wish to draw attention to two facts in making a diagnosis, which are not generally brought out in the discussion of this subject. One is the cause for the slight pain experienced by some notwithstanding the fact that an abscess is present. When the inflammatory process includes the parietal peritonæum there is always a greater amount of pain, and also increased rigidity; if the disease is deep within the abdominal cavity and surrounded by coils of intestines, the pain and rigidity are not so marked.

The only purely medical condition with which appendicitis may be confounded is the onset of pneumonia. I have found in quite a few instances, when called in consultation in cases of supposed appendicitis, a beginning pneumonia with acute paroxysmal pain in the right iliac fossa, which, however, was not associated with the other phenomena of appendicitis. Examination of the chest revealed the early phenomena of pneumonia. This is particularly of importance in children, in whom I have found this condition four times.

In discussing the treatment of appendicitis I will not waste time in describing methods with which all of us are more or less familiar, nor speak of medical means of combating the disease, except to remark that this is a surgical affection and requires surgical measures to insure complete relief.

I do not believe that any patient with acute appendicitis should be refused operation unless actually moribund. As I have previously stated in this paper, I have operated in fifteen cases, the patients being in *extremis*, ten of whom recovered. All of these patients presented unmistakable evidences of general peritonitis; one was so clearly

moribund that the anæsthetizer expected a fatal result from the administration of the anæsthetic. The best result that I expected in this instance was a prolongation of life. There was a gangrenous appendix separated from the cæcum at its base, pus and faecal matter in the peritoneal cavity, and yet this patient recovered after a three months' convalescence.

In conclusion, I wish to enter a pronounced protest against the Ochsner treatment of appendicitis; the plan of the starvation treatment without the intervention by surgical means until late in the disease violates the basic principles of good surgery. When we are confronted by the products of inflammation and bacterial action, it is evident that until these are disposed of by operation resolution will not take place. If delay is resorted to, experience shows that there is always an increase in the amount of purulent material, that the area of tissue involvement will be increased, that the inflammatory changes in the contiguous structures will be proportionately greater, that the organization of the adhesions will be firmer, and the disposal thereof will greatly endanger the structures involved.

When we consider further that patients live for a period varying from three or four days to one or two weeks after a more or less circumscribed peritonitis has developed, and then die either from the shock of a late operation or from neglect to operate, it is self evident that had surgical interference been adopted instead of trying speculative measures one would have nothing with which to reproach oneself.

One of Ochsner's main points in advocacy of the starvation plan is the prevention of peristalsis, thus avoiding a further contamination of the peritoneal cavity. If we will pause for a moment and carefully review the other possible means of spreading the infection within the peritoneal cavity, one of the strongest arguments for the treatment falls flat. The action of the diaphragm in the act of respiration, inspiration, or expiration has a greater or less tendency to siphon action on the contents of the abdominal cavity, which is clearly noted in the performance of any abdominal operation, hence there will be bowel movement without peristalsis. The peritoneal cavity contains a quantity of fluid which in the acute infective process of a peritonitis offers the very best culture medium for the growth of microorganisms, and as the contents of the abdominal cavity are bathed in this fluid and each act of respiration displaces it to some extent, it will be readily seen how this is an additional factor in the spread of the infection. The remaining method of infec-

tion is through continuity and contiguity of tissue. We cannot limit the migration of the bacteria or the invasion of the germ by inhibition of peristalsis.

Dr. Ochsner states further that large nemata should never be given, for fear of rupture of an abscess or a circumscribed collection. This, to my mind, is a clearly defined proposition for operation instead of delay. He further states that when neither food nor medicine has been administered from the onset of the disease, his mortality has been *nil* in acute cases. I must say that I have yet to see the case of appendicitis in which some household remedy has not been administered prior to the visit of the medical attendant, or even after treatment has been instituted by the physician in attendance. Those cases which would recover by physiological rest may be classed among those which it is the lot of the ordinary surgeon never to see. Ochsner states further that by abstention from food and lavage operation is made easier for the surgeon. I fail to see whereby this abstention will in any manner facilitate operation or help the operator. I certainly have never found sufficient peristaltic movement of the bowels to be appreciable in any degree whatsoever, or any faecal accumulation in the cæcum to embarrass the operation.

I do not for one moment want it understood from my remarks that Dr. Ochsner does not favor early operation. He does, but he places a time limit after which operation should be deferred until all acute inflammatory action has subsided.

Cooper Medical College, San Francisco, has graduated the following:

Walter Clement Alvarez, of Honolulu, H. I.; Archibald Anand Atkinson, A. B., of San Rafael; John Irving Beattie, of Santa Clara; Adolph Berg, of San Francisco; Ralph Percy Bernard, of San Francisco; Arthur Phinney Calhoun, of Seattle, Wash.; William Leon Channell, of Oakland; Willis Hiram Corson, of Issaquah, Wash.; Dorothea Willson Dekau, of Benicia; Percival Dolman, B. S., of Berkeley; Edwin Wood Earing, of Los Angeles; Frank Weston Edmonds, of Berkeley; Julius Columbus Egeberg, of San Francisco; John Stanley Hanlon, of San Francisco; Atlas Thompson Hembree, of Windsor; Reuben Heywood Hunt, of San Francisco; Peter Nathaniel Jacobson, B. S., of Healdsburg; Harry Clifford Loos, of San Francisco; Thaddeus M. McNamara, Jr., A. B., of Oakland; Albert Henry McNulty, of Fortuna; Edwin Merrithew, of Gold Run; Roy Henry Morris, of San Francisco; Archibald Leonard Offield, of San José; Joseph Bethencourt Perry, of Haywards; William Quinn, of San Francisco; William James Quinn, of Beatrice; Alva Jacob Remmel, B. S., of Alameda; Frank Holmes Smith, of San Francisco; John Waldo Snoke, of Seattle, Wash.; Aly May Spencer, Ph. B., of Pueblo, Colo.; Harry Lesel Swauger, of Oakland; Mary C. Taylor, of Stockton; Zilda Turner, of New Zealand; Calvin Albert Walker, of San Francisco; Harold Staniford Warren, of San Francisco; Philip Henry Weber, of Pomona; Irving Scott Zeimer, of Oakland.

THE SURGICAL PARADOX.

By ELY VAN DE WARKER, M. D.,

SYRACUSE, N. Y.

The differences between Dr. Daniel H. Craig, of Boston, and myself are so slight that the careless reader might feel justified in regarding Dr. Craig's kindly notice of my paper on the Dangerous Operation of Uterine Curettement as a waste of time; or, that this criticism on a paper contributed by him to the *New York Medical Journal and Philadelphia Medical Journal*, for March 19, 1904, bearing the same title, plus a suggestive mark of interrogation, was even less called for.

Slight as these differences may be they are vital to my contention that in uterine curettement we have a surgical proceeding inherently dangerous. When we admit that an operation is of such a character, or that the instruments necessary to its performance are of such a nature, that the best among us may do something that we did not intend doing, the mere fact that such an error was not always attended by fatal results in no way lessens the potential danger of the procedure.

I do not believe that there is a gynecologist in the land who will regard with complacency an accidental puncture of the uterine wall. All must be in accord with the author of the paper that such accidents occur and no harm is done; and we must agree with him in his statement that the dull curette may perforate the uterine wall as readily as the sharp. Nearly all of the accidents that have occurred within my personal knowledge were due to forcible dilatation which may occur in experienced hands. In abdominal surgery we have the reverse of these conditions. Here we are dealing with an operation of precision. We can see and feel what is before us and deal with it directly. In curettement we have an operation of indecision. With touch prolonged to the end of a piece of steel, with uterine tissue forcibly stretched by the action of an automatic instrument, sometimes actuated by a screw instead of the pressure of the hand, guided by neither sight nor touch, the surgeon cannot be decided as to what he is doing. The only safe thing about it is that he brings to his task trained muscles and ripe experience.

The division of operative gynecology into major and minor may have a certain influence in inducing inexperienced men to attempt the operation. This will not, however, explain the fact that two of the men referred to in my article of October 10, 1903, were attached to hospital staffs, one in a large city and the other in a small town. These men were doing "major" surgery.

One of the men, Dr. Craig none too severely

criticises when he says that "of an individual who fails to recognize the intestine when he has it in his sight and in his hands, and proceeds to scrape a hole in it, nothing in this connection need be said." This, however, is the very connection in which he must be reckoned with. "Any operation," our author concludes, "would be dangerous in such hands and no conclusions need be drawn as to the danger of such occurrences." This man was an abdominal surgeon and was doing this class of work with average success. The other man, who lives not many miles from Boston, is also a hospital surgeon and doing abdominal work with credit to himself and to his hospital, I am told.

It is very evident that it will not do to reach hasty conclusions in this matter; nor will it simplify the solution of the problem to say that curettement is safe in safe hands. We conclude from these facts that one may operate with the average safety in one department of gynecic surgery and be absolutely unsafe in another. Is this anomalous state of affairs due to the operator alone, or may it be due to the nature of the operation and the character of the instruments employed, or is it a mixed condition involving all?

Judging from the class of work in general surgery that I see about me, the best is done by the physicians who are good mechanics and who began young; the poor work is done by physicians approaching middle life who have gone wrong. Every man who has bestowed some normal indwelling upon his own limitations ought to realize that he can neither train old muscles to do new things nor can he educate into being new special faculties. Excepting one, all of the operations referred to in my paper were performed by men who became gynecologists at or past middle life.

Dr. Craig describes a carefully planned series of antiseptic precautions in preparing a patient for curettement. The result is that he never has the septic complications that so often occur in the surgical work of the inexperienced surgeon. Our author is perfectly right in stating that these precautions would make the operation safe from sepsis at any hands. This is the view taken by the text book writer and the teacher. I feel assured that this is a mistake. The experienced surgeon thinks in terms of his antiseptic technique; each act is a step as it were to a logical conclusion. What he does is the result of conviction induced by long and patient self training, rather than by teaching. The mistake exists in the fact that they assume that the old doctor can be induced to follow these essentials in every detail by teach-

ing instead of by training. He believes that he has followed every step when he has not. What appears to him as so very simple is really complicated, but its complexity has escaped him. It is not unusual for him to return to his home firmly convinced that there is a lot of nonsense in so much antiseptic fuss over so simple an operation. He has been taught and what is teaching for unless to enable him to use his mind? I have seen these men operate and I have been convinced that their preparation of the patient was regarded as a waste of time. Take the dilator, for instance. Our author can teach its use and the belated postgraduate can see him use it, but can any form of teaching yet devised convey to his mind, not the degree of force that he ought to use, but the actual amount that he is exerting with the instrument? The curette, blunt or sharp, is another thing that he is taught, not trained, to use. I have long ago defined practical gynecology to be simply a highly trained and differentiated sense of touch. Can fingers which have never acquired this gain any idea of consistence or resistance with such a touch prolonged to the end of a steel wire? This cannot be taught, it must be acquired by training.

It is doubtful if the author has added anything to the general belief in the safety of uterine curettement by referring to the frequency of puncture of the walls of the organ without evil results. Already there is a growing tendency to belittle the dangers of the operation. We all know that such accidents do happen even with experienced operators. This fact alone, if we had no others, is sufficient to prove that there are positive and inherent dangers in the operation. I think Dr. Craig hardly grasped the motive of my paper. It was simply this: that college and postgraduate teachers, as well as the textbook writers, regard the operation too lightly. They have minimized its dangers to very nearly a negligible quantity. Very little is said to caution the untrained man that he is dealing with a dangerous procedure. We will always have the untrained operator with us, and there are no conscientious, trained surgeons who do not deplore the fact.

The social and professional reasons that induce men at or after middle life to attempt surgical work have been very active during the past ten or twelve years. If we search for an explanation it takes us beyond professional or ethical limits. It becomes a problem in sociology and shows a strange lack of discrimination on the part of those who have to select a surgeon. The readiness with which men and women, especially the latter, submit to operations is only equalled by their indifference concerning the fitness of the operator. It is all difficult to explain, unless it

may be an upheaval on the surface of the existing social order of a primordial civilization that held human life cheap. Our author teaches the young men and his skirts are free from the odium which, according to Dr. Kelsey, belongs to the postgraduate teacher. His responsibility, however, does not end with teaching surgery. The young graduate should be given a high standard of surgical attainment. He should be surgically trained as well as surgically taught.

Dr. Craig's contention that the operation is safe in trained hands fails as a criticism of my position that certain dangers belong to the operation *per se*, since he admits that perforation may occur to the most experienced operator. The only advantage that the man of experience would have over the surgical novice or general practitioner would result from the fact that he would know how to deal with it, while the other man would open the abdomen and attempt to sew up the uterine rent, which might be comparatively safe if he knew enough to let it alone. Further, a man may be a fairly safe ovariologist, hysterectomist, appendectomist, and yet make a veritable fool of himself when he attempts the dangerous operation of uterine curettement. This is the operation that belongs to the general practitioner and to the belated surgeon, and which he is encouraged to attempt by the textbooks for students and general practitioners, usually written by men in Dr. Craig's position, or by articles in the journals, so cheerfully optimistic in the interest of the inexperienced surgeon that the most serious complications are charged up to the trained surgeon on equal terms with the untrained. This is, to say the least, a dubious way to encourage the untrained surgeon to seek faithfully to do his best, with a due regard for human life. There was a time not so very many years ago when gynecic operations were done by the elect; then our author's criticism would hold good that it was not right "to characterize the operation of uterine curettement as dangerous in the abstract," from the standpoint of the operator at least. The abstract side of any question is hardly a safe one to generalize from, and is especially so here since this operation, as well as many others, is in the hands of the average and under-average men.

A great responsibility rests upon those who assume to teach. Is it safe, for instance, to state that the vagina may sterilize itself by its own secretions without also stating its corollary that this is true of the normal vagina with normal secretions only and that this immunity exists by such a narrow margin that it is negligible in practice. It would be more fair had the author given some later facts concerning this quality of

the vagina now fast becoming mythical. Döderlein in vaginal secretion found fifty per cent. of pathological bacteria, while ten per cent. contained *Streptococcus pyogenes*. Czerniewski demonstrated the presence of the same germ in thirty-three out of eighty-one women. Robb and Smith show that sixty-four per cent., all streptococcus cases, were found following labor or abortion; the very class of cases in which the average man would feel impelled to operate. In view of the interrogation in Dr. Craig's title he is writing for the general practitioner instead of the expert. From this standpoint I cannot forbear to express regret that our author indorses the irrigating curette. Dr. W. R. Prior's assertions of its possible dangers, backed up by actual demonstration, ought to condemn the instrument. If the question of method is ever to be settled, careful statements of facts from such a competent observer as Dr. Prior ought to be accepted as final, or at least deserves mention by the most opinionated writer. His statement makes it certain that there are dangers which inhere to the instrument aside from any question of skill on the part of the operator.

Another statement which is made too positively and which ought to be modified is, that if we have measured the depth of the uterus and introduce the dilator, I assume, to conform to this measurement, there is no danger of perforating the wall of the non-puerperal uterus. Why not say something about the time required and the force one may safely exert at this stage of the operation? As a matter of fact, I do not believe that rupture or perforation of the organ is made by driving the dilator too far within the cavity, but that it is due to the enormous force that can be exerted by the leverage of the expanding blades.

The day of writing for "those competent to undertake the performance of any surgical procedure" is past. The belated surgeon and the average man is an assiduous factor in American surgery and in elementary textbooks and journal articles he must be reckoned with. A man of Dr. Craig's reputation and position has grave responsibilities resting upon him. His utterances carry greater official weight than those of others not so placed. While he has safeguarded the operation with every precaution and made it as safe as it is possible at his hands, has he placed any danger signals out to guide the untrained man who attempts to carry out the details of his exquisite technique; or from this far more serious side, in what way has he driven the fact home to the "experienced" man that in making a uterine curettement he is dealing with a dangerous oper-

ation? We cannot lessen danger, nor change the fixed qualities of the personal equation by magnifying the value of technique.

Dr. Charles B. Kelsey, of New York, in a paper entitled the Surgery of the Day, in this *Journal* for January 2, 1904, takes my paper on The Dangerous Operation of Uterine Curettement, appearing in this *Journal* for October 10, 1903, as a text to explain some of the bad surgery of the day. My thanks are due to Dr. Kelsey for the pleasant allusion to my article, but I never regarded it as an omission on my part that I made no attempt to explain the existence of the unskilled surgeon. Dr. Kelsey, however, has convictions on the subject unalloyed with either doubts or fears.

The author traces the imperfect knowledge of the amateur surgeons of to-day to the postgraduate medical school. "There the surgery taught is good in itself and taught by masters, but it is taught to those incapable of understanding and with no restrictions upon their use of it." This may be true, but from what source did the postgraduate student gain the desire to become a gynecologist or take up any surgical specialty, usually at or past middle life? There was a seed thought, and I think the most reasonable place to look for the germ exists in the text book for the general practitioner. After that the postgraduate school, but not always. If all who attempt surgery would take the time to study the branch they have elected to follow for six weeks or so in some postgraduate school a better showing might be made. I am not one who believes that no knowledge is better than a little. I have seen so many examples of this class that I am satisfied with even a little knowledge in a special direction.

The men who swell the army of amateur surgeons are text book graduates. Nearly all of the men who were guilty of the deplorable accidents referred to in my paper were of this type. It is very evident that Dr. Kelsey, strenuous as he is in denouncing the class of men that the postgraduate schools scatter over the country to do their worst to humanity, has not sounded the depths of the evil. He has not said anything about the man himself. He is too impersonal, and by overlooking the man's incapacity for self-help, condemns the only agency that offers him any help at all.

The evil tendency of the surgery of the day cannot be understood without a study of the prime factor of the error, the man himself. He defines a type; the man who has passed his life in narrow surroundings and has reached or is past middle life. He has been a fairly successful general practitioner, but hardly ever of the highest grade.

Very often he is a man with a grievance and his ability and profound knowledge, of which he never tires of talking, have not received the appreciation they deserve. When he happens to be in a company where he cannot brag he is silent. In his county society, which he rarely attends, he never contributes a paper or joins in a debate; looking down upon his colleagues and holding their opinion as of little worth. He is a man of ambitions—the little, querulous aspirations that beset the ill trained mind. He believes that he is capable of higher things and his sense of duty well performed is always cramped by his morbid egotism. His normal habitat is in the small towns among the daisies, the elegiac flora of the village church yard. He is never a text book graduate, but he belongs to the kind upon whom Dr. Kelsey opened the phials of his wrath.

These men make a common mistake. The healthy man between forty-five and fifty-five years of age is in no manner conscious of age, nor need he be. He is simply at the summit of maturity; but he cannot reeducate the old centres of muscular coordination, nor can he forget one kind of training and educate his mind to think in terms of a new occupation. If I was to tell a belated surgeon that I intended to study the violin and become a great artist he would pronounce me a lunatic; and yet, he intends to do something more difficult and more hopelessly unattainable. If he was a genius he could not do it, for the genius has lived his life before he starts on his surgical career.

This man is aided and condoned by a strange social phenomenon peculiar to the American people. They take him at his own estimate of his ability and skill. Within a year he may make the claim, not without reason, that he is doing all of the surgery in his town. His chosen field is a narrow one. He removes tubes and ovaries with consistent indiscrimination, but his one hold, that excels in force "the power of herbs and might of magic spell," is appendicitis. In this field he is supreme, with a facility of diagnosis only equaled by the abiding faith of his public. He is the one who has run the death rate of appendectomy to the ghastly figure of thirty per cent. and held up American surgery as a spectacle for all the world. The trained and educated surgeon has an idea that the public will find him out and keep away from him. They do not find him out, for we are a peculiar people,—a people of fads, and the present surgical fad is appendicitis. Of course the fad will die when the time comes, and we shall look back on it with shame, just as we do to-day on female castration; but meanwhile he and his

type are working their malignant will about a disease upon which no man thinks sanely.

The surgeon estimates a man's fitness as a surgeon by the number of his recoveries, but the public has another standard which appears to be the number of his operations and his success in boasting of them. I know of one man who has the ability to achieve a very respectable death rate in repairing birth rents in the perineum and cervix, which is openly discussed in his community, without any impairment of a considerable practice. I trust that Dr. Kelsey will perceive that we have not only the postgraduate school graduate, but that we have a public prepared to receive and put faith in him. If we are going to find a remedy for this we must begin at the bottom and work up. While we have been advancing the cause of medical education we have neglected to educate the people in discrimination and good medical and surgical judgment. Until we do this the unfit and belated surgeon will do his share of work along with better men.

In the text book graduate we have another phase of the belated surgeon. He is the product of social conditions which have developed with great rapidity in a few years. Small towns and villages, with populations ranging from 1,500 to 5,000 inhabitants, have organized local hospitals. The women have raised the money and been foremost in erecting new buildings or in converting old ones to hospital use. They have done this out of the goodness of their hearts and from a most commendable philanthropy. But they have created in their midst an evil which is active in a ratio proportioned to their means of doing good. The best men of the town, as a rule, have been selected for the staff. Those who were the most popular have become surgeons, while others have received places on the medical side. In little hospitals of from five to fifteen beds every important surgical specialty is represented. With rare exceptions they are text book specialists at or past middle life. The most radical surgical methods are followed. Appendicitis is never given medical treatment. The infirmities of women afford ample scope for surgical intervention. The most difficult genitoplastic operations are undertaken with results not necessary to describe. When they are in doubt the textbook is brought into use and from which very singular procedures are undertaken. One of the best of these surgeons had a case of bladder incontinence which he treated by doing Emmet's buttonhole operation and afterwards found that he was unable to do the simple operation of closing it. This is only one illustration of what the text book will do for

the text book surgeon. The ophthalmologist, hitherto content to do his best in adjusting glasses, does iridectomy and operates for cataract, while the rhinologist finds ample recompense for belated opportunity in diverted septa.

If any one among our readers is familiar with these rural hospitals and believes that I have over-colored the picture, if he will take the trouble to state it I will submit cheerfully to the correction. I am simply giving my own experience of the work done, for many of the unfortunates drift afterwards into my own hands in the central New York region. I regret to say that I do not believe that the special surgery will ever improve, as there is not material enough to build up the expert, nor would it pay for a well qualified young man to locate in one of these small towns.

Dr. Kelsey's theory fails to explain the situation in the rural hospitals. These men are rarely the product of the postgraduate school. They do not resort to these schools, because they cannot afford it. After the appointment to the surgical side of a rural hospital the only way to hold it against all rivals is by showing the best front that he is able to. It would be a confession of weakness to seek knowledge for two months, or so, at a polyclinic. He is obliged to stand by his work and rely upon the text book. In spite of the fact that these rural institutions develop the belated surgeon with his undeveloped surgical judgment, his untrained diagnostic faculties, his uneducated touch, and his ignorance of technique, I believe that they do more good than harm. They are emergency hospitals in their true rôle. The country is traversed by railways and electric lines along country highways, while farming is carried on largely by machinery which inflicts serious injuries. All combine to produce a class of accidents unheard of ten years ago, and in the care of which the country doctor is most proficient. The men who cause all of us serious regret when they attempt difficult surgical specialties here show their shining qualities. Life is but a compromise and no evil exists without its alloy of good. The rural hospital is of such recent creation that it shows its worst side. The belated surgeon will pass and be replaced by younger men better educated who may be taught to let some things alone. His opportunities for harm will be less. The appendicitis fad like all other fads among us will pass. The respect shown by expert gynecologists for the intact female genitals, which exists already in fair proportion and is yet growing, will permeate the country side and do away with some scandals and much evil.

I think that Dr. Kelsey will agree with me that what he explains in such simple terms is really a

very complex matter. When we see errors it naturally causes us to look about for some means of correction. It is not the kind of morality which bears fruit that contents itself with finding fault. The Rooseveltian dogma is that there are not many removes in evil between the bad man and the impractical good man. What the medical profession now ask and the general public will soon strenuously demand is a remedy for the widely spread surgical incompetency that exists in the United States. As Dr. Kelsey truly says, we find here "some of the best and most of the worst surgery of the day." I believe that some of this bad surgery can be improved, not to equal the best, but to bring it to an average level of safety. "But of what use is it to record these things?" Dr. Kelsey asks, "unless a remedy can be found. They cannot be told to the laity without discrediting the whole profession, and telling them to the profession is useless—because they are already known." I take it that our first duty is to humanity and not to the profession. Our sense of humiliation comes, not from what the laity may know about our professional derelictions, but from what we know concerning them. So far as the laity is concerned are we not sufficiently discredited already? Appendicitis is the subject already of constant ridicule and humorous stories in the lay press, which state of mind on the part of the public will be sure to effect a remedy in time. The humiliation of this is that reform will be forced upon us from the side of the laity instead of the profession.

The same was true concerning the laws enacted for a State examination to practise. Had there not been back of it a general conviction of the necessity for the reform, it surely would have been defeated by the teaching medical bodies. Dr. Kelsey lays the responsibility for surgical unfitness to the shortcomings of the postgraduate school. He is partly right, but if he is going to correct the errors, he will be obliged to do so through the force of opinion created among the laity. I fail to see how the profession will be discredited by this. Discredit never came to an individual, or a class of individuals, by attempts to do better or to reform. On the contrary, it comes from sitting inertly under the morally debilitating conviction that a wrong to correct or a stain to wipe out lies at your very door.

There is something radically wrong in the surgical teaching of the day. The colleges teach surgical rudiments, not surgical art. They do not attempt to educate the surgical specialists. One of the best of medical colleges with a four years' curriculum gives to gynecology thirty-two didactic lectures and sixteen clinics in the fourth year.

It will barely enable the graduate to pass the State examination. General surgery fares a little better, as the work begins in the last half of the third year. The only chance the graduate has to supplement this is to secure a hospital position, which, to the great army of graduates, affords no relief. The polyclinics and the postgraduate schools were, it is only logical to conclude, founded to supply this want. This they cannot do. In the first place the courses in any given branch are too short to give a practical training. In the second place, they start out on the theory that they are dealing with educated men who simply need to brush up. Consequently they attempt to give in a few weeks what the colleges barely touch upon and of which the postgraduate student is ignorant unless he has been diligent with his text book.

The postgraduate schools are extralegal teaching bodies. They have charters which enable them to hold only property in which the object and purpose is stated after the usual formula in private charters. They have no legal status as teaching bodies and any credential they may grant is not recognized in law. In order to conform with the educational laws of the State of New York they should be under the restrictions of the Board of Regents, and until they do this they are violating the educational laws of the State.

To meet the conditions which have developed in the postgraduate schools additional legislation is needed, not aimed at these schools in particular, but controlling all schools in which after the conclusion of the stated course of study a final certificate of fitness and training is given. This credential is intended by the schools that grant it and by the student who receives it to have a certain value by inducing the public to have extra confidence in the holder in the business or branches covered by it. The holder of such a certificate should be required to pass a new State examination before he is allowed to seek special business in the calling covered by his certificate. The State medical examination is intended to test the fitness of a general practitioner, and it gives to the holder no extra fitness in any special subject. But in fairness to the State licentiate and to the public, when a man receives a credential of fitness in any special branch and intends to appeal to the public as one having more than ordinary knowledge and skill by reason of it, public safety demands that he should be subjected to a test of his extra attainments. An amended law to this effect would not effect the general practitioner in following any branch of his profession. It would only regulate the man who by an inadequate

course of study had acquired some written credential as a specialist and which he intended to display to the public as evidence of his special attainment.

If, however, the postgraduate schools were to pass under the control of the Board of Regents and the certificates of attendance emanate from that body nothing more would be needed to make such a certificate well worth seeking. Looking back over the profession as I have seen it, there is every reason to be optimistic as to the future. Young men of a higher grade are entering the profession; better educated and specially fitted to study medicine. They will bring greater knowledge, better trained faculties, and a refined capacity for discrimination and judgment to their life work. This higher grade man will also educate his public, which is already beginning to see that the tail of the plow is a poor preparatory school for the study of a profession that is yearly becoming more difficult. The present type of man that has gone daft in his surgical furor will have no standing then. Let us hope for better things. Let all of us, who have suffered many things and have been made desolate at the hands of these men, hope that they who come after us will receive the ministration of trained hands and sane minds.

MALPOSITION OF THE ABDOMINAL VISCERA, AND MEDICAL AND SURGICAL TREATMENT FOR SOME OF THE ACUTE CASES.*

By G. E. BENNINGHOFF, M. D.,

BRADFORD, PA.

During fifteen years of surgical work, a greater portion of which has been abdominal operations, many of them necessitating a free opening of the peritoneal cavity, I have so frequently observed displacement of one or more, or all of the viscera, that I am compelled to believe the condition of vast importance, not only to the surgeon, but to the general practitioner. When one considers the very important place that regional anatomy holds in physical diagnosis, it is not difficult to understand the necessity of knowing the relation between normal and displaced organs.

Allow me to say that I have frequently found displacement of every organ contained within the abdominal and pelvic cavity, in some, one particular organ, others, another organ, and yet again, several, and in many, all; in fact, general splanchnoptosis obtains quite as frequently as displacement of one or more of the organs. This can be accounted for by the fact that in general splanchnoptosis there exists a complete relaxation, while

* Read before the meeting of the McKean County Medical Society, at Bradford, Pa., May 3, 1904.

in displacement the displaced organ usually depends upon either pathological conditions present in the organ displaced, or in adjacent organs, or in supports; therefore, all pathological conditions affecting the neurotic tone of the system may produce the former, and when one considers the vast amount of exhausting, debilitating, and wasting diseases, one can see how very common must be splanchnoptosis, of some degree at least. But displacement of certain organs not due to splanchnoptosis is the condition which, because of the absence of general relaxation, is the most frequently overlooked by the diagnostician. Malposition of some organ, not due to splanchnoptosis, occurs so frequently that one is often at a loss to know what causes it, even while operating. As to my own observations, enteric displacements are those most frequently present, and displacements of the colon, the transverse colon particularly, are the most common of any in the abdominal viscera, and one can readily understand that if the transverse colon is tossed or displaced the ascending and descending colon, as well as the cæcum and sigmoid flexure, must necessarily be in an abnormal position; hence, due to angularity, we may have constipation, appendicitis, fecal impaction, and ileus as results.

The great number of times that the appendix is found displaced to a greater or less degree indicates how frequently the cæcum must be displaced, and, therefore, the relative position of the colon. The appendicular organ has been found at almost every possible locality within the abdominal and pelvic cavity, and I have found it twice outside, once in the right femoral canal, once in the left scrotum, both times, however, with intestinal hernia. I have dissected it twice from the lower side of the liver close to the gall bladder, and quite a number of times I have found it on the left side of the median line. In fact, one should always consider the possibility of disease of the appendix when other symptoms exist with some particular sore point within the abdominal or pelvic cavity, as well as an accompaniment of hernia protruding through or within any of the openings from the abdominal or pelvic cavity. Therefore, displacement of the cæcum must be very frequent and the range of mobility very great.

If not too trying on your patience, I should like to report the case of appendicitis in the femoral canal, also that of the left scrotum. The ordeal will be very brief. In the month of October, 1886 (when little was known regarding appendicitis), I was called to operate on a strangulated femoral hernia in a lady, aged 28 years. There was the usual enlargement in the right femoral canal, but

the extreme soreness to touch and elevated temperature of 103.4° suggested something more than strangulation, which had been present less than twelve hours, without obstruction of the bowels. However, the usual incision was made when there appeared in plain view a gangrenous something of which (never having seen a gangrenous appendix) I was very suspicious, but after removing it, and while doing so finding it attached to the bowel, I concluded it was the appendix. That was my first appendectomy; of this I am sure, for it was my good fortune to open this same abdominal cavity five years later for a subserous fibroid, and ten years later for a pyosalpinx. I found the appendix absent at the second operation, and it was still absent at the third. The lady since her last operation, in 1896, has been in perfect health, and undoubtedly the appendix remains absent, as she has not been operated on for appendicitis in the mean time.

The other case was in a baby of 11 months, operated on in 1901, who had acute strangulated inguinal hernia of the left scrotum during an attack of bronchial pneumonia. The strangulation was complete; and because of the pneumonia the little one was in extremis. The usual incision was made, which, when the sac was incised, revealed the head of the cæcum and attached to it the appendix, which was sloughing. The bowel was badly discolored, but was returned with the hope that it might resolve, which it did. The babe recovered.

Enteroptosis of the small intestines I have found quite a number of times and twice, I am sure, death would have resulted very quickly if the conditions had not been remedied. Because of surgical treatment being followed with success in the two, and medical treatment successfully in some others, I wish to describe these cases.

November 27, 1902, I was called to see Miss O., aged 34 years, slight of stature, in consultation with Dr. J. H. Robison. Miss O. gave the following history: Had been ill for three days, bowels had moved from cathartics, and for two days she had had some nausea. Dr. Robison was called the morning of the day I saw her, and was fearful of intestinal obstruction because of extreme nausea, vomiting, pain in the lower abdomen. When I saw her at 11 o'clock p. m., I found her almost pulseless, body and face covered with a cold, clammy sweat, anxious expression, constant vomiting, which was stercoraceous. Operation was decided upon. She was taken to the hospital and was immediately operated on. When the abdomen was opened through the linea alba, the transverse colon presented immediately above the pubes, so low down that at first sight it suggested a full bladder. Further examination revealed the fact that all of the small intestines, ex-

cept the duodenum and jejunum, were impacted within the pelvic cavity. With considerable difficulty the intestines were lifted up into normal position, when they were found very much congested and discolored. The circulation returning to them, however, soon gave them a nearly normal color. There was no disease of the appendix, tubes, or ovaries, and the patient recovered without one unpleasant symptom. I am fully convinced this patient would not have lived until the next morning. Dr. Robison and Dr. Hogan, who assisted at the operation, both think as I do. I am not aware of any similar case having been previously reported. The case was one of intestinal obstruction due to impaction of the ileum within the pelvic cavity.

Before giving a synopsis of a case of enteropneumosis which recovered under medical treatment, allow me to state that much has to be taken in doubt, as far as diagnosis is concerned, and because of the fact that surgical interference made the diagnosis in the other case, I shall endeavor, in this case, to state the few principal symptoms which I have observed.

Miss B., a maiden lady, aged 44 years, was taken ill December 8, 1903. Her previous history is that of a nervous dyspeptic, with considerable difficulty in getting the bowels to move at certain times, and always constipated. She had several attacks of acute stomach trouble, but did not call a physician. However, this time, because of continued nausea and vomiting, she called Dr. D. E. Ash, December 9th. He prescribed the usual remedies for nausea and vomiting, also a cathartic, which was repeated on the 10th and 11th. Nausea and vomiting continued, getting worse each day. The vomit had become fecal and black. Rectal enemas of Noble's solution, etc., had brought away, December 11th, a dark liquid, but increased the nausea and vomiting. I was called the evening of December 11th, as patient was greatly depressed. Examination showed a well developed woman, musculature of limbs and trunk good, skin moist, patient dull, expression passive, tongue voluminous, indented, and coated, breath foul; patient very nervous, and moaning with nausea; pulse 128, small and soft, temperature 98°, urine not sufficient, but not measured or examined. The abdomen above the umbilicus was retracted and bulging two inches below. By gently stroking with the warmed open hand from the stomach downward, the transverse colon could be distinctly located two inches below umbilicus. Below this was a flat surface, extending across abdomen, about two inches wide. The ascending and descending colon could also be mapped out distinctly, and both the hepatic and splenic flexures were too low. There was no tympany except in the colon. The abdominal musculature was good, yet I diagnosed enteropneumosis. The nausea, vomiting, obstipation, absence of pain, malposition of entire colon, absence of normal amount of intestines in abdominal cavity, no elevation of temperature, in addition to a soft and flabby mass in pelvis, as shown by digi-

tal examination, were the symptoms from which I made the diagnosis.

Now as to medical treatment in these cases, I think that the patients on whom I operated, if treated medically soon enough (or, I should say, mechanically, for drugs are of little use), would have recovered without an operation, as this one did, but treatment must be begun before the displaced bowel, impacted as it is, becomes adherent, or glued one coil to the other, as in the case in which I report operation. In the latter case impaction had not occurred.

As I stated a moment since, drugs have little effect in these cases, even rectal enemas are insufficient until the intestines are replaced. How are we to accomplish this? I think posture alone will do it in a great majority of cases, as I said before, if begun early enough, and that means as soon as the case is seen, which may be too late. If pain and tenderness in the lower abdomen have developed, with an elevated temperature taken per rectum, I think it is an immediate surgical case. In the second case, the bed was elevated to a modified Trendelenburg position, about 30° (Trendelenburg's is 45°), and so remained during the night. There, was some flatus passed about five hours after adopting the position. The next morning a high enema brought away a large evacuation of dark fecal matter and an abundance of flatus. After being placed in this posture, the colon at first changed but little, but in the morning it was five inches higher, while in the normal dorsal position, and the flat place below the umbilicus was now round and normal. The patient finally recovered.

The following case is interesting because of the fact that it exemplifies three conditions: splanchnoptosis, results of cured, recurring, appendicitis, and pelvic impaction of the small intestines:

Miss O., aged 30 years, school teacher, slender form, poor musculature, called me February 1st at one o'clock p. m. She was taken ill the morning of the same day with nausea and vomiting, which through the forenoon had increased. She had had several previous attacks, usually with severe pain in right iliac region, and had been in bed with three or four such for two or three weeks each time. Her symptoms when I first saw her were extreme nausea, vomiting every few minutes, pulse 120, temperature 97.6°. She was alone in a boarding house, and I left her to return a few hours later. By this time, 6 o'clock p. m., she was in extremis, every symptom having grown worse. She had not had pain during this attack. I advised immediate operation, which was done at 10 o'clock p. m. (this time being consumed in getting her to the hospital and preparing her), as her condition was bad, and to delay while try-

ing other treatment might have placed her beyond even surgical help; besides, she gave a history of repeated attacks of appendicitis. The operation proved how dangerous delay would have been, and also the fact that, although the entire ileum was impacted within the pelvic cavity because of adhesion extending from the cæcum to the parietes, partially strangulating the intestine, posture would have failed to have saved her life. The usual incision was made for appendicitis, and the first viscus that presented was the pyloric end of the stomach. The right lobe of the liver and the gall bladder could readily be felt about three inches above the upper end of incision. The transverse colon was tossed and the ascending colon and cæcum were very much too low. After incising the adhesions, the small intestines were raised from the pelvic cavity, and about three feet were found to be badly discolored. However, after raising the parts, the circulation returned, and I felt safe in allowing them to remain. The appendix was a mere thread, and had it not been for the mesoappendix, one would not have found it. It was beyond any danger of disease, but the adhesions left resulted in a greater immediate danger than would an acute attack of appendicitis. Generally these patients are in such an extreme condition that any radical operation to cure the enteroptosis cannot be done. This patient was placed in the modified Trendelenburg position, and kept so for five days. She made a good recovery from the acute condition, and was advised to stop teaching school and take long walks, physical exercise, etc., to tone up the musculature.

Posture in the treatment of diseased conditions, either medical or surgical, has long been neglected, but of late it has received some attention. Dr. Fowler, who advocates the jackknife position for inflammation of the lower abdominal and pelvic cavity, states that this localizes the inflamed part and walls it off from the general cavity. Some one, whose name I have forgotten, advocates the opposite, having the upper abdominal cavity the lowest point, because of the greater amount of glands to absorb disease germs. If one takes into account the influence that posture has on the blood pressure of the part inflamed, and which posture will furnish the most leucocytes to the part, I think he can select well that which is best. Frequently we find the abdominal cavity quite filled with fluid, which consists of lymphoid phagocytes. It might be well to use a posture which would cause this fluid to gravitate to the septic parts.

Since writing the above, I may add two cases of enteroptosis cured by posture.

CASE I.—Miss D., 30 years old, was taken sick about January 1st with severe pains in right iliac region, the tenderness extreme at McBurney's point, temperature normal by mouth and 99.5° per rectum, continuous nausea with frequent vom-

iting. Diagnosis, appendicitis; operation refused. On second, third, and fourth day nausea increased, abdominal muscles both sides tense, no elevation of temperature, colon plainly visible below umbilicus, pelvic contents doughy, bowels not moving. High enemas had been tried for three days without any result, but the morning after elevating foot of bed, one was given which had the desired result, and patient made quick recovery.

The last case which I have to recite is such as the surgeon frequently sees. The patient was operated upon in January 14th by an out of town surgeon at the Bradford Hospital. The uterus was suspended, which was the only abdominal work done, yet every means usually employed failed to evacuate the bowels. The patient was nauseated constantly and was vomiting very frequently. Her physician telephoned the surgeon of her condition, and he thought there must be some obstruction, and considered it best to reopen the abdominal cavity. Her attending physician, Dr. W. J. Russell, stated the case to me, as patient's former surgeon could not come to operate. Knowing the patient's relaxed condition well from a recent examination, I suggested the modified Trendelenburg position at 10.30 p. m. The bowels were evacuated thoroughly at 3.30 p. m., and the patient is now rapidly recovering.

It is not alone the posture of which I have been speaking that is useful. The genupectoral is good for immediate action and replacement. Again, in acute inflammatory conditions, such as pelvic peritonitis or appendicitis, Fowler's posture, in which the shoulders and head are raised and thighs flexed on body, is indicated because of the tendency of this posture to localize the inflammation. This is done by the walling off process, aided by the serous fluid, which consists principally of lymphoid phagocytes, and this great reinforcement of fresh troops, as it were, has a disastrous effect on the pathogenic bacteria. In appendicitis, either because of refusal to operate, or because the best time to operate (thirty hours) has passed before the physician sees the case, I would suggest a modified Fowler's posture, that of inclining the body and pelvis to the right side so that the appendical region would be the most dependent.

Thus far I have dealt with only two or three of the abdominal viscera which may have malpositions, and have dealt with these not in detail, but superficially. I have not mentioned malpositions of the stomach, kidney, liver, gall bladder, or any of the pelvic organs, urinary bladder, or ureters. I may say, in considering these conditions as elsewhere, What should be the posture in the treatment of acute septic cholecystitis, i. e., what posture is best to evacuate the gall bladder? Even in cases of stone in the cystic or common duct, posture might help

greatly to dislodge the calculus. Posture during digestion in gastroptosis might be very useful in allowing the contents of the stomach to pass through the pylorus. Am I venturing too far when I say that one particular posture is the best in all diseased conditions of either the organs of the abdominal cavity, thoracic organs, brain, or any of the extremities? In acute tuberculosis of one lung, in pneumonia, pleuritis, pericarditis, one posture must be better than any other. Let us use our best judgment to decide what really is the best posture. I hope some of my medical friends may take up this subject and give us further light.

From what I have said, I do not wish to be understood as championing any treatment for these desperate cases, except that of prompt surgical interference when that can be done, but usually the surgeon does not see the patient for several hours after the conditions have begun, and very frequently, too frequently, several hours after the attending physician has been called. What I wish to state is the possibility of curing the conditions before the surgeon comes, and in case of refusal to allow an operation, to suggest posture as a means of cure. Again, the diagnosis is of vast importance, both to the attending physician and surgeon. Posture in postoperative cases is of great value. By no other method can adhesions, when not wished for, be as well prevented. In extensive pelvic work, it is next to impossible for the surgeon to cover over all denuded parts, because, first, he has not the peritonæum with which to do so, and, second, time is too valuable in these frightful cases to waste it in endless stitching. The modified Trendelenburg posture will allow the intestines to gravitate to the upper abdominal cavity, and if continued for three or four days, they will not adhere when coming again in contact with the denuded parts. Postoperative posture is frequently just as valuable to fasten by adhesion displaced viscera, as is well known. Finally, allow me to say that since I have observed the great benefit of posture, and have so frequently had recourse to it, I do not hesitate to make the statement that the modified Trendelenburg posture is the most positive means that the surgeon has at his command to control postoperative nausea and vomiting. Eight to twenty-four hours in this posture will, in ninety-five per cent. of abdominal sections, prevent this terrible suffering and exhaustion, and usually in twelve hours the patients are retaining whatever fluid they wish, which, of course, is usually cold water, and which they need badly enough. It is really surprising how differently they appear

and feel, as compared with the usual nauseated and vomiting patients that I have had to witness for the past fifteen years, as they lay in the flat, dorsal position. In the Trendelenburg posture gastric hæmorrhage has not occurred, and the promptness with which it controls the vomiting would seem to make it a preventive of that condition rather than a cause.

A CASE OF EXTREME SEPSIS FROM MULTIPLE SINUSITIS, WITH DESCRIPTION OF OPERATION.*

By WILLIAM W. CARTER, A. M., M. D.

NEW YORK,

ASSISTANT SURGEON, MANHATTAN EYE, EAR, AND THROAT HOSPITAL.

The following case which came under my observation in Dr. Knight's Clinic at the Manhattan Eye, Ear, and Throat Hospital embraced features so unique, and showed so clearly the general effects of a severe sepsis, having its focus in the sinuses accessory to the nose, that I considered it worthy of being presented for your consideration.

A. M., female, aged 22 years, presented herself for treatment at the Manhattan Eye, Ear, and Throat Hospital in September, 1903. She denied specific history, and said she had been perfectly healthy up to four years before, when she had the grippe; following this she had an almost continuous discharge of pus from the nose for two years, when the right side got well and the trouble was confined to the left side.

Occasionally the discharge would almost stop for two or three days, at which times the left cheek would become swollen and painful and the conjunctiva of the left eye injected; these attacks were always relieved after a large amount of foetid pus had escaped. Patient's general condition was only fair, but her intellect was extremely dull.

At times she suffered with severe occipital and vertical headaches. She had suffered for some time with attacks of facial neuralgia on the left side. She attributed these attacks to a decayed upper molar; this had been extracted without affording relief.

Examination showed pus flowing from the left middle meatus, and polypoid degeneration of the middle turbinate. By posterior rhinoscopy, pus could be seen flowing over the end of the inferior turbinate, and down into the pharynx. Transillumination showed the left antrum to be opaque; the frontal sinuses by this test appeared to be normal.

I removed a portion of the middle turbinate, enlarged the ostium maxillare, and practised irrigation with boric acid solution for two weeks, but as there was no improvement I decided to do a radical operation; so on November 28, 1903, a broad opening was made into the antrum through the canine fossa. This cavity was found filled

* This case was reported at a meeting of the Laryngological Section of the Academy of Medicine. Paper read before the Society at Alumni of Bellevue Hospital.

with pus and the walls covered with granulation tissue, which was scraped away. The inferior turbinate and the inner wall of the antrum down to the floor were removed; the mucous membrane on the nasal side being preserved by introducing the little finger of the left hand into the nostril as a guide, and picking off the spicules of bone with thumb forceps through the maxillary opening. This flap of mucous membrane was afterwards divided and reflected into the antrum, thus furnishing a lining of healthy mucous membrane for a greater part of this cavity.

Recovery from the operation was good, and the case seemed to be progressing satisfactorily until the third day, when the patient began to complain of pain in both knees and the right wrist; these joints became swollen, slightly inflamed, and very sensitive to the touch, but on aspiration were found to contain no fluid. The legs were slightly swollen and oedematous. These articular symptoms did not correspond to those of acute articular rheumatism; there were no acid sweats, no hyperacidity of the urine, and there was no tendency of the inflammation to subside in one joint, while developing with increased severity in another; but all were affected together. None of the complications so frequent in rheumatism were present. She complained also of severe occipital headache and stiffness of the neck. On both cheeks there was a bright hectic flush, more pronounced and attended by some swelling on the affected side. The temperature had a diurnal fluctuation between 99° and 103° F. The tongue was dry and brown, the stomach extremely irritable, and the bowels loose. The vaginal secretion contained no gonococci, the blood examination showed moderate leucocytosis. The urine, which previously had been normal, now contained a small amount of albumin and epithelial and hyaline casts. She was passing only twenty ounces in twenty-four hours, and the amount of urea excreted was much diminished. The condition of the antrum appeared to be satisfactory, but it was evident that the posterior ethmoid cells and possibly the sphenoid were infected, as there was an abundant flow of pus from this region. At this juncture the symptom complex presented by sepsis, nephritis, and multiple arthritis was most bewildering, and it was some time before the relative importance and significance of each of these could be determined. These conditions persisted for about three weeks, during which there was a rapid loss of strength and emaciation became extreme. Then there was a slight amelioration of all the symptoms, and the patient was fairly comfortable for about two weeks, when suddenly on January 5th, five weeks after the operation, a marked exacerbation of all the symptoms occurred; the pain in the shoulders, elbows, wrists, fingers, knees, and ankles was so great that the patient could not move, the articulations of the jaw also were involved. She complained of pain in the left eye, the occiput, and stiffness of the neck, the eyeball appeared to protrude somewhat and the conjunctiva was congested. Mental dulness was increased; when asked a question fully a minute would elapse before the patient realized its sig-

nificance and the answer showed tardy, rather than inaccurate cerebration. The ophthalmoscopic examination showed a normal retina. Urinary symptoms remained unchanged.

On January 9th the patient had a violent chill, the temperature jumped to 106.4° F., pulse 150, and she became unconscious. There were retention of urine, incontinence of feces, and every appearance of profound collapse and impending death. Under vigorous stimulation, including the injection of three pints of normal saline solution into the median basilic vein, the patient rallied. A stimulating and tonic treatment was instituted, and with slightly ameliorated symptoms she gained somewhat in strength. She was now passing 35 ounces of urine, which contained albumin and casts.

On January 23rd, about two months after the last operation, it was thought that she could stand the shock of a radical operation upon the remaining ethmoid cells and the sphenoid, for there was no doubt that here was the focus of infection.

Having slight hope for her recovery on account of her extreme exhaustion and the condition of her kidneys, I operated on her in a manner first suggested by Jansen. Dr. T. Passmore Berens, of New York, has done much to perfect the technique of this operation and has reported a series of cases successfully operated in by this method.

In this operation the ethmoid cells and the sphenoid are approached through the antrum of Highmore, and the diseased area is removed with the bone curette working in cooperation with the little finger of the left hand introduced into the corresponding nasal cavity and acting as a guide. This operation is especially indicated where the antrum as well as the sphenoid is involved. However, it is also applicable where the antrum is in a healthy condition, for when the operation on the ethmoid cells is done entirely through the nose in a thorough manner the antrum is opened, for the ethmoid cells form part of the roof of this cavity.

The distinct advantages to be gained by choosing the maxillary route are:

(1) The operation can be conducted with much greater ease, thoroughness, and safety to the important adjacent structures.

(2) Hemorrhage is more readily controlled, especially if it comes from an injured sphenopalatine artery, as this has to be clamped. (This artery runs across the face of the sphenoid and is very liable to injury. Hemorrhage from this usually cannot be stopped by adrenalin).

(3) The drainage is much better.

(4) We can inspect the wound more easily during the process of repair.

I have performed this operation on several occasions where the chronic discharge of pus from infected and diseased sinuses was interfering more or less seriously with the health and comfort of the patient, and in each instance distinct relief or cure was effected. But on this occasion, where the *life* of the patient was the chief issue at stake, the advantages of the procedure are

much more distinctly emphasized, especially since the patient's long stay in the hospital had afforded ample opportunity to test every other means of relief. I regard the operation with such favor that I think a detailed account of it as performed in this case will not be amiss.

The patient was given gas-ether anæsthesia, the mouth gag was placed on the right side and the choana of the left side was closed by a post-nasal tampon. A stout silk ligature was then passed through the tongue near the tip, to be used in holding it forward during the operation, and a gauze pad placed between the cheek and the junction of the jaws on the affected side, to prevent blood from flowing back into the pharynx. An assistant having drawn the cheek over as far as possible with a blunt retractor, I made an incision through the mucous membrane and periosteum, parallel to and just below the attachment of the cheek, and reaching from the posterior extremity of the alveolus to the anterior border of the canine fossa. The periosteum was then elevated with a periosteotome over the entire anterolateral wall of the antrum, and to within an eighth of an inch of the infra-orbital canal. With a rongeur this area was then resected, the fibrous tissue being first removed from the opening in the bone made at the first operation.

The mucous membrane of the antrum was found in a fairly normal condition, and this cavity was being well drained into the nose through the opening previously made. Using the attachment of the middle turbinate as my guide I curetted away the anterior and posterior ethmoid cells, which were necrotic and filled with pus and granulation tissue. All blood, pus, and necrotic tissue were carefully wiped away, and the field made bloodless by packing the cavity with gauze soaked in adrenalin solution 1 to 1,000. The opening into the sphenoid could now be clearly seen; a posterior ethmoid cell opening directly into it the anterior wall of this cavity was removed down to the floor, it was necrotic and yielded readily to the curette. This sinus was also filled with pus and granulation tissue. After washing away all debris and again packing the cavity with adrenalin gauze to stop the capillary oozing, I could readily inspect the entire operative field. I then smoothed down the rough spicules of bone, washed out the cavity with normal saline solution, and inserted a wick of iodoform gauze into the sphenoid and packed the remainder of the wound lightly with the same material. The operation consumed one hour and ten minutes.

When removed from the table, the patient was in a precarious condition, but she rallied after the injection of three pints of normal salt solution into the median basilic vein. After forty-eight hours the gauze was removed and the wound irrigated with sterile soda-salt solution; this was repeated twice a day for the first ten days, when the irrigations were continued through the nose and the external wound permitted to close, which it did in a very short time.

Following the operation there was a gradual improvement in all the symptoms, and the patient

entered upon a period of convalescence, interrupted only by slight rises in temperature, and was discharged from the hospital February 17th, twenty-five days after the operation. At this time the joints were still quite stiff and the legs were œdematous. She was passing a normal amount of urine, which contained a few casts, but no albumin.

Since this time I have seen the patient repeatedly, and each time she showed some improvement. On one occasion I removed an ethmoid cell that had been overlooked at the time of the operation, and on two occasions removed with the snare an excess of granulation tissue that had formed in the region of the sphenoid. The last time I saw her, several months after the operation, she was feeling very comfortable and had gained greatly in flesh and strength. The urine was normal.

The points I wish to emphasize are:

First. The difficulty in making a diagnosis when the symptom-complex *may* be a result of sepsis, nephritis, and multiple arthritis.

Second. The seemingly entire dependence of all the symptoms on the sinus infection, and their prompt relief after operation.

Third. The efficiency of the maxillary route when dealing with infections in this area, especially when the antrum itself is involved.

69 WEST FIFTIETH STREET.

THE DIAGNOSIS OF CHICKENPOX.

By WILLIAM L. SOMERSET, M. D.,

NEW YORK.

Varicella, appreciating apparently its clinical insignificance, tries from time to time to maintain dignity and inspire respect by passing itself off for modified smallpox. It is reasonable to suppose that these attempts are partly prompted, also, by the indignity of the diminutive. The name, varicella, may have been all right when variola was at its best, a hundred years ago; at the present time it is a misnomer. Chickenpox can give a much more variously and numerous spotted condition of the skin than is found in many cases of smallpox. Far preferable is the beautifully descriptive synonym, *crystalli*, for the crystal clear vesicle is the most characteristic lesion.

The positive diagnosis of any of the exanthemata must be made from the eruption. This is especially true of chickenpox, for all other symptoms are very variable. There may be, in adults, intense backache and high fever during invasion, or there may be in any case practically no constitutional disturbance. The eruption, however, presents in character of individual lesions and in distribution, certain constants, without the presence of which, or the evidence of such presence formerly, the diagnosis must not be made.

The lesions appear first and are most numerous on the trunk. They are in their initial stage macules, but the macular period of any individual lesion is very brief. One must hurry to reach a case before some vesicles have put in an appearance. Here, as in smallpox, exudation begins as soon as the lesion appears. In smallpox, the exudate is sufficiently deeply seated to require a day or two to form a vesicle; in chickenpox, as many hours suffice. The chickenpox vesicle varies in size and color; in size, from that of a pin head to a split pea; in color, from clear and transparent to pearl gray and opaque, according to the proportion of the exudative products. A smallpox vesicle undergoes umbilication during its progressive development. Exudation is still going on and obliterates the umbilicus in the pustular stage. The chickenpox lesion, during the entire time of its advancement, is convex, rounded out, full. In its retrograde stage, due to either rupture or dessication, the top of the bleb becomes flattened or even depressed. Such a condition is readily distinguishable by sight or touch. Having in most situations a very thin epidermal covering (so thin, indeed, that it is scarcely appreciable to the eye), the vesicle of varicella is easily ruptured—very slight pressure from hands or clothing being sufficient. It results from this condition that a case almost from the first presents many broken down lesions. These lesions are then sores, open to infection from without, and many of them go on to the formation of pus, which will frequently be found forming a white ring around the depressed scab. Unruptured lesions containing purulent exudate occur in severe cases. They are always relatively few in number.

Where the epidermis is thickened, as on palms and soles—both of which varicella frequently invades—the exudate may be unable to raise a blister. The lesions in such situations remain deeply seated and are indistinguishable from correspondingly placed lesions of smallpox. The rest of the eruption must be taken into consideration. Briefly, then, varicella, seen early in its course, presents many clear, convex, fully rounded out blebs; seen late, many of these will be found ruptured, probably pustular, and surrounded by quite extensive areolæ, due to infection from without. It is, perhaps, worth remembering that a chickenpox vesicle may be drained empty through a single pin prick.

The distribution of the lesions is also distinctive. They are always discrete; never being sufficiently numerous to produce a confluent eruption. On the other hand, their number is seldom, if

ever, reduced to three or four. If such cases do occur, these few will surely be found on the trunk. Any case presenting a few lesions on the face, or on the extremities, and nothing elsewhere, is not varicella. In any case of this disease, be the lesions few or many, there will be more lesions on the trunk than elsewhere. In any case of variola, with a discrete or confluent eruption, there will be more lesions on the face than on any other equivalent area; except in those few, but undoubted, cases in which the whole number of lesions is, say, a half dozen or less. These three or four lesions may occur anywhere, segregated or far apart. It is said that the eruption of chickenpox appears in successive crops and that lesions, drying down, in full development, and just appearing, may be found side by side. This is true, but smallpox may present the same conditions—with this difference, however: in smallpox, such grouping may be found in one place, or in two, or three, places; in chickenpox, it may be found on almost any small area where the eruption is abundant. In general, in varicella the lesions are oldest, appeared first, and nearest together on the trunk; in variola, on the face. In varicella, they become further and further apart, as you pass downward on the extremities, so that, save in severe cases, the palms and soles show none; in variola, hands and feet are as freely invaded as elsewhere, the face excepted. There are said to have been cases of varicella in which the lesions were deeply seated throughout, did not break down, showed no marked preference for the trunk, and, almost uniformly, went on to pustulation. I do not believe that such cases would be inconvenienced at all by vaccination.

Between the mildest cases of discrete variola and malignant cases, there is no clinical resemblance whatever, their only bond being that each can produce the other in a person of requisite susceptibility. Cases of varicella, on the other hand, aside from variations in severity—that is, in the "abundance" of the eruption—conform very closely to each other. Any case giving rise to uncertainty should be isolated, as the chances are it is not varicella.

I have said nothing concerning faucial lesions. Both diseases give them small, rounded, white spots, or superficial ulcers. They are indeterminate in this connection. Concerning scars, their distribution must guide us. In chickenpox, aside from the results of outside infection, they are chiefly a matter of discoloration, and temporary. In smallpox, also, the scars may be superficial and temporary.

The foregoing remarks will be found, I think,

a sufficient guide for the differentiation of varicella from diseases of the skin. The one important thing is to avoid the serious and embarrassing mistake of confusing chickenpox with varicella. Such a mistake is a two edged affair, and cuts with about equal sharpness in both directions.

83 LEXINGTON AVENUE.

MENTAL WARDS IN GENERAL HOSPITALS.*

By J. MONTGOMERY MOSHER, M. D.,

ALBANY, N. Y.,

ATTENDING SPECIALIST IN MENTAL DISEASES, ALBANY HOSPITAL.

Considerable attention has been aroused in the step recently taken by the Albany Hospital in making special provision for patients afflicted with mental disorders, which is generally regarded as a departure from existing methods. The plan is not a new one, however, and it is a matter of some moment that the petition for the first American hospital, the Pennsylvania Hospital, was based upon the needs of "Lunatics or Persons distempered in Mind and deprived of their rational Faculties." This was in 1751, and insane patients were treated in the buildings with the sick and injured until 1841, when a separate department under an independent executive was created at a distance. This plan of distinct branches is also followed to the present day in the two existing colonial institutions, the New York Hospital and the Massachusetts General Hospital.

The reasons for the removal of mental cases from the others are not at hand. The attack of mental disease is more prolonged, and not infrequently the acute condition is followed by a defect which necessitates custodial care. The shortening of a broken limb, or the contraction of an inflamed lung does not prohibit the patient's return to his home and the community as does the residual blot upon the brain. We may assume that the accumulation of unrecovered patients probably proved an embarrassment, and the writings of Benjamin Rush bear out the belief that much of the work of the hospital was with chronics.

It is not necessary to review the lessons of the ensuing century and a half in the care of the insane. At the end of this period we are again confronted by a demand upon the general hospital for service in this branch of medicine. The function of urban general hospitals is now the treatment of acute disease. The question arises as to whether there should be any limitations of this duty; that

is, as to whether certain forms of disease should be denied admission. For large cities with numerous hospitals it may be expedient to specialize, and to designate different acute diseases to different hospitals. In smaller cities, of populations varying from fifty thousand to one hundred and fifty thousand, or two hundred thousand, the two or three good hospitals represent the purpose of the members of the community to secure for themselves proper treatment when sick or injured. The contribution of each individual, whether through public or private channels, is his measure of protection for himself or for some one near and dear. If the calamity which sends him to this institution for help is mental in character, he might demand, and he would be justified in demanding, that he be not spurned, when his neighbor with a surgical lesion or an infectious disease, has at his disposal every means known to science for the restoration of his health.

Some such thought as this led to the establishment at the Albany Hospital of a pavilion for mental diseases. The Albany Hospital was opened in 1849 in a building previously used as a jail. In 1898 this time worn plant was abandoned for a new institution on the outskirts of the city, consisting of a series of buildings connected by corridors. An opportunity presented for the construction of an additional pavilion for mental diseases. The physicians of the city and neighboring cities and towns of the county were anxious that this addition should be made, and warmly advocated the plan. Their feelings had been sharply stimulated by the deaths of two of their number in the county jail, in which they had been placed, from mental disorder. The only provision for public cases of insanity was in the State hospital at Poughkeepsie, seventy-five miles away, and every practising physician had been under the disagreeable necessity of transferring mental cases to this distant institution, under the delays of legal procedures, when he knew that prompt and proper treatment under a simpler plan for a few days or a few weeks would result in recovery. It was an operation of necessity, and not of election. Applications for the admission of patients to the new wards were received before the building was completed. The situation at Albany was identical with that of other localities in the State.

It is of greatest importance that the patient should be taken from the situation in which the disease originated and sent to a place specially arranged for his care. If that place is in the city where the patient resides, and under the care of a physician well known in the community, much of the unwillingness to leave the home will disappear. Even when greatly excited or turbulent,

* Read at the sixth conference of the Association of Hospital Superintendents of the United States and Canada, at Atlantic City, N. J., September 22, 1904.

the realization that he is near home and may communicate or visit with his friends, has a strongly reassuring effect.

The reasons for the creation of this department were stated to be (1) transient accommodation of insane patients committed to a State institution, and (2) of patients who need observation before the advisability of commitment to a State institution is determined; provision (3) for mild cases of insanity who might recover in a general hospital, (4) for victims of drug addiction; and, as an emergency resort, for (5) rapidly developing and critical cases of delirium, and (6) the sudden and often dangerous forms of mental disorder which occur in the course of general diseases after the shock of surgical operations or anæsthesia.

How well this pavilion has fulfilled the duty outlined above may be seen from the statistical table of the operations of the first two years, terminating February 29, 1904. Three hundred and thirty-one patients were treated, of whom 110 recovered, 96 improved, 88 unimproved, 25 died, and 14 remained under treatment. Twenty-four patients were transferred from other departments of the hospital. A glance at the table shows that all forms of mental disorder have been represented, and that several purely physical diseases have been treated by reason of complicating mental conditions, such, for example, as Bright's disease and puerperal eclampsia.

The plan of the hospital fortunately permitted the addition of a pavilion which could be constructed for its special purpose. Opportunity was given to provide accommodations for restless patients that the disorder might not disturb other wards or even other parts of the same ward. This construction carries with it an important medical principle. It is possible to manage discreetly an excited patient without recourse to stupefying drugs or other methods of repression. Shouting, rattling of furniture, and pounding on the walls or doors are symptoms of active mental disorder, and should be controlled only within certain bounds when endangering the patient himself. By adapting the building to the needs of the patients, isolation and retirement may be secured. It is now possible to close six doors between a noisy patient and the rooms occupied by others. There is little use for interference with the activity of the patient on other ground than his own safety. The motor restlessness characteristic of active mental disturbance may be permitted. This does away with the need of coercive measures, and the therapeutical plan from the mental standpoint may be said to be entirely conciliatory.

Our strong conviction is that disregard of this architectural feature would practically destroy the efficacy of the ward. The necessity of subduing one patient to promote the comfort of his neighbors leads to resistance and resentment on his part and harshness from his caretakers. This is an outrage upon the patient, and a species of malpractice which may easily bring an institution, however meritorious in other respects, into disrepute. The hospital governors further require that no patient shall be treated in this pavilion except by a physician of known and approved training in the specialty of mental diseases.

It is not to be expected that the work of a hospital for the insane can be done in a general hospital. Nor can the work of a general hospital be done in a hospital for the insane. But there are many forms of mental disorder having the character of an acute illness, with disturbance of bodily function, and there are many forms of acute physical disease, with disturbance of mental function, for which the general hospital should provide. Otherwise, it is not a general hospital. The surgeon has every resource for the immediate contingencies of operations, as shock, collapse, hæmorrhage. He is prepared not only to conduct his work in the direct line, but to repair the mischief of possible complications, except one. He has no protection against mental complications. His assistants, physicians, and nurses are without training and his building is without accommodations. These mental manifestations are even more common to medical diseases and require no less the most intelligent treatment.

In conclusion, I wish to state that it is an important moment in hospital history when the Association of Hospital Superintendents takes up this question. It means a great deal to patients suffering from mental disorders, especially in incipient stages, and it means a great deal to the hospital. We hope it may be said, for the credit of all physicians engaged in hospital work, that perfection in resources is not regarded as complete until this phase of acute disease has been met and combated.

ADDENDUM.

Table showing the forms of disease, and the results of treatment from the opening of Pavilion F, Albany Hospital, February 18, 1902, to February 29, 1904:

ABORTIVE TREATMENT OF GONORRHOEA IN MAN. REPORT OF A CASE.*

By GEORGE GROSS, M. D.,
SAN FRANCISCO.

Beginning gonorrhoeal urethritis being for a certain time, a very short time only, however, a purely epithelial process, it is during this initial stadium that the abortive treatment can be resorted to, in order to destroy the gonococci before they have reached the deeper layers of tissues. Highly bactericidal chemical solutions which enable us at the same time through their cauterizing action to effect a superficial but homogeneous destruction of the epithelium over the whole mucous membrane of the anterior canal furnish us the means to that end. Such a chemical agent we possess in the old stand by nitrate of silver, employed, however, in a new way, according to the method applied so successfully by Dr. Engelbreth, of Copenhagen.

Strong solutions of permanganate of potassium used according to the Janet method determine reactions characterized more by effects of irritation than those of cauterization, and produce readily an œdema of the mucosa as well as of the glans and præputium, while nitrate of silver not being an irritating agent, has a purely local ac-

tion. But the old method of using this agent in the abortive treatment of gonorrhœa in man by the hand syringe was defective; indeed, with a urethra of a small capacity, an infection of solutions from one to twelve per cent. as made formerly with a hand syringe, is liable to force the sphincter and cause very serious accidents, even death, while that same injection will be quite insufficient to fill a large sized urethra. Hence Engelbreth concluded that the safest method of employing the nitrate of silver was in the form of a Janet lavage limited to the anterior canal, and the concentration of the nitrate solution must be so much weaker in proportion as its action is intensified by the volume used; indeed, 500 c.c. of a 0.25 to 100 solution employed in lavage are equivalent to a two per cent. solution applied in small quantity. Engelbreth decided on a 1 to 200 solution, of which he uses 500 to 600 c.c. under a pressure of one and one quarter inch at a temperature of 37° C., winding up with an application of three per cent. to the fossa and meatus, and he has recourse to this treatment whenever the infection is fresh, characterized by a purely epithelial irritation, with absence of any inflammation at the meatus, and the first portion of the urine is clear with simple mucous flakes. Consecutively to this application we observe the discharge of a pultaceous mass, which contains the desquamated epithelium and pus cells in suspension amid abundant mucus. Four hours after this first treatment the gonococci have disappeared; he then makes a second lavage with a 1 to 500 nitrate solution in the same manner.

The direct effect of the lavage is a cauterization to a gray white of the mucosa and a sensation of a more or less intense scalding, lasting from one half to one hour, but œdema is absent. The discharge later on becomes a serous fluid, slightly tinged with blood, and within six to eight days the cure is complete. Engelbreth publishes statistics of 26 successful cases on a series of 30. In conformity with the above principles and rules I beg leave to relate the following case:

The patient, an adult 28 years old, had two previous attacks of gonorrhœa; the first about six years before, lasting three months; the second, two years before, lasting one month. For the present attack the patient called just three days after coitus; the meatus at the time presented no signs of inflammation, but the drop of yellowish discharge at the microscopical examination showed the usual characteristic clusters of gonococci, extracellular; this was at 11 a. m. of December 4th.

On this first visit I was making an anterior irrigation with a solution of permanganate 4 grains, to 20 ounces of water, with the addition of 20 c.c. of a one per cent. bichloride solution at 45° C.,

* Read before the California Academy of Medicine, December 27, 1904.

when the patient, enlightened by his previous experience, anxiously inquired whether I could not use a quicker method of cure, as he felt that the disease was only at its start.

Taking into consideration the favorable conditions of the case as well as the good will and determination of the patient to submit to a more severe treatment with the prospect of a speedy cure I proposed at once to employ the Engelbreth method, and four hours later, about 3 p. m., I made the first nitrate of silver lavage with 500 c.c. of a 1 to 200 solution at 37° C., using the first half with a pressure of 75 cm. and the balance with a pressure of 125 cm., without previous cocaineization. The patient bore the treatment bravely without complaining much; the mucous membrane at once took a white grayish appearance, showing a thorough cauterization, and I wound up with an application to the fossa and meatus of a three percent. nitrate solution. Some bleeding occurred for a moment, but all through the ordeal was very well borne; I ordered some triticum repens; the patient from his own accord had already taken some methyloids, and I made an appointment for the second lavage six hours later, i. e., 9 p. m.

At the appointed hour the patient returned and declared that he felt perfectly comfortable, had no frequent desire to urinate; the cotton in the protective hood showed the expected creamy thick discharge, which examined at the microscope showed as we had a right to expect, pus cells in abundance, but gonococci nowhere. The patient urinated freely and without distress. We then made the second formal lavage with a 1 to 500 nitrate solution at 37° C., the first half from 75 cm. pressure, the balance from 125 cm. This application, made also without cocaine, became rather painful towards the end, on account of the manipulation of the meatus with the irrigating cannula or end piece, but the young man got through the ordeal bravely and the sensation of scalding faded away, as after the first séance, within from one half to one hour. This second treatment was made at 9 p. m. The patient slept through the whole night without waking up, and called the following morning at 8.30 before having urinated. We observed a copious creamy discharge; the microscopical examination again showed pus cells in abundance, but no trace of gonococci. The micturition was easy. I stopped all further treatment; simply continued the triticum and measures of cleanliness.

In the afternoon of that second day, the micturition became somewhat painful and little blood was passed with some tenesmus at the end of the function, but there was no frequent desire to urinate; the patient passed at least a pint of urine at the time. The night was as good as the one preceding. The patient urinated about 10 p. m., slept until morning and called again at 8.30 before having urinated. Although we entered only the second day there was hardly any more discharge, but a thin layers of mucus between the lips of the meatus; no trace of gonococci under the microscope. Patient urinated freely, and experienced only a little distress toward the end of the operation, when a few more drops of blood

passed. The night was passed in comfortable sleep as before and the patient called again the following morning at 8.30, with the same cotton over the glans he had gone to bed with. This cotton was almost dry, and the meatus was already reassuming its normal appearance; no trace of gonococci. Micturition easy, hardly any more pain, and the first portion of the urine showed but very little desquamation; the second glass is perfectly clear and only a few drops of blood were passed at the end.

The following day, the fourth day, no trace of secretion, the urine first of all was absolutely clear; the meatus was dry and had reassumed its normal appearance; the urination was absolutely normal and easy, the patient felt as well as ever before, and the case was dismissed cured. It remains cured.

Correspondence.

LETTER FROM PARIS.

The Low Birth Rate.—The Third International Tuberculosis Congress.—A Congress on Quackery.—A Legacy by the Late Professor Tillaux.—Lead Poisoning Among Diamond Cutters.—Adulteration.—Goutre and Cretinism in Khokand.—The Domiciliary Records of Paris.

PARIS, April 20, 1905.

A Parisian physician announces that the low birth rate in France is due to alcoholism. The Parisian atmosphere is too pleasant a one to permit me to be unduly captious, yet I think it well to point out that the statement is not true. The brutal truth is that the low birth rate in France is due: (1) To the use of means to prevent conception; (2) to the destruction and removal of the fetus after conception, either instrumentally or by the use of abortifacients. If these causes are considered, we shall see that all other causes may be neglected. Wages are so low here, and the many little luxuries that habit has made necessities bring the expenses of living to such a point, that children are very unwelcome even in the case of those who are veritably married, married *devant le Maire*. How much more unwelcome must the little visitors be in those *menages* where the only ties are those of convenience? In fact, the proportion of births that are illegitimate is more than eighty per cent. If eighty per cent. of the children who are born are illegitimate, it seems clear that more than that percentage of the children who are not born are illegitimately prevented from coming into the world. If wages were higher and if life were less complex, France would be at least as prolific as other countries, for nowhere are the women healthier and better animals than here in France.

Under the patronage of the President of the French Republic, the Third International Tuberculosis Congress will be held in Paris, at the Grand Palais, from October 2nd to October 7th. A credit of one hundred thousand francs has been voted toward the expenses of the congress by the legislature. It is the aim of the congress to consider every aspect of tuberculosis and to make a pressing appeal to every element of society to aid in its effectual extirpation.

On May the 8th a Congress on Quackery is to meet in Paris under the presidency of Professor Brouardel. The programme includes twenty-five subjects for discussion, among them being illegal practice of medicine by bone setters, sorcerers, and empirics, by quacks, magnetizers, and clairvoyants, by lay people and clerics for charitable purposes, or under pretense of charity, by members of societies for the aid of the sick and wounded, by nurses, male and female, by "maso-therapists," schools of massage, manicurists, pedicurists, herbalists, medical electricians, etc.

Dr. Tillaux, one of the most eminent surgeons of Paris, whose death was recently announced, bequeathed 500,000 francs to a fund for providing old age pensions for workmen. He rendered much valuable service to the poor as chief surgeon of the Charity Hospital, where he was greatly beloved by all the students.

In the process of diamond cutting, the practice at present obtains of embedding the diamond to be cut in a temporary setting of lead. So many cases of lead poisoning have resulted that the Dutch government has offered a prize of 6,000 florins in a competition open to the world, with the view of discovering a new method of diamond cutting which shall do away with the danger of lead poisoning, either by the provision of a new medium for the setting and resetting of diamonds to be cut or by the substitution of a different plan of work. The Minister of the Interior has appointed a committee of experts to consider the answers submitted and to award the prize.

Parisians who suspect adulteration in the food or drink that they buy take it to the municipal laboratory and have it analyzed free of charge. The city undertakes the prosecution, if need be, of the offender, who, if the case is proved, is liable not only to fine and imprisonment, but to the exposure in his shop window of a notice of "conviction of adulteration."

According to M. Guillaume Capus, the population of the town of Khokand, in Turkestan, consists for the most part of sufferers from goitre and cretinism. The traveller entering the town is at once struck by the fact that nearly every person

he meets is the bearer of a more or less voluminous goitre. Khokand is the only place in Turkestan in which such a state of things exists, and there appears to be nothing in the place or its surroundings to account for the prevalence of goitre and cretinism. Its sanitary condition is satisfactory. The town is situated at a height of 1,300 feet, and is abundantly supplied with water from a river which, like the others in the same region, comes from the Alai Mountains. When the Russian troops occupied Khokand, in 1878, the medical officers noted that a tenth of the garrison became affected with goitre after a few months' stay. The tumors yielded to the iodine treatment; nevertheless it was decided to abandon Khokand and to transfer the headquarters to Marghillan.

In the annex of the Hôtel de Ville in Paris there are kept the records of the houses of Paris, and everything that has happened in any house of the city for the past ten years, that can have any bearing upon medicine or sanitation, is immediately available. Dr. Lamoureux is the founder of this department of the city government. At the present moment this bureau contains, for each house of the city, a series of cards giving the plan of the house, the number of occupants, a description of the furnishing, with the wells, ditches, and stables, near it, the number of deaths and their causes, the number of disinfections, with the dates and the reasons therefor, and, if any insanitary pursuits have been followed, the manner in which the prescriptions of the Bureau d'Hygiène have been followed. From 1894 to 1900 there were tabulated 73,000 descriptions of houses, and from 1900 to 1905, 7,000 more. From 1894 to 1905 there were 138,766 deaths from contagious diseases, and 283,157 disinfections for typhoid fever, scarlatina, variola, tuberculosis, diphtheria, etc. The bureau is open to properly authorized medical men for the purposes of science; otherwise its contents are held secret. Such facts as that in one house of this city, with sixty occupants, there have been since the bureau started (11 years ago), sixty-seven deaths, are to be found in abundance and tabulated.

Therapeutical Notes.

Treatment of Varicose Ulcers with Peroxide of Zinc.—Beurmann (*Annales de dermat. et de syph.*, December, 1904; *Treatment*, April, 1905) has employed peroxide of zinc in powder, and as a 20 per cent. ointment. This is applied to the ulcer and covered with sterilized gauze, which is left on for three to six days. In all cases the secondary infection of the ulcers disappeared, and granulations and cicatrization developed quicker than by other methods.

NEW YORK, SATURDAY, MAY 27, 1905

INFLUENZA AND PRECEDING HYSTERIA.

It seems not unreasonable to suppose that the Protean manifestations of influenza are explicable, at least in some instances, as dependent on morbid conditions present before the acute attack. That they may be modified by hysteria is unquestionable. An interesting example of such an influence exerted by hysteria has recently been reported by Dr. P. Menetrier and Dr. Louis Bloch (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, April 20th).

A woman, twenty-two years old, a hospital nurse, was suddenly attacked with influenza, of which disease there were at the time many cases in the hospital. On the afternoon of the fifth day her temperature was 103° F., she lay curled up in bed, at the same time prostrated and agitated, and answered questions in a feeble and jerky voice. There was general lassitude, with muscular pains, and she was suffering greatly with nausea. Her neck was somewhat stiff, and she occasionally ground her teeth. On the following morning, after she had spent a sleepless night, with agitation, mild delirium, and vomiting, her head was thrown back, the neck being so stiff that her body could be lifted like one piece by the head. This rigidity affected the whole trunk, which was in a pronounced state of opisthotonos. The legs and thighs were obstinately flexed, and Kernig's sign was well marked. She was continually sigh-

ing or murmuring unintelligible words. Her face was grinning, her eyeballs and lids were in incessant motion, and every moment her jaws made movements like those of chewing or she ground her teeth. All the time there was extreme headache, so that she could not bear even a moderate light. She complained of rather severe diffuse abdominal pains, but an examination of the abdomen, which was slightly retracted, revealed nothing special. There was general hyperaesthesia, and the reflexes were exaggerated. There was no disturbance of sight or hearing, and the pupillary reactions were normal, though there was slight convergent strabismus at times. The *tache méningitique* was intense and persistent. On the seventh day the temperature had fallen to 99.5°, but there was still extreme agitation, with delirium, and the movements of the limbs were disorderly, though there were no real convulsions.

On the eighth day the picture was changed; excitement had given place to profound depression. The patient lay silent and motionless. There was no longer any rigidity of the arms or trunk, and Kernig's sign and the stiffness of the neck were less pronounced. The legs and thighs were still flexed, however, and the least attempt to straighten them provoked severe pain. The delirium had wholly disappeared, and the patient answered questions, but in a sighing voice and with an almost infantile intonation. There was no longer any vomiting or headache. On the ninth and tenth days the girl's bodily condition was normal except for a little remaining stiffness of the lower limbs, and she was passing urine abundantly. On the other hand, her mental state was quite peculiar, showing the infantilism (*puérilisme mental*) described by Dupré and Camus and by Soullard as encountered in hysteria, "You know, sir," she said to one of the authors, "they promised to give me a little dog, a little black dog"; and the next morning she was found playing with a little toy dog, showing the most childish joy in its possession. This mental state lasted without abatement for two days, and then began to subside slowly. By the eighteenth day the girl was entirely well in both body and mind.

A month later, on inquiring more closely into

her history, the authors learned that her mother was tuberculous at the time, that her father had long been lost to view, and that she was the eldest of six children and had seen all her five brothers and sisters die of tuberculous meningitis at various ages. When she was five years old, she burned one of her knees slightly, and as a consequence had contracture of both lower limbs for six months. At the age of seventeen she apparently had a light malarial attack in Africa, and at eighteen she had a miscarriage, which was followed by pelvic peritonitis. She had been serving as a nurse for three years, and was tall and robust in appearance. There was a bilateral zone of complete anæsthesia at the level of the breasts, and there was a notable curtailment of the visual field. From the psychical point of view, one could elicit in her a sort of childish vanity; she had an immoderate tendency to make a show of herself, and above all she had an insurmountable longing to engage the attention of people. These facts, taken in connection with the old contracture, evidently neuropathic, seemed to the authors to warrant them in looking upon the girl as decidedly hysterical.

Tracing the connection between the patient's previous history and the cerebral turn taken by her acute symptoms, the authors say: "Let us remember that this young woman had been present at the death of five brothers and sisters, all from tuberculous meningitis, and that these deaths, as she herself said, had profoundly impressed her." Furthermore—and this might fittingly be emphasized to those people who think that hospital patients are apt to be ill treated—they say of their omission to resort to lumbar puncture that it would have been very painful to a person affected with this patient's hyperæsthesia, and that, since by reason of her profession she would have divined the object of its performance, it would have accentuated her preconception that she was doomed to die of meningitis.

THE ANTIQUITY OF SYPHILIS IN NORTH AMERICA.

The question of the original habitat of syphilis has been a prolific source of discussion for a long time now, at all events ever since the time of Astruc, and these three theories have been up-

held: 1. That the disease prevailed in both the eastern and the western hemispheres before the time of the discovery of America by Columbus. 2. That it was unknown in Europe until Columbus's men took it back with them. 3. That it originated in the Old World, and was brought to America by those same men. A recent interesting contribution to the study of the subject has been made by Samuel Torrey Orton, B. S., who gives an account of his observations, under the title of *A Study of the Pathological Changes in Some Mound Builders' Bones from the Ohio Valley, with Especial Reference to Syphilis*, in the April number of the *University of Pennsylvania Medical Bulletin*.

The specimens studied by Mr. Orton belong to the Museum of the Ohio State Archæological and Historical Society, in the city of Columbus. They consist of 127 skeletons exhumed at the Baum Village site, situated in the valley of a tributary of the Scioto River. Twenty-one of these skeletons were found to be diseased, and the lesions were judged to be syphilitic. Mr. Orton's judgment on this point is founded on most painstaking diagnostic distinctions. In his thoroughness he even goes so far as to distinguish elaborately between the lesions of syphilis and those of osteitis deformans, a disease which, though rare now, he admits to himself may possibly have been frequent in the days of the Mound Builders.

His material, as he remarks, undoubtedly antedates the voyages of Columbus, and he justifies his diagnosis of syphilis by the following points: So far as long bones were concerned, the changes observed affected chiefly the diaphyses, with a predominance in the bones most exposed to injury, and consisted of large exostoses and osteophytes with concurrent rarefying and condensing osteitis in the same specimens. In sixty per cent. of the syphilitic skeletons the bones affected, in the order of frequency, were the tibia, the ulna, the cranial bones, and the sternum.

While it is not unlikely that some of Columbus's men were syphilitic before they ever laid eyes on America, manifestly we must not assume that they brought the disease to a continent on which it was before unknown. On the other hand, it is by no means improbable that, as Mr.

Orton suggests, those men found here a "strain" of syphilis so potent that, when they took the infection back to Europe with them, it gave rise to that virulence of the Neapolitan outbreak on which so much stress has been laid as showing the American origin of the disease.

THE NAVAL MEDICAL SERVICE.

The difficulty experienced for a number of years in inducing properly qualified young medical men to enter the medical corps of the navy has doubtless been materially reduced of late, and probably it will be wholly overcome before long. If there still remains something of the haughtiness with which for a considerable period the medical officer was looked upon by the line officer, it must speedily disappear, for it has no substantial basis. When it vanishes for good and all, the medical man's career in the navy will be as satisfactory as that of the man who is wedded to deeds of arms. Moreover, it is an error to suppose that a physician who is devoted to his profession is doomed to stagnation if he enters the navy. In the first place, there is the opportunity of taking the excellent course of advanced study pursued in the Naval Medical School, the advantages of which are very lucidly set forth by Dr. James Nevins Hyde in the May number of the *Journal of the Association of Military Surgeons of the United States*. The course, as Dr. Hyde points out, is such as to improve the young medical officer's physical condition as well as to enhance his professional acquirements.

Then there is the satisfaction of belonging to a corps that has such an honorable history, a sketch of some of the salient points of which is given in Dr. Hyde's article. From John Paul Jones's surgeon on the *Ranger*, Dr. Ezra Green, down to the assistant surgeon of the present day, the successor of the old time "surgeon's mate," the achievements of our naval medical officers have been such as to stimulate emulation in those who may hereafter join the corps. It is not in time of war only that the naval medical officer has a rich field for the application of his attainments. Hygiene, preventive medicine, and especially the study of tropical medicine, almost a novelty to us Americans, will amply employ his

abilities and gratify his taste for investigation. A more useful career than that of the naval surgeon could hardly be imagined.

THE LOCAL DRY HOT AIR APPLICATION IN GENERAL PRACTICE.

One of the most useful of that group of remedial measures which have become so prominent during the past seven or eight years, the so called physiological therapeutic agents, is dry hot air. It is also one that, in spite of the many articles that have been written regarding it, is still unappreciated so far as many of its most helpful curative and palliative properties are concerned. So far as the average general practitioner is concerned, the general, or body, dry hot air application may be at once eliminated from this discussion; the necessary equipmental accessories in the way of rooms, skilled attendants, bathing and lounging facilities, etc., are so elaborate as to render unreasonable an expectation that he should have them at his personal command. The local application, however, is sufficiently simple, as regards both the apparatus and the technique involved, to bring it within the reach of any general practitioner, and the therapeutical results attainable with it are satisfactory.

A prime requisite, as regards construction of the local apparatus intended for use by the general practitioner, is that it be easily transportable from place to place; hence lightness, compactness, and simplicity are valuable attributes. These machines are furnished complete, with flexible attachments for directing the heat upon the various regions of the body, by the manufacturer; also attachments specially adapted for the use of gasoline, gas, alcohol, or electricity as the source of heat. Gasoline and gas are most generally used, and both are practically efficient when the conditions, as regards volume of supply available, etc., are adequate. If one is never going to apply this agent outside of his own specially equipped operating room, gas will, under ordinary conditions, be the most satisfactory of any, but the general practitioner will frequently need to apply it at his patient's bedside in a house wherein gas is not available in sufficient quantity or under sufficient pressure to give the required degree of heat. For

these reasons gasoline constitutes the agent *par excellence* for the general practitioner to employ as a source of heat, and if a proper degree of care is brought to bear upon its manipulation, explosions or other accidents contingent upon the nature of the fluid need never occur.

Among the more important conditions commonly encountered in general practice in the treatment of which local applications of dry hot air render valuable service are sprains, acute articular rheumatism, various forms of early septic infection, and pneumonia.

Sprains.—The local dry hot air treatment, administered at 350° F., will completely relieve the pain accompanying a sprain in half an hour; if the pain is not so relieved it is very safe to conclude that a fracture is present. If the injured joint is placed under treatment by this agent within five or six hours after the accident, complete recovery will have supervened within forty-eight hours in the vast majority of cases. The employment of dry hot air at any stage of the trouble may be relied upon to shorten the period of convalescence at least fifty per cent.

Acute Articular Rheumatism.—By this term is meant true rheumatic fever, not the various inflammatory, degenerative, and irritative processes affecting bone, nerve, and muscle structures which are so often miscalled by this term. The results of its use in this condition may be briefly summarized as follows: 1. Immediate relief of pain, which relief may be rendered continuous by repeating the treatment as often as the pain manifests a tendency to return. 2. A marked shortening of the duration of the attack, which usually lasts from five to ten days only when dry hot air and salicylic acid are employed in combination. 3. Diminished probability of cardiac involvement, because of the rapid control obtained over the pathological conditions, whereby the time during which the infection is apt to involve other structures is shortened.

Local Septic Infection.—In the majority of instances met with in general practice the infection takes place in the distal portion of some one of the extremities. If the case is got under treatment with dry hot air before the process has involved that portion of the limb immediately contiguous

to the trunk, the pathological phenomena will usually be abruptly arrested and the inauguration of convalescence will coincide with the first treatment. If glands or other tissues have not been "poisoned" beyond the possibility of redemption, they will be regenerated and the ominous picture will fade uneventfully away; if the destructive influence has gone far enough to render suppuration inevitable, however, the latter process will be hastened and at the same time sharply localized about the focus of disintegration, when a stroke of the knife will end the condition most satisfactorily.

Pneumonia.—In the rapidly fatal cases characterized by profound, general, systemic toxæmia the local dry hot air application is of little use, but no measure is more conducive to the comfort of the patient or more helpful in obtaining a favorable termination in this disease as it is ordinarily encountered. The pleuritic pain, together with that proportion of the respiratory acceleration and nervous irritation dependent thereupon, can be relieved in a few minutes, and the pleurisy itself with the resultant cough will have disappeared in a few hours. How much this means in many cases can readily be appreciated. The most striking effect of local dry hot air applications in this disease, however, is observed in connection with the phenomenon of consolidation. A treatment every ten or twelve hours will remove the physical signs of consolidation in from two to five days; the danger of heart failure from massive exudate, but not from toxæmia, of course, is thus practically done away with. The patient usually begins to improve immediately after the first application, and although the course of the disease is not shortened, the severity of the symptoms is greatly lessened.

Many other pathological conditions in which local dry hot air treatment is valuable might be cited, but the foregoing are sufficient to indicate its helpfulness in general practice. The physiological action of the measure, from which may be deduced its clinical applicability, may be summarized as follows: 1. Immediate relief of circulatory stasis. 2. Greatly increased blood supply to the part treated. 3. Marked acceleration of the nutritive processes of the

part treated, due to reflex stimulation of the trophic nerve supply. 4. An increase in the temperature of the part treated, whereby the chemical reactions constituting local metabolism are markedly facilitated. It is probably through intensification of local physiological resistance, brought about by these four effects, that the inhibitive influence upon the development of pathogenic microorganisms that may be present in the part is secured. 5. The withdrawal of a large amount of fluid from the part treated by reason of the profuse perspiration induced, which carries out with it a certain proportion of toxins that may be in process of elaboration.

In addition to the ascertained physiological effects, the clinical experience thus far recorded, both in this country and abroad, demonstrates that the efficiently administered local dry hot air application is a therapeutical element of marked value, that it accomplishes some results that cannot be accomplished by any other measure, and produces some effects in a better and more efficient manner than other measures, wherefore it merits extended study and a prominent place in the modern management of disease.

CLARENCE EDWARD SKINNER.

POSTGRADUATES.

Dr. Ely Van de Warker, in his article in this issue of the *Journal* on The Surgical Paradox, recommends that students of postgraduate institutions be compelled to pass special State board examinations before being loosed on the community as specially qualified surgeons and gynecologists. The suggestion is an excellent one, but the examination should be of a practical nature, as a written test which, as we have frequently pointed out, it requires only a good memory to sustain triumphantly, would not safeguard the public in the slightest degree.

THE LUNCH COUNTER TOWEL.

There can be little doubt that the towel sometimes observed hanging from a lunch counter is among the more mischievous of the avoidable means of conveying contagion. Fortunately it is not so common as it was a few years ago, but it ought not to be tolerated at all. In the best establishments an individual napkin is furnished even with a glass of beer, and by insisting on it the public can obtain its provision everywhere.

News Items.

Society Meetings for the Coming Week:

TUESDAY, May 30th.—Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private).

WEDNESDAY, May 31st.—Auburn, N. Y., City Medical Association; Berkshire, Mass., District Medical Society (Pittsfield).

THURSDAY, June 1st.—New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, June 2nd.—Clinical Society of the New York Post-graduate Medical School and Hospital; Manhattan Clinical Society; Baltimore Clinical Society.

SATURDAY, June 3rd.—Manhattan Medical and Surgical Society, New York (private); Miller's River, Mass., Medical Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending May 20, 1905:

	May 20.		May 13.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	760	10	742	14
Diphtheria and croup	345	36	312	36
Scarlet fever	201	13	235	13
Smallpox	1	1	6	1
Chickenpox	152		129	
Tuberculosis	410	155	474	195
Typhoid fever	23	9	37	3
Cerebrospinal meningitis	99	72	136	88
	2,000	296	2,071	350

Personal.—Dr. Jacob Sobel has been appointed adjunct pædiatrist to the Sydenham Hospital.

The New York Eye and Ear Infirmary.—Consulting physicians have recently been appointed as follows: Dr. Walter B. James, Dr. George T. Elliott, and Dr. Walter Lester Carr.

Memorial Hospital Training School for Nurses.—This Brooklyn institution graduated the following nurses on May 24th: Bertina S. Scott, N. Elleda Pollock, Rita Louise Pearwin, Elizabeth Scott, Ethel Mitchell Scott, Bessie Louise Ramsay, and Milly Larson.

St. Vincent's Hospital has graduated the following young women as nurses: Lillian A. O'Farrell, Mary A. Gillis, Isabel O'Donovan Rossa. Susie A. Lant, Anna R. McPartland, Margaret M. McNichol, Lucy B. Lee, Josephine M. Lindsay, Alice M. Kelly, Matilda M. Burke, Grace E. Leonard, Adelaide F. Sullivan, Katherine E. Shea, Mary A. Shannon, Katherine C. Sullivan, Josephine A. Allison, Bridget T. McKeon, Julia A. Sheehan, and Katherine M. Kentler.

St. Mary's Hospital, Brooklyn, Training School has granted diplomas to the following trained nurses: Gertrude Dilger, Mary Elizabeth MacCurry, Mary Alice Burke, Margaret Cummings, Mary Ethel Daly, Emily Fajans, Katherine Daffin, Mary Manning, Sara Clendinning, Margaret Kastania, Mary Walsh, Jeannette Hargan, Arra Thurtell, Mary Carlin, Helen Warburton, and Gertrude Curley.

Kingston Avenue Hospital, Brooklyn.—Health Commissioner Darlington opened on May 14th

the new wing at the Kingston Avenue Hospital, Brooklyn, which will be used exclusively for the treatment of scarlet fever cases. The new structure is one of the best equipped buildings of its kind in the country. "In spite of my issuing more than 2,000 invitations," said Dr. Darlington, "less than fifty persons were present. I suppose the good people of Brooklyn and Manhattan were afraid of the smallpox scare, but ample precaution was taken to make their presence perfectly safe. I consider this new department to be the finest connected with any contagious hospital in the world and its equipments are as near perfect as it is possible to procure. More than eighty patients can be housed without overcrowding."

The Postgraduate School and Hospital.—At the annual meeting of the faculty of the Postgraduate Medical School and Hospital, held on May 10th, the announcement was made that its members had pledged themselves to raise \$40,000 for the institution before next Thanksgiving. This \$40,000 will go toward making up the \$100,000 which must be raised by popular subscription before an anonymous gift of \$100,000 recently made to the institution, and already announced, will become available. At the meeting Dr. D. G. St. John Roosa was reelected president, and Professor James N. West was elected secretary, to succeed Dr. Forbes Hawkes, resigned. Eight instructors were appointed. Announcement was made that the new obstetrical department of ten beds would be established, and the former announcement of the establishment of a new school of anatomy was confirmed. The board of directors held a meeting and ratified the faculty election.

Twenty Thousand Dollars for Mount Sinai Nurses.—With the object of offering an inducement to the pupils of the Mount Sinai Training School for Nurses to obtain the highest possible proficiency, Mr. Murry Guggenheim has established a fund of \$20,000, the income from which shall be applied to create twelve scholarships of one hundred dollars each annually, subject to the following regulations and conditions: First, six of these scholarships to be assigned to junior pupils, three to senior pupils and three to members of the graduating class. By the attainment of suitable proficiency any nurse can secure all three scholarships during the term of her tuition. Second, the scholarships to be awarded at the annual graduation exercises, taking place in May of each year, together with a pin for each graduating nurse securing one or more scholarships, engraved Murry Guggenheim Scholarship, together with the numerals indicating the year or years in which the scholarship was secured. Third, scholarships to be awarded to those nurses in each class who shall have displayed the highest degree of proficiency in accordance with the existing method of rating. Fourth, the fund to be known as the Murry Guggenheim Scholarship Fund.

PHILADELPHIA.

Scientific Society Meetings for the Week Ending June 3, 1905.—Thursday, June 1st, Obstet-

rical Society. Friday, June 2nd, American Philosophical Society.

Marriage.—Dr. T. K. Means, of Geneva, N. Y., and Miss Anna Marie Wolfe were married on May 16th.

The Philadelphia College of Pharmacy held its commencement exercises on May 14th, 15th, and 16th. On the 14th Dr. David M. Steele delivered the baccalaureate sermon and on the 15th the alumni association gave a reception to the graduating class, at which Dr. Henry Beates, Jr., delivered an address, and the alumni prizes were awarded. The class numbered 127.

Entertainments in Aid of Charities.—A public tea and reception were given on the grounds of the Jewish Hospital on May 17th for the purpose of allowing inspection of the grounds and buildings.

The Enterprise Dramatic Club gave an amateur theatrical entertainment on May 16th for the benefit of St. Agnes's Hospital.

Charitable Bequests.—By the will of Joseph Louchheim, probated May 16th, the Jewish Maternity Home receives \$1,000; the Jewish Hospital, \$1,000; the United Hebrew Charities, \$500; the Jewish Foster Home, \$500. These bequests are made on consideration of the foundation of a free bed, memorial, or other remembrance of the testator.

Jewish Maternity Hospital Nurses Graduate.—On May 17th Miss Monterey Elizabeth McIntosh, of Wilmington, N. C.; Miss Catherine Burns, Miss Henrietta Mumford MacClellan, and Miss Daisy Margaret Burke, of Philadelphia; and Miss Lillie Margaret Clover, of Paterson, N. J., graduated from the training school of the Jewish Maternity Hospital. Dr. David Riesman delivered the address.

The Health of the City.—During the week ending May 13, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	155	23
Scarlet fever.....	31	0
Chickenpox.....	67	0
Diphtheria.....	54	11
Cerebrospinal meningitis.....	5	2
Measles.....	73	0
Whooping cough.....	1	0
Tuberculosis of the lungs.....	37	61
Traumatism.....	26	28
Erysipelas.....	7	1
Tetanus.....	2	0

The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 9; diarrhoea and enteritis, under two years, 14. The total deaths were 455, in an estimated population of 1,438,318; corresponding to an annual death rate of 16.45 per 1,000 population. The total infant mortality was 82; 71 under one year, and 11 between one and two years. There were 32 still births, 14 males and 18 females. No unusual meteorological phenomena were reported by the weather bureau.

Woman's Medical College.—The fifty-third annual commencement of the Woman's Medical College of Pennsylvania was held on May 17th. Fifty-two women from all parts of the world, in-

cluding Armenia and China, received diplomas. Miss Li Bi Cu, of Huighua, China, received high honors. On the 16th the graduating class gave a dinner in the gymnasium of the college. The following is the list of graduates:

Edith V. Beall, Matta L. Berry, Agnes M. Carothers, Margaret S. Crockett, Mary E. Conser, Li Bi Cu, Eveleen A. Doudredou, Mary R. Findlater, C. B. H. Gilmore, Agavine Glibakian, Elsie Graf, Lucinda B. Hatch, Blanca H. Hillman, Millicent B. Hopkins, Alice E. Johnson, Mary E. Jones, Edith C. Kline, Florence E. Kraker, Marie G. Langdon, Elizabeth F. Lewis, S. M. Lichtenwalner, Ethel M. Lyon, Margaret Mace, Myrtelee M. Moore, Winnie K. Mount, Genevieve A. Neil, Abbie M. O'Keefe, Mathilda Osborne, Helen P. Proctor, Jacobina S. Reddie, Annie M. Robinson, Maude W. Sathell, Marcella L. Schweitzer, Katharine B. Scott, Mary F. Shedwick, Rose B. Sheridan, Alice W. Smith, Florence I. Staunton, Alice A. Steffian, Annie H. Thomas, Edith T. Waldie, Lucy M. Warner.

Appropriations for Charitable Purposes Approved by Governor Pennypacker.—The practice of appropriating public money for the support of private charities in Pennsylvania has grown until it is now considered a part of the duty of each legislature to pass bills aggregating many millions of dollars for the partial support of hospitals, etc. The legislature received a report from the State Board of Charities early in the year, in which appropriations were recommended for various institutions of the kind mentioned. The list of Philadelphia hospitals and homes with the recommended appropriation for each will be found on page 241 of our issue of February 4th. The legislature frequently appropriates more money to some institutions than the State Board of Charities recommends and the Governor has to reduce the appropriation made to correspond with the income of the Commonwealth. As the *Public Ledger* said editorially, in its issue of May 14th:

"... The Governor has done his 'scaling down,' according to his best judgment . . . , but such an exercise of judgment ought not to be required of any one man." We give a list of Philadelphia medical charities and the amount of public money each will receive after the cut made by the Governor has been deducted from the legislative appropriation:

University of Pennsylvania and Hospital, \$350,000; Jefferson Medical College Hospital, \$260,000; Medico-Chirurgical College Hospital, \$225,000; Philadelphia Polyclinic Hospital, \$65,000; Woman's Medical College Hospital, \$25,000; St. Timothy's Hospital, \$24,500; Kensington Hospital for Women, \$5,000; Rush Hospital for Consumptives, \$50,000; St. Mary's Hospital, \$15,000; St. Joseph's Hospital, \$22,000; St. Agnes's Hospital, \$40,000; St. Christopher's Hospital, \$15,000; Philadelphia Lying-in Charity, \$12,500; Orthopaedic Hospital, \$27,000; Maternity Hospital, \$5,000; Gynæcean Hospital, \$25,000; Samaritan Hospital, \$80,000; German Hospital, \$50,000; Howard Hospital, \$7,000; West Philadelphia Hospital for Women, \$7,500; Wills's Eye Hospital, \$40,000; Frankford Hospital, \$50,000; Jewish Hospital, \$15,000; Frederick Douglass Hospital (for colored patients), \$12,000; Woman's Hospital, \$35,000; Northern Home for the Friendless, \$11,500; Nazarene Home, \$7,500; Rosine Home, \$4,000; Friends' Home for Children, \$4,000; Philadelphia Working Home for Blind Men, \$35,000; Home for Aged Veterans, \$7,500; Home for the Aged, \$4,000; Old Ladies' Home, \$7,000; Hayes Mechanics' Home, \$4,000; Evangelical Home, \$2,000; Philadelphia Protectory, \$50,000; Home for Incurables, \$10,000; House of the Good Shepherd, \$13,000; St. Vincent's Home, \$2,500; Pennsylvania Anti-Cruelty Society, \$5,000.

It has been said that Governor Pennypacker has made his cuts without apparent reason, ex-

cept for his personal interests in the objects for which money was appropriated; but a comparison of this list with the list published in February will show that the moneys to be received by the various institutions corresponds fairly well with the amounts recommended by the State Board of Charities. Hospitals throughout the State appear to have done quite as well in the matter of liberal appropriations as the Philadelphia institutions.

GENERAL.

The Steuben County, N. Y., Medical Society has elected the following officers: President, Dr. F. H. Starr, of Corning; vice-president, Dr. Herbert B. Smith, of Corning; secretary and treasurer, Dr. W. W. Smith, of Avoca.

The Greene County, N. Y., Medical Society elected the following officers at their meeting in Cairo on May 9th: President, Dr. Percy G. Waller, of New Baltimore; vice-president, Dr. L. B. Honeyford, of Cairo; secretary, Dr. Robert Selden, of Catskill; treasurer, Dr. C. E. Willard, of Catskill.

The Association of American Physicians elected the following officers at Washington on May 17th: President, Dr. Frank Billings, of Chicago; vice-president, Dr. F. Kennicutt, of New York; secretary, Dr. Henry Hun, of Albany; recorder, Dr. Solomon Solis-Cohen; treasurer, Dr. J. P. Crozer Griffith, of Philadelphia; and councilor, Dr. T. Mitchell Prudden, of New York.

The Cleveland College of Physicians and Surgeons graduated the following on May 3rd:

Samuel Sargis Badal, B. S.; Charles Calderine Crawford, Ph. G.; Albert Mealy Dunlap, James Gordon Grimm, Philip Abraham Jacobs, Albert H. Lanzer, Charles Henry McFarland, Jr., Charles H. Merrill, Herbert Leslie Plannette, Armand John Prudhomme, Milo Pember Rindge, Arthur Pflieger Schulze, Eugene Ariel Spenzer, Ph. G.; William Colegrove Tuckerman, A. B.; Harry Holliday Ward, Ph. C., and Franklin Reuben Walters.

Chicago Neurological Society.—A meeting of this society was held at the Sherman House, Thursday, May 25th, at 6.30 p. m. Dr. Hugh T. Patrick presented a case of ataxic paraplegia; Dr. Julius Grinker, a case of traumatic dementia, a case of syphilis of the peripheral nervous system, and a brain from a case of syphilitic hemiplegia; Dr. D'Orsay Hecht read *A Study in Dementia Præcox*. L. Harrison Mettler, M. D., secretary and treasurer.

The Louisiana State Medical Society, at its meeting in New Orleans on May 11th, elected officers for the ensuing year as follows: President, Dr. C. J. Ducote, of Avoyelles; first vice-president, Dr. J. F. Oechsner, of Orleans; second vice-president, Dr. J. J. Ayo, of Lafourche; third vice-president, Dr. D. R. Sartor, of Richland; councillors: Second congressional district, Dr. E. S. Graner, of Orleans; third congressional district, Dr. H. L. Ducrocq, of Lafourche; fourth congressional district, Dr. N. K. Vance, of Caddo; fifth congressional district, Dr. R. F. Harrell, of Lincoln; sixth congressional district, Dr. C. M. Sitman, of St. Helena; seventh congressional district, Dr. C. A. Gardiner, of St. Landry.

State Board of Medical Examiners of New Jersey.—The regular examination for the State medical license of New Jersey will be held at Trenton, June 20th to 21st. Applications for the examination must be filed with the secretary prior to June 10th. Applicants who cannot present a high school diploma, or its equivalent, may take a county examination for teachers on the first Friday and Saturday in May, or the State examination for teachers on the second Thursday, Friday, and Saturday in June.

National Fraternal Sanitarium for Consumptives.—Fraternal City, New Mexico, the location of the National Fraternal Sanitarium for Consumptives, the largest hospital for the treatment of tuberculosis, was founded on May 10th in St. Louis by the officers of the fraternal organizations that have undertaken the work. The formal announcement of the new city, which will be located six miles west of Las Vegas, was made at a banquet at the Planters Hotel. A gift of \$1,000,000 in property, including the Montezuma Hotel, a smaller hotel and a dairy farm, a hospital and 1,000 acres of land was presented to the sanitarium by the Atchison, Topeka, and Santa Fé Railroad. The city of Las Vegas gave 10,000 acres of the most fertile land in New Mexico and by next fall, when Fraternal City will be dedicated, accommodations will be ready for 5,000 sufferers, be they rich or poor, regardless of creed. Patients will be supported without thought of commercialism by per capita contributions made by the great fraternal and religious orders of the country which have brought the sanitarium to its present status after three years of incessant effort. The formal papers, insuring the gift of the Santa Fé, were signed on May 15th in the office of the sanitarium in the Chemical Building. President William R. Eidson, of the Associated Fraternities, and Secretary Charles F. Hatfield represented the sanitarium; W. B. Janson, assistant to the president of the railroad, represented the Santa Fé, and F. H. Pierce the city of Las Vegas. The sanitarium now includes fifteen square miles of cultivated land at an average elevation of 6,000 feet. In the centre of the tract is the Montezuma Hotel, erected by the Santa Fé at a cost of \$500,000. It is built of brick and stone, four stories high, with 350 rooms and 750 feet of veranda.

Conference of Health Officials in Michigan.—The eighth general conference of these officials will be held under the auspices of the Michigan State Board of Health, in Ann Arbor, June 1st and 2nd, with the following programme of papers:

A Statement of the Objects of the Conference, by Dr. Victor C. Vaughan; Municipal Water Supplies, by Mr. Gardner S. Williams; The Status of Typhoid Fever at Escanaba, by Dr. Oscar C. Breitenbach; Report on the Sanitary Analyses of Drinking Water Made in the Hygienic Laboratory of the University of Michigan from January 1, 1904, to June 1, 1905, by Professor John F. Eastwood; Report on the Year's Work in the Pasteur Institute, University of Michigan, by Dr. Thomas B. Cooley; Disinfection with Formaldehyde Saturated with Potassium Permanganate, by Dr. James G. Cummings; Modern Sanitation, by Dr. Malcolm C. Sinclair; The Benefits of a State Sanatorium for Tuberculosis, by Dr. Angus McLean; Organized Effort in Restricting Tuberculosis, by Dr. Thomas M. Koon; General

Discussion on Tuberculosis, opened by Dr. Frank W. Shumway; The Heating and Ventilation of Residences, by Mr. John R. Allen; Restriction of Smallpox, by Dr. Thomas B. Cooley; The Milk Problem, by Dr. Guy L. Kiefer; Discussion of the Milk Problem, by Professor Charles E. Marshall; Street Flushing the Most Rational Means of Abating the Dust Nuisance, by Dr. A. H. Côté; The Malarial Parasites of Birds, by Dr. F. G. Novy; General Discussion on the Powers and Duties of Health Officers.

The objects of the conference are: The presentation of facts and the general comparison of views by the health officers and other delegates of local boards of health, among themselves, with the members of the State Board of Health and with those in charge of the State Laboratory of Hygiene, and especially with reference to the duties of supervisors and other presidents of local boards of health, health officers, and other officials, relative to the restriction of the dangerous communicable diseases and relative to other subjects bearing upon the public health service of the State.

This will not be a medical conference; it is for all health officers and delegates, professional and non-professional. It is expected to have the most advanced scientific presentation of facts in important branches of sanitary science; and it is hoped that public health administration will be dealt with by health officers and others who have had experience, or have given those subjects much thought. Such discussions are not restricted except by the shortness of time at the disposal of the conference. A programme will be issued later. Frank W. Shumway, M. D., secretary, Michigan State Board of Health.

American Laryngological, Rhinological, and Otological Society.—The eleventh annual meeting of this society will be held in Boston, June 5th, 6th, 7th, and 8th, when it is expected that the following papers will be presented:

Killian's Inspection of the Trachea and Esophagus, by Dr. H. P. Mosher, of Boston; The Otoprojectoscope: Demonstration of a New Apparatus and Its Application, by Dr. Max A. Goldstein, of St. Louis; Presentation of Instrument, by Dr. Walter A. Wells, of Washington; Stenosis of the Eustachian Tube a Factor in Postoperative Mastoid Fistula and in Chronic Suppuration of the Middle Ear, by Dr. Thomas Hubbard, of Toledo; Report of a Case of Carcinoma of the Larynx, by Dr. S. E. Solly, of Colorado Springs; An Unusual Case of Laryngeal Syphilis Requiring Tracheotomy, by Dr. Clement F. Theisen, of Albany; "Symposium"—Intracranial Complications of Middle Ear Suppuration: Symptomatology Diagnosis and Treatment of Meningitis, by Dr. S. MacCuen Smith, of Philadelphia; Symptomatology, Diagnosis, and Treatment of Encephalitis and Brain Abscess, by Dr. F. L. Jack, of Boston; Symptomatology, Diagnosis, and Treatment of Sinus Thrombosis, by Dr. James F. McKernon, of New York; Pathological Findings, by Dr. Thomas J. Harris, of New York; Tinnitus Aurium and Hallucinations of Hearing, by Dr. William S. Bryant, of New York; "Symposium"—Diseases of the Accessory Sinuses: Frontal Sinusitis, Diagnosis, Treatment, and Results, by Dr. C. G. Coakley, of New York; Ethmoid, Maxillary Antrum, and Sphenoidal Sinus Operations and Results, by the Nasal Route, by Dr. Walter A. Wells, of Washington; By the Maxillary Route, by Dr. T. P. Berens, of New York; By the External Method, by Dr. Lewis A. Coffin, of New York; Two Cases of Successful Obliteration of the Frontal Sinus After Repeated Operations, by Dr. H. Holbrook Curtis, of New York; Further Experience with Radical Operations for Empyema of the Frontal Sinus, by Dr. W. Freudenenthal, of New York; Report of a Case Simulating Abscess of the Antrum of Highmore, Caused by an Odontome, by Dr. William H. Haskin, of New York; The Significance of Oedema, by Dr. J. E. Schadle, of St. Paul, Minn.; Nose, Throat, and Ear Complications of the Exanthemata, by Dr. John H. McCollom, of Boston (by invitation); Prize Essay. The H. Holbrook Curtis Prize of \$100. Topic: The Etiology and Treatment of Mycosis Occurring in the Upper Respiratory Tract, by Dr. John Sendziak, of Warsaw, Russia; The Indications for Operating in Acute Mastoiditis, by Dr. Philip D. Kerrison, of New York; The Larynx in Typhoid Fever, by Dr. Chevalier Jackson, of Pittsburgh; Acute Suppurative Otitis Media in Typhoid Fever. Report of a Case with Autopsy, by Dr. Ewing W. Day, of Pittsburgh; The Serum Treatment of Hay Fever, by Dr. H. W. Loeb, of St. Louis; Report of Seven Cases

of Intracranial Operations During 1904, by Dr. George F. Cott, of Buffalo; "Symposium"—Syphilitic Manifestations in the Upper Air Passages: Nose and Accessory Sinuses, by Dr. James E. Logan, of Kansas City, Mo.; Nasopharynx, Ear, and Buccal Cavity, by Dr. J. A. Stucky, of Lexington, Ky.; Larynx and Trachea, by Dr. Francis R. Packard, of Philadelphia; Scarletinal Otitis, by Dr. F. B. Sprague, of Providence, R. I.; Report of a Case of Brain Abscess, following Acute Otitis Media. Operation—Recovery, by Dr. T. H. Halsted, of Syracuse; Orbital and Meningeal Infection from the Ethmoid Cells. Death. Report of a Case, by Dr. James F. McCaw, of Watertown, N. Y.; Report of a Case of Suppurative Infection of the Maxillary Sinus, by Dr. Irving E. Kimball.

Statement of Mortality in Chicago for the Week Ending May 13, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	May 13, 1905.	May 6, 1905.	May 14, 1904.
Total deaths, all causes.....	450	530	531
Death rate per annum per 1,000.....	11.79	13.88	14.35
By sexes—			
Males.....	254	311	310
Females.....	196	219	221
By ages—			
Under 1 year.....	70	93	73
Between 1 and 5 years.....	35	68	33
Over 60 years.....	103	88	118
Principal causes of death—			
Acute intestinal diseases.....	14	22	25
Apoplexy.....	13	12	21
Bright's disease.....	42	38	40
Bronchitis.....	14	14	10
Consumption.....	62	74	60
Cancer.....	17	15	20

Suicide.....	10	11	9
Violence (other than suicide).....	26	40	31
Whooping cough.....	14	13	0
All other causes.....	82	94	108

For the first time this year the mortality among children under five years of age has been lower than the average of the season. The ten year May average of this age group has been 27.9 per cent. of the total mortality. For the week of May 13th it was 23.3 per cent. of the total, or more than 16 per cent. less than the average. Of the eighty fewer deaths than reported during the previous week from all causes and at all ages fifty-six were of those under five years of age, and the unusual mortality among infants and young children that has obtained since the first of the year seems to be abating. Pneumonia and consumption are again tied—sixty-two deaths each—as leaders of important causes of death, and show reductions from the previous week of twelve and twenty-three, respectively. The seventh death from cerebrospinal fever since the first of the year occurred in the County Hospital on the 9th inst. The victim was another Italian immigrant, 20 years old; ill on arrival, May 7th, removed from train to hospital same day and died forty-eight hours later. Chief Medical Inspector Spalding reports thirty-three cases of smallpox removed to the Isolation Hospital during the week. Not one of these had ever been revaccinated and twenty had never been vaccinated at all. Three were school children in attendance on false certificates of vaccination and five were children under the school age—the victims of parental criminal neglect.

St. Louis University.—The following graduated from the medical department of this university on May 8th:

William Arthur Atkins, of Mentor, Mo.; Shelby Atkinson, of Ruston, La.; Philip Morris Baker, of Memphis, Mo.; Clarence Melvin Barr, of Beason, Ill.; Floyd William Bennett, of Elwood, Mo.; John Dalus Boggs, of Fairfield, Ill.; Jack Winton Brown, of La Junta, Colo.; Orville Harry Brown, of Sabetha, Kas.; William Jonathan Browning, of Ogden, Utah; Henry Fred Busse, of Red Bud, Ill.; Charles Eugene Caffee, of Verona, Miss.; Charles Burr Caldwell, of Monticello, Ill.; Samuel Kelly Campbell, of Warrensburg, Mo.; Henry Oliver Carlton, of Macedonia, Ill.; George Alfred Carreras, of St. Louis, Mo.; Samuel Davidson Carrigan, of Odin, Ill.; William Joseph Carter, of Gays, Ill.; Joseph Quintin Cooper, of Columbia, Mo.; Elmer Eaton Curtis, of Beloit, Kas.; Edgar Frank DeVilbiss, of Spring Garden, Mo.; Eugene George Dinges, of Red Bud, Ill.; Thomas David Doan, of Hopeadel, Ill.; Theodore Jordan Drisdell, of Everton, Mo.; William Albion Dulaney, of Marlow, Ill.; Oscar Allen Duncan, of Conway Springs, Kas.; John William Dunn, of Dietrich, Ill.; August Dutzi, of St. Louis, Mo.; Joseph John Ehresmann, of New Munich, Minn.; John Wesley Ellis, of Lampasas, Tex.; Frank Bertie Farrington, of Clarksburg, Mo.; Charles Hamilton Farthing, of Odin, Ill.; Ulysses Charles Fattebert, of San Luis Potosi, Mexico; Joseph Allan Fisher, of Ganntown, Ill.; Caspar Hartman Foote, of St. Elmo, Ill.; Hannibal Claude Fortune, of Pleasant Hill, Ill.; William Henry Foster, of Mount Auburn, Ill.; Joseph Henry Gann, of Ganntown, Ill.; Oliver Crockett Gebhart, of St. Joseph, Mo.; Charles Oscar Giese, of Mount Pleasant, Ia.; Elmer Newton Glascock, of Raleigh, Ill.; George Butler Godfrey, of Pomona, Tenn.; Henry Philip Graul, of St. Louis, Mo.; William Fred Henry Grote, of St. Louis, Mo.; Mayfield Delmar Hamm, of Sweet Springs, Mo.; Charles Foster Henderson, of Paris, Mo.; William Terry Henderson, of Ruston, La.; Charles Fred Henke, of St. Louis, Mo.; Elmer Eugene Hinckley, of Fillmore City, Utah; Walter A. Hodges, of Hillsboro, Ill.; Walter Louveria Hougland, of Mattoon, Ill.; Harry Samuel Hughes, of Hillsboro, Ill.; Leo Francis Hummer, of Iowa City, Ia.; George Alexander Johnson, of Bethwell, Ontario; Charles Roy Johnstone, of Arrowsmith, Ill.; Charles Dilworth King, of Hillsboro, Ill.; Herbert Daniel Kistler, of Clinton, Mo.; Friedrich Emil Heinrich Krug, of St. Louis, Mo.; Gustav Adolf Lau, of St. Joseph, Mo.; Thomas Eliel Licklider, of Cuba, Mo.; John William Lindsay, of Orla, Mo.; Harry Lambert Logan, of Elba, Ill.; William Randolph Lovelace, of St. James, Mo.; Kenneth Kent McAlpine, of Vancouver, British Columbia; Melvin Edgar McCaskill, of Eminence, Mo.; John Snider McElvain, of Clarkston, Wash.; Charles Andrew McNeil, of Ottaville, Mo.; John William Macdonald, of Dubuque, Ia.; John Joseph Mahoney, M. D., of St. Louis, Mo.; Roy Earl Mason, of Albia, Ia.; J. Aaron Meiner, of Arrowsmith, Ill.; Louis August Theodore Meyer, of Hermann, Mo.; William Frank Meyer, of St. Louis, Mo.; James Malcom Miller, of West Lebanon, Ind.; Robert Mayberry Miller, of Carrollton, Mo.; Robert C. Montgomery, of Grand Forks, N. D.; Walter Scott Moonlight, of Leavenworth, Kas.; Edward Moore, of Bloomfield, Mo.; William Harrison Moore, of St. Louis, Mo.; Halford J. Morlan, of Fairfield, Ill.; John Charles Murphy, of Eldorado, Ill.; Lew Paul Murphy, of Omaha, Neb.; Robert Burdett Nyberg, of Harrisburg, Ill.; Isaac Hugh Odell, of Dillard, Mo.; Albin Monroe Painter, of Council Grove, Kas.; Henry Hiram Pantan, of Ponca City, Ok.; Joseph Keck Phipps, of Grant City, Mo.; Monteville Edward Poland, M. D., of Olney, Ill.; Walter Boscum Reeves, of Lone Oak, Tex.; William Hall Richardson, of Lexington, Ky.; Clarence Anderson Smith, of Liberal, Mo.; Silas Sterling Stahl, of Albion, Ill.; Edmund Felix Taake, of Florissant, Mo.; Walter Tallman, of Downs, Kas.; Arthur Edward Walters, of Springfield, Ill.; Enfer Clinton Webster, of Bible Grove, Ill.; Edward John Wehman, of Burlington, Ia.; Charles Alfred West, of Irving, Kas.; Arthur Rand Whitefort, of St. Elmo, Ill.; John Albert Wilkenes, of Leopold, Mo.; Charles Stewart Wilson, of Gibbs, Mo.; John Theodore Wolf, of St. Louis, Mo.; Harry Wood, of El Dara, Ill.; John Logan Young, of Fairfield, Ill.; Herbert Felix Taake, of Florissant, Mo. Post-graduate instruction: John J. Breaker, M. D.; Robert E. Donnell, M. D.; Gonzales Porter Dumanan, M. D.; David Milton Huffman, M. D.; David H. Simmons, M. D.

The Rôle of Sugar in Alimentation, By G. H. LEMOINE.

Sugar in Alimentation.—Lemoine cites the results of experiments made by several observers which indicate that saccharose has a high force producing power when taken by healthy persons undergoing fatigue. Other experiments on healthy individuals resulted in a loss of strength and dyspeptic troubles. The author seems to agree with Kaufmann that sugar is a material peculiarly adapted to furnish energy for immediate need.

April 22, 1905.

1. Spontaneous Improvement in a Case of Osteomalacia, By Professor BERGER.

2. Treatment of Fungoid Mycosis by Radiotherapy,

By J. BELOT.

1. **Spontaneous Amelioration in a Case of Osteomalacia.**—Berger reports the case of a man who at the age of 16 years developed a genu valgum for which osteotomy was performed in 1896. After the operation symptoms of osteomalacia appeared first in the right lower extremity, then in the left, then in the pelvis. In the following year, 1897, the upper limbs, the bones of the trunk, and of the head and face were involved. In 1898 the deformities which resulted had assumed an extreme degree. Each new extension of the disease was preceded by great pain, which was increased by the least touch or movement. The slightest muscular effort caused pain, accompanied by paroxysms, which resembled those of Jacksonian epilepsy. The general health was bad and he also suffered from vesical and renal lithiasis. Treatment seemed to be of no benefit, and he left the hospital in 1899 apparently near his end. In November, 1904, he reappeared. The same deformities were present, but his general condition was better and the bones were firm.

2. **Treatment of Fungoid Mycosis.**—Belot reports a severe case of fungoid mycosis in a woman, 39 years of age, which was successfully treated by exposure to the x rays.

LYON MEDICAL.

April 23, 1905.

1. Tracheobronchial Adenopathy with a Tuberculous Cavity in a Child, By RABOT and DE VILLIERS.

2. Epidemic of Measles with Gastrointestinal Complications, By GILLARD.

3. Formic Fever, By R. BELBEZE.

1. **Tracheobronchial Adenopathy.**—Rabot and de Villiers report a case in which a child, four years old, suffered from a frequent and violent cough, together with dysphagia. After having been under observation for about a month the child died. Autopsy revealed a chain of enlarged glands running along each side of the trachea, a large mass of glands below the bifurcation of the trachea, and a mass of glands which enveloped the two large bronchi from their origin to their entrance into the hilum pulmonalis. In the right lung was a cavity large enough to hold a walnut.

2. **Epidemic of Measles.**—Gillard gives brief histories of eighteen out of 25 cases of measles treated by him in the hospital at Tours, all of which were complicated by acute gastroenteritis of varying severity. The diarrhoea usually began two or three hours after the appearance of the eruption, the movements were green in color, of a peculiarly fetid odor, and varied in frequency, the average being twelve in twenty-four hours. Vomiting occurred in eight cases. Four patients died with symptoms of bronchopneumonia.

April 30, 1905.

1. The Horizontal Position in Treatment, By CH. VINAY.

2. A Rare Modification of the Urine in the Course of Typhoid Fever, By F. MOUISSET and S. BONNAMOUR.

1. **The Horizontal Position.**—Vinay speaks of the value of repose in the horizontal position as an important branch of the treatment of many diseases, among which he enumerates tuberculosis, psychoneuroses, circulatory disturbances, abdominal diseases, and phlebitis of the lower limb. He says there are only two objections advanced against this form of treatment, the danger of losing strength, which he considers an imaginary rather than a real objection, and the ennui a patient suffers from inaction.

2. **Rare Modification of the Urine in Typhoid Fever.**—Mouisset and Bonnamour report in very full detail the history of an attack of typhoid fever in a man, twenty-seven years of age, who had previously suffered from symptoms of cystitis. His urine was of normal color at the time of emission, but became blood red after exposure to the air. Albuminuria was constantly present. A probable diagnosis of alcaptonuria was made.

Diffuse Ecchymosis of the Face Following Compression of the Body, By F. LEJARS.

Ecchymosis of the Face Following Bodily Compression.—Lejars quotes extensively from the literature on this subject, but advances little if anything that is new.

RIFORMA MEDICA.

April 15, 1905.

1. Contribution to the Treatment of Intestinal Obstruction (*To be continued*), By FERDINANDO GANGOTANO.

2. Variations in Blood Pressure in the Lying and the Sitting Posture in Different Diseases,

By CARLO GENNARI.

3. Blepharoplasty with a Median Frontal Flap,

By EZIO MORETTI.

2. **Blood Pressure and the Position of the**

Body.—Gennari says that the two factors which cause lowering of the blood pressure when a person changes from the lying to the sitting or the erect position are the influence of gravity and the anæmia of the brain produced by this change of position. Gravity favors the circulation of the blood in most regions of the body when the patient is standing up, and thus favors the lowering of the blood pressure. In healthy persons the vasoconstriction occurring in sitting up is not always marked enough to counteract the influence of the anæmia, and thus the blood pressure is slightly lowered in the sitting position as compared to the prone or supine position. In debilitated persons, in neurasthenics, in certain forms of cardiac neurosis, in feeble persons with cardiac disease, in whom the vascular tonicity is diminished, the vasoconstriction is less marked, and the lowering of blood pressure on sitting up is more prominent. At the same time these persons show a dicrotic pulse in the sitting or standing position, which is due, according to Frey, to an increase in the frequency of the heart beats. On the other hand, in patients with high tension pulse, such as nephritics, in arteriosclerosis, in aortic insufficiency, etc., the pressure is not altered by sitting up, or standing, because the vasoconstriction is so great that it counteracts any tendency of gravity to lower the pressure. In such patients, therefore, the blood pressure is stable in either position. An interesting fact is, however, that the blood pressure is also stable in compensated heart disease, in which vasoconstriction is sufficient to counteract any other influence lowering the pressure, when the patient sits or stands after lying down. Morphine acts well in cardiac asthma, because it diminishes the vasoconstriction and lowers the blood pressure, contrary to the statements found in some text books. It must be given, however, in small doses.

BOSTON MEDICAL AND SURGICAL JOURNAL.

May 18, 1905.

1. The Satisfactory Prostatectomy,

By BENJAMIN TENNEY.

2. The Paramount Value of Localized Râles as a Sign of Incipient Phthisis,

By H. B. WHITNEY.

3. The Therapeutical Value of Some Digestive Preparations, and the Indications for the Use of Pepsin, in Diseases of the Stomach,

By RICHARD F. CHASE.

4. Infections of the Respiratory Tract with Influenza Bacilli and Other Organisms, Their Clinical and Pathological Similarity, and Confusion with Tuberculosis,

By FREDERICK T. LORD.

1. Prostatectomy.—Tenney favors prostatectomy by the suprapubic route for all cases except those in which there is a hard and fibrous prostate to be dealt with. The greatest objection to the suprapubic route is its greater mortality as compared with the perineal route. The author believes that this objection can be overcome by doing the operation in two stages: (1) The bladder first opened under local anæsthesia. (2) Some days later the prostate is enucleated under ether, through the vesical opening. Ten to twelve minutes will suffice for this. The author has operated twice by the method he proposes and in both cases the results were satisfactory.

2. Localized Râles.—Whitney concludes that the great and predominant value of localized râles in the diagnosis of incipient tuberculosis consists first, in their almost constant presence at a time when other local signs are absent or at most indefinite. Second, in their practically unmistakable character, thus differing widely from other signs which represent merely deviations from the normal. Third, in the fact that when occurring at an apex they are almost pathognomonic, other conditions which might produce them being exceedingly rare. While, therefore, other local signs are of great value, especially for the few experts who by long experience have learned their limitations and the frequent difficulty of interpretation, the presence of localized râles must ever remain the essential guide to early diagnosis for the rank and file of the profession.

3. Digestive Preparations.—Chase discusses the digestive value of the following preparations: (1) An essence pepsin, (2) an ess. pepsine, (3) a scale pepsin, (4) an elixir and tablets lactopeptine, (5) liquor diastas, (6) tablets pepsin and pancreatin, (7) tablets panzyme, (8) tablets peptenzyme, (9) an elixir of digestive ferments, (10) and papain. He concludes that they are practically useless for the object for which they are generally employed.

4. Infections of the Respiratory Tract.—Lord concludes: "(1) Of 186 non-tuberculous infections of the respiratory tract, observed clinically, for the most part, bronchitis: (a) A mixed infection with various organisms has been found in 120 (64 per cent.). (b) A comparatively pure infection with one group of organisms was found in 66 cases (36 per cent.). Of these pure infections those due to influenza bacilli comprise the largest group, with a smaller number of cases of pure infection with the pneumococcus, micrococcus catarrhalis, etc. (2) The pure infections, however, tend to become mixed, as the case progresses, and the observer must then remain in doubt, in the presence in the sputum of two or more groups of organisms, as to the relative importance of any one of the infecting agents. (3) In the clinical picture, the symptoms of onset, the course, and duration of the different pure infections, there seems to be nothing distinctive. They all tend to set up diffuse or local bronchitis and a varying degree of bronchopneumonia. The amount of prostration may be as great in one as in the other. (4) The pathological picture in cases of bronchopneumonia, due to the different organisms, likewise seems to be similar in the character of the exudate, its varying extent and intensity and the tendency, in a small proportion of cases, to end in permanent damage to the pulmonary substance. (5) These results of pulmonary invasion are not infrequently mistaken clinically for pulmonary tuberculosis. Of 85 cases of pneumonia, associated with various organisms, well marked localized pulmonary abscesses or induration, or both, were found in 8. No tuberculosis could be demonstrated at autopsy. (6) From the clinical resemblance of such cases to pulmonary tuberculosis, the presence of

the tubercle bacillus in the sputum must be regarded as the only infallible indication of this condition."

Fielding, By C. D. SPIVAK.
9. Immunity. Chapter XV (Concluded).

2. **The Treatment of Bone Cavities.**—Moore has had some very favorable results with von Mosetig's bone plug. Four of his recent cases are reported in detail. Briefly the method consists in completely filling bone cavities, resulting from operation, with a preparation of wax and iodoform. For success to be attained the following conditions must be fulfilled: The cavity must be sterile; it must be dry; all dead and diseased bone must be removed. The material for plugging consists of sixty parts iodoform, forty parts spermaceti and forty parts of oleum sesami. These ingredients are slowly heated to 100° C., and when allowed to cool form a soft solid which remains solid at the temperature of the body. For use it is heated to 50° C., being constantly stirred to keep the iodoform evenly distributed. At this temperature it can be poured into the cavity, where it immediately solidifies. This material does not act as a foreign body, nor does it act as a culture medium. It possesses the inhibitory and medicinal properties of iodoform without causing iodoform intoxication. Its physical properties are such that it is gradually absorbed and replaced by granulations and finally by new bone.

5. **Placenta Prævia.**—Holmes reaches the following conclusions: (1) Cæsarean section for placenta prævia lowers the foetal mortality 30 per cent. and raises the maternal death rate nearly threefold. Approximately the life of one mother is taken to save the uncertain existence of one baby. (2) Unquestionably some maternal deaths have been suppressed, as in Cæsarean sections for pelvic indications. (3) A rigid os is one of the rarest complications of placenta prævia. Undoubtedly most cases of so called rigid os are simply instances of cervixes unprepared for dilatation, or a misconception based on too brusque and rapid attempts to dilate or to extract. A true cicatricial cervix, and rigid cervixes of old primi-

paræ, may offer an indication for Cæsarean section in placenta prævia. (4) Pelvic contractions are indications for Cæsarean section in the presence of a prævia hæmorrhage; the pelvic contraction, not the prævia, is the determining indication. The earlier the interruption of gestation, *cæteris paribus*, the more may pelvic deformity be disregarded. (5) In general, the presence of a placenta prævia will not be recognized before hæmorrhages appear. (6) Cæsarean section for placenta prævia never will have so low a maternal mortality as when performed for a pelvic indication. Repeated examinations by the physician and his consultants must be made for diagnostic purposes; often a vaginal tampon must be introduced as a temporizing measure, at least until the woman may be transported to a hospital or preparations made at home for the laparotomy. The acute anæmia and finally the anatomical conditions post partum all render the operation a peculiarly dangerous one. (7) Placenta prævia cases appropriate for Cæsarean section generally will demand the procedure irrespective of the foetal condition, as the primal motive should be to save the mother. (8) Cæsarean section for placenta prævia should only be considered a *dernier ressort*. (9) If an abdominal operation is forced on the obstetrician, he should remove the uterus as a prophylactic against hæmorrhage and infection. (10) The profession should await the adjudication of the field for Cæsarean section in placenta prævia by obstetric authorities before resorting to the operation.

7. **Tuberculous Meningitis.**—Cheney discusses the difficulties which not infrequently arise in attempting to reach a diagnosis in suspected cases of tuberculous meningitis. The three cases he reports at length serve as illustrations to his theme.

MEDICAL RECORD.

May 20, 1905.

1. Cystoscopy and Renal Lavage, By FRANK M. JOHNSON.
2. The Disorders of the Nervous System Arising in the
Course of Chronic Nephritis,
By WILLIAM M. LESZYNSKY.
3. The Treatment of Eczema and Impetigo in Children,
By CHARLES W. ALLEN.
4. The Relation of the Medical Profession to the Restriction
of Tuberculosis, By S. P. WISE.
5. A Case of Hodgkin's Disease with But Slight Enlargement
of the Superficial Lymph Glands,
By HENRY FARNUM STOLL.
6. Ventral Decubitus as an Aid to Drainage for Diffuse
Purulent Peritonitis, By R. M. HARBIN.
7. Sanitation of the Summer Camp,
By HARVEY B. BASHORE.

1. **Cystoscopy.**—Johnson sets forth: (1) The indications demanding cystoscopy and renal lavage. (2) Rules it is wise to observe in preparing for cystoscopy. (3) Description of the *modus operandi*. (4) Difficulties likely to be encountered in the procedure. (5) Descriptive cases illustrating the beneficial effects of this method of treatment. The paper is fairly comprehensive and makes note of many practical points. Yet those who have had no experience with cystoscopy will be left in doubt on many points, and

those who have had some experience will probably find the article a trifle elementary.

2. **The Nervous System in Chronic Nephritis.**—Leszynsky's paper deals chiefly with the symptoms referable to disorders of the nervous system that are not infrequently observed in chronic nephritis. All of the following manifestations may be expressions of kidney insufficiency: Cephalic paræsthesia; headache in various degrees to true attacks of migraine; insomnia; numbness in the extremities; neuralgic pains in different parts of the body; vomiting; muscular twitching; monospasm or hemispasm to general epileptic convulsions; amaurosis; deafness; transitory attacks of aphasia; facial paralysis; paresis or paralysis of one extremity; hemiparesis, hemiplegia, or paraplegia; gradual or sudden coma; delirium; stupor; insanity; and permanent hemiplegia with or without aphasia. The author discusses most of them in detail and reports summaries of a few cases in order to emphasize the deplorable fact that sufficient attention is not paid to determining the significance of nervous symptoms. He has seen, in consultation, many cases of chronic nephritis with nervous manifestations which were incorrectly diagnosed by the attending physicians. In some of the cases the urine had not even been examined.

3. **Eczema and Impetigo.**—Allen makes the following original suggestions: (1) In eczema, as a general local measure, nothing equals a three to five per cent. solution of methylene blue. As soon as the solution has well dried upon the affected area it should be painted over with a thin layer of collodion. This should be repeated before the peeling collodion becomes itself a source of irritation. (2) Impetigo contagiosa is frequently, in the author's experience, associated with pediculosis capitis. He asserts his belief that the pediculi cause the condition. Treatment: First search for pediculi as possible disseminators or distributors and perpetrators of the affection. Remove crusts if necessary with potato flour poultice and apply a ten per cent. ammoniated mercury ointment, or wash with green soap solution and then with 1 to 1,000 bichloride of mercury. For small areas, paint with 50 per cent. ichthylol in water, or 5 to 10 per cent. ichthylol in collodion. Salol diluted will answer as a dusting powder, or apply 1 per cent. Beta naphthol with 5 per cent. boric acid in vaseline. As a rule, however, ointments are not so good as washes. For the scalp: 10 per cent. sulphur sublimite, $\frac{1}{2}$ to 1 per cent. red sulphide of mercury in vaseline. In infants at the breast, milder ointments, such as salicylic acid and bismuth or Lassar paste, spread on cheesecloth and applied, will serve. It is only in the rarest instances that any internal measures will be called for.

5. **Hodgkin's Disease.**—Stoll's case of Hodgkin's disease presented the following points of interest: The first symptoms of disease consisted in enlargement of the glands in the neck. These were thought to be tuberculous. Four years later acute symptoms associated with a skin eruption manifested themselves. The glandular enlargement

was always moderate. There were periodical attacks of abdominal tenderness and distention and alternating periods of pyrexia and apyrexia. The patient exhibited a marked anæmia. Before death occurred the glandular enlargements disappeared.

6. **Ventral Decubitus.**—Harbin advocates ventral decubitus in certain cases of peritonitis. He reports one case of appendicitis in which the abdominal wound was left open and the patient was periodically turned on his face. Drainage is said to have been extraordinarily good.

AMERICAN MEDICINE.

May 20, 1905.

1. Remarks on Mitral Stenosis, By FREDERICK P. HENRY.
2. Artificial Dilatation of the Cervix in Obstetrics, By RICHARD C. NORRIS.
3. Graves's Disease and Parathyroid Therapy, By JAMES J. WALSH.
4. The Surgical Treatment of Prolapsus Uteri, with Special Reference to the Operation of Colpectomy, By CHARLES GREENE CUMSTON.
5. Infection of the Urinary Tract by the Colon Bacillus, Simulating Uræmia, By JAMES RAE ARNEILL.
6. Intestinal Obstruction, By DYER F. TALLEY.
7. The New Asiatic Blood Fluke (Schistosoma Japonicum, 1904; Schistosoma Cattoi, 1905) of Man and Cats, By CHARLES WARDELL STILES.
8. The Hospital and the Dispensary in the Warfare Against Tuberculosis, By LAWRENCE F. FLICK.
9. A Working Programme for Associations for the Prevention of Tuberculosis—National, State, and Local, By EDWARD T. DEVINE.

1. **Mitral Stenosis.**—Henry follows Broadbent in his method of studying mitral stenosis, that is, he divides the disease into three stages. The diagnosis in the first stage is comparatively easy. At that time there is a presystolic murmur easily recognized as such by the fact that it is followed by the first and second sounds, both audible at the apex. The second stage is indicated by disappearance of the second sound at the apex, this being due to dilatation and hypertrophy of the right ventricle and feeble propulsion of blood into the aorta. The presystolic murmur continues. The onset of the third stage is marked by disappearance of the presystolic murmur and the establishment of signs of tricuspid regurgitation. The author calls attention to what he believes is another phase of mitral disease, and one to which no distinct allusion is made by authorities on diseases of the heart. It is an extreme arrhythmia which may persist without intermission for months or even for years. The clinical syndrome of these cases is the following: Marked anæmia, with somewhat dusky skin and cyanotic lips, a tendency to bronchial catarrh, marked periods of improvement, with little or no diminution of the arrhythmia, and no œdema whatever, or none until shortly before death. The author has notes of three such cases. In none could the slightest murmur be detected by any of a number of qualified observers. Autopsy proved that the diagnosis of mitral stenosis was correct.

2. **Dilatation of the Cervix.**—Norris reviews the different methods that have been proposed

for artificially dilating the cervix in the practice of obstetrics. He bases his remarks on his personal experience and not on a review of the literature. He concludes: "(1) The necessity for the induction of a premature labor by a method requiring less than twelve hours, is extremely rare. (2) The method most frequently employed, and most satisfactory in my experience, has been a combination of partial mechanical dilatation, followed immediately by the insertion of a bougie and an extraordinarily large Voorhees bag incompletely filled. (3) For the relatively rare cases in pregnancy or labor requiring accouchement forcé, the choice of rapid mechanical dilatation depends especially upon the character of the cervix, the general state of the patient, and the firm determination not to attempt too rapid dilatation. Bossi's or De Seigneux's instrument is cleaner, less tiresome, applicable to the same class of cases, and is not more dangerous than manual forcible dilatation. (4) Dührssen's vaginal section is a most valuable operation in the hands of an expert obstetric surgeon, and should be preferred to rapid metallic dilatation, except when conditions favorable to the latter are unmistakably present. (5) For the treatment of the gravest form of placenta prævia and of accidental hæmorrhage, Dührssen's hysterotomy, in the hands of an expert vaginal operator, should prove the best method of treatment ever offered."

3. Graves's Disease.—Walsh has treated a limited number of cases of Graves's disease with desiccated parathyroid glands. While he admits that his experience is too limited to warrant his drawing conclusions, yet he admits that personally he has lost all hope regarding the efficiency of this method of treatment.

4. Colpectomy.—Cumston has performed colpectomy three times within the past year and, up to the present, is satisfied with the operation. As advised by the author, colpectomy, for prolapse of the uterus, consists in excising the vagina, leaving the balance of the genital apparatus intact. The operation may be performed under cocaine and takes from twenty to twenty-five minutes.

MEDICAL NEWS.

May 20, 1905.

- Recent Advances in Our Knowledge of the Chemical Processes of Digestion, By LAFAYETTE B. MENDEL.
- Laennec and His Stethoscope, By C. N. B. CAMAC.
- Recent Advances in the Knowledge of the Movements and Innervation of the Alimentary Canal, By WALTER B. CANNON.
- A Case of Pneumococcus Infection of the Hip, By LEONARD W. ELY.
- Pneumonia.—Etiology and Epidemiology, By EDWARD F. WELLS.
- A Few Remarks on the Proper Cleansing of a Running Ear, By H. A. ALDERTON.
- 3. Movements and Innervation of the Alimentary Canal.**—Cannon considers in succession the mechanical activities of the different portions of the alimentary canal, that is to say of the œsophagus, stomach, small intestine, and large intestine, and of the sphincters. The paper covers

too many distinct topics to permit of its being abstracted.

4. Pneumococcus Infection of the Hip.—Ely reports the case of a child, four years old, who four weeks after a pneumonia developed an abscess of the left hip. The joint was laid open and the pus evacuated. This pus contained a microorganism that morphologically resembled the pneumococcus. The patient eventually died. No autopsy.

5. Pneumonia.—Wells holds that pneumonia is due to the pneumococcus, that this organism is present in the respiratory tract of many healthy people, that different strands of the coccus vary in virulence, and that such variations are due to environment. The author has observed that, in his experience at least, a person who has once had pneumonia will harbor the microorganism in his upper respiratory tract for all (?) time. This is probably the reason why the disease is on the increase. A table of the epidemics of pneumonia which have occurred between 1873 and 1903 is given. Some of the most notable outbreaks of the disease are briefly discussed.

ANNALS OF SURGERY.

May, 1905.

- Actinomycosis, By BEVAN.
- Cerebral Tumor, By OWENS.
- Retrosternal Accessory Thyroid Tumor, By COLLINS.
- Thorasthoracic Resection of the Lower End of the Esophagus, By MEYER.
- Gastroenterostomy and Pyloroplasty, By CANNON and BLAKE.
- Resection of the Middle Third of the Stomach for Carcinoma of the Greater Curvature, By SCUDDER.
- Some Surgical Considerations Pertaining to Gastric Dilatation, By FORD.
- Gunshot Wound of the Pancreas, By CONNELL.
- Hydrocele in the Female, By HALSTEAD and CLARK.
- Tuberculosis of the Testicle, By HAYNES.
- Rupture of the Tendon of the Biceps Flexor Cubiti, By KEEN.

1. Actinomycosis.—Bevan states that actinomycosis appears clinically under four different forms, from four different routes of infection: 1. Head and neck actinomycosis, with infection from mouth and pharynx, 50 per cent.; 2, chest actinomycosis through the respiratory tract, 15 to 20 per cent.; 3, abdominal actinomycosis with infection through the alimentary canal, or in the female through the genital tract, 20 to 25 per cent.; 4, actinomycosis of the skin, 2 per cent. The disease is not a rare one, its cause in man is the ray fungus, and this may enter through the mucosa, leaving no discernible lesion at the point of entrance. The primary lesion consists of granulation tissue and it extends in all directions, rarely by the lymphatics. The pyæmic form may result from breaking through a vein, multiple foci being established in the lungs, liver, spleen, etc. The prognosis is now much better than formerly, some cases recovering spontaneously. If surgical treatment is not possible, the prognosis is grave, but not always hopeless. If the diseased tissue can be reached it should be incised, scraped,

cauterized with nitrate of silver stick, the cavity packed with iodoform gauze, and iodide of potassium given internally in large doses. The x ray should subsequently be used.

5. Gastroenterostomy and Pyloroplasty.—

Cannon and Blake in summarizing their investigations observe that during digestion the cardiac end of the stomach slowly presses its contents to the pyloric end. At the latter end the food is churned about mixed with gastric juice and then forced, as chyme, into the intestine. During this process the stomach is shortened along its greater curvature, the pylorus then being the lowest point. Pressure within the abdomen is atmospheric pressure at any part of the alimentary canal, and depends on the weight of the overlying abdominal organs. If the canal is inactive the food is practically surrounded by water. The intragastric pressure is three or four times greater at the pyloric than at the cardiac end. Circulation of food from pylorus to duodenum and back to stomach through an anastomosis has often been observed without symptoms of the vicious circle, but such symptoms occur when there is a kink in the intestine distal to the anastomosis. Such kinks cannot be straightened by peristaltic activity. Food should be mixed with the secretions poured into the duodenum, thus neutralizing the acid chyme. Food which leaves the stomach by an artificial stoma is not mixed with these secretions. Jejunal ulcers following gastroenterostomy may be due to the presence of inorganic acid where it does not normally occur. An artificial stoma should therefore be as near the pylorus as possible, overeating should be avoided, and kinks should be prevented by attaching a narrow band of distal gut to the stomach for several centimetres beyond the stoma, favoring peristalsis. In pyloroplasty the objections to leaving the pylorus open are avoided. Too rapid exit of food through the pylorus is prevented by rhythmic segmentation of the food in the duodenum, replacing the functions of the pylorus, and tending to mix the food with the pancreatic juice and the bile.

6. Resection of the Middle Third of the Stomach for Carcinoma of the Greater Curvature.—

Scudder regards his case as important, because, 1, carcinoma of the greater curvature is unusual, 58 per cent., according to Fenwick, being pyloric, while only 2.8 per cent. involve the greater curvature; 2, the growth did not infiltrate the submucosa, as is usual with pyloric carcinoma; 3, it had attained considerable size without causing symptoms of gastric disturbance, neither the pyloric nor the cardiac ends of the stomach being involved; 4, the transverse colon was not involved; 5, an end to end anastomosis was done with an interrupted Connell suture; 6, the technics of the operation was facilitated by using clamps, according to the methods of Kocher, Hartmann, Mayo, and Moynihan.

7. Some Surgical Considerations Pertaining to Gastric Dilatation.—

Pond refers to dilatation as the result of a change which has taken place in

the elemental dynamics of digestion. The cause may have persisted for weeks or for years, and may be either mechanical or pathological. The mechanical cause may be within the stomach or without. The latter may consist in the pressure of a tumor or a misplaced organ, the former may consist of the scar of a corrosion or ulcer, spasmodic action of the pylorus, or carcinoma of the pylorus. The pathological causes may be atonic or atrophic. The symptoms are pain, either dull or acute according to the physical conditions, spasm of the pylorus, vomiting, etc. The operation of choice is gastroenterostomy, unless sufficient dilatation can be had by invagination. The simplest procedure that promises the greatest benefit to the patient is gastroplication. The objection to this operation has been that it leaves the mucous membrane in rugæ or in one large fold which permits the retention of fermenting contents of the stomach and causes recurrence of the symptoms. The author has so modified the operation that these objections are overcome.

8. Gunshot Wound of the Pancreas.—

Connell finds twenty recorded cases of this injury in nine of which there was recovery. Twelve were operated in with seven recoveries, the operation being performed from one to nine hours after the injury. There are no pathognomonic or even suggestive symptoms of injury of the pancreas in gunshot wounds of the abdomen. The probable course of the bullet is the chief guide. In wounds of the lesser omentum and the posterior wall of the stomach injury of the pancreas must be excluded before the abdomen is closed.

9. Hydrocele in the Female.—Halstead and Clark adopt Rignoli's classification of this lesion into five groups: 1, Diffuse hydrocele or hydrocele of the cellular tissue about the round ligament; 2, fluid in the canal of Nuck communicating with the free peritoneal cavity; 3, fluid in the vaginal process, not communicating with the peritoneal cavity, encysted hydrocele; 4, encysted hydrocele in the connective tissue about the round ligament; 5, fluid in the remains of an old hernial sac. A mistaken diagnosis of hernia is often made in this condition. If the possibility of an hydrocele is kept in mind the condition may be determined without operation. The presence of a tense, elastic, fluctuating swelling in the inguinal canal, or extending below the external ring, which has developed slowly, without known cause and gives no impulse on coughing will suggest hydrocele. Operation will reveal the presence of fluid in the sac. A hydrocele and a hernia may coexist. The safest diagnostic procedure is incision, and this is also the most rational therapeutical measure.

AMERICAN JOURNAL OF OBSTETRICS.

May, 1905.

1. The Technics of Abdominal and Vaginal Operations for the Relief of Fibromyomatous Tumors of the Uterus, By GOFFE.
2. The Care and Feeding of Premature Infants, By MORSE.
3. Sarcoma of the Uterus, with Remarks on Radiotherapy, By GRAD.
4. Persistent Mentoposterior Positions, By REED.

5. The Yeast Treatment of Acute and Chronic Vaginitis and Endocervicitis, By SCHILLER.
6. Vaginal Atresia Complicating Labor, By HIRST.
7. Secondary Metastatic Implantation of Carcinoma in the Vagina, By SCHUMANN.
8. Hæmatoma of the Ovary, By TATE.
9. The Uterine Curette, By KELLY.

1. The Technics of Operations for Relief of Uterine Fibroids.—Goffe narrates the history of such operations and describes his technics for abdominal hysterectomy as follows: The incision having been made the ovary and tube on one side are ligated, securing the ovarian artery. With the long end of the same ligature the broad ligament is again tied just above the uterine artery. A temporary ligature is then placed near the horn of the uterus. The broad ligament is then cut to the level of the lower ligature. This procedure is then repeated on the remaining broad ligament, the tumor is delivered, and the two wounds connected by anterior and posterior incisions upon the uterus. The peritonæum is then dissected back, anteriorly and posteriorly, and the uterine artery tied on either side. The tumor is then cut away at the level of the os internum, and the flaps stitched over the top of the stumps of the uterus and broad ligaments. He thinks the advantages of this technics are: 1, There is little hæmorrhage; 2, it is easy of execution; 3, it is generally applicable; 4, it requires less time than total extirpation; 5, convalescence is rapid and free from complications. He prefers to leave one or both ovaries if possible. With suppurative or cancer he prefers to remove the entire uterus. Myomectomy is usually preferable with women of the child-bearing age, when it is possible. The dangers either in myomectomy or hysterectomy are: 1, The possible injury to the bladder in making the abdominal incision; 2, injury to the bladder in dissecting it from the tumor or the uterus; 3, wounding the ureter while ligating the uterine artery; 4, wounding the ureter when it is in an abdominal or unusual position; 5, insufficiency of peritoneal tissue in the flaps, which cover the uterine stump; 6, wounding the intestine in separating adhesions.

2. The Care and Feeding of Premature Infants.—Morse states that there are few authentic cases of survival of infants born before the twenty-seventh week of pregnancy. A premature baby being an undeveloped baby must receive much greater care and attention than a mature infant. They lose heat rapidly and cannot bear low temperatures or exposure, they also offer very little resistance to infection. The first object with a premature baby is to keep it alive, the second is to develop its organism to the stage normally reached at term. Incubators maintain an even temperature, but none of them supplies a sufficient supply of pure fresh warm air. A substitute for an incubator is a padded crib or basket, which must be carefully protected from draughts. The food should be breast milk if possible, otherwise a modification of cow's milk. The older the infant the better the prognosis, and the prognosis is bad if the weight is under two pounds, but good if over four pounds. There may be no gain in

weight for many weeks, even though development is progressing favorably.

4. Persistent Mentoposterior Positions.—Reed reviews the history of this subject and reaches the following conclusions: 1, Engagement of the face in mentoposterior positions does occur, and the face may reach the pelvic floor without anterior rotation; 2, in most cases anterior rotation occurs spontaneously; 3, failure of the chin to rotate anteriorly indicates interference; 4, in entering the pelvis, the length of the child's neck may permit the head to sink well into the pelvis before the thorax is involved; 5, delivery of the unrotated chin is rare, but not impossible; 6, in 75 cases of impacted mentoposterior position the maternal mortality was 11.6 per cent., while it is 12 per cent. with placenta prævia under aseptic conditions; 7, the foetal mortality is about the same as in intra partum eclampsia; 8, the position should be corrected if rotation does not occur spontaneously; 9, version is the operation of election if the head is not engaged and manual flexion has failed; 10, version is contraindicated after engagement; 11, manual correction should always be attempted; 12, forceps should be used cautiously if at all; 13, if symphyseotomy is performed it should be while the child is vigorous enough to justify it; 14, asepsis will lower the general mortality figures.

8. Hæmatoma of the Ovary.—Tate has made a study of the literature of this subject and finds as a result that the follicular variety is the most common one. He does not believe the disease is a rare one, though the number of reported cases is not large. There may be a number of small hæmorrhages, or a single hæmorrhage may be so large as to destroy the ovarian stroma. The hæmatomata may vary in size from a hazel nut to a large orange. Pain is a symptom which is almost constantly present, and it may be severe if the ovary is fixed. In uncomplicated cases there is no fever. Schultze and Riedel have found hæmatomata in newly born infants. Winckel has found them as a result of petroleum burns, phosphorus poisoning, typhoid fever, tuberculosis, and heart failure. They may rupture and cause hæmatocele or peritonitis. They may be associated with abnormal menstruation, dysmenorrhœa, ovarian abscess, salpingitis, purpura, or epilepsy. They usually occur between the ages of 15 and 40 years, and in the left ovary more frequently than in the right.

THE PRACTITIONER

May, 1905.

1. Some Cases of Aneurysm, By GIBSON.
2. The Operative Treatment of Fracture of the Patella, By RIGBY.
3. Functional Insanity, By JONES.
4. Cessation of Epilepsy Consequent on Removal of Adenoids, By THOMSON.
5. The Dietetic Treatment of Dyspepsia, By HUTCHISON.
6. The Pathology and Treatment of Puerperal Eclampsia in the Light of Recent Work, By SIKES.
7. Some Aspects of the Serum Treatment of Diphtheria, By ROLLESTON.

8. A Review of Recent Investigations on the Physiology and Pathology of Secretory Tissues, By SHAW.
9. Recent Advances in Dermatology: 1, Tuberculosis Cutis, 2, The X Ray Treatment of Ringworm of the Scalp, By MACLEOD.

2. **The Operative Treatment of Fracture of the Patella.**—Rigby advocates the treatment of this condition by open operation, because, 1, there is a gain in time of about six months by this method of treatment; 2, the operation ensures sound bony union with a perfect functional result. The fragments of the patella may be wired or sutured together by the open or the subcutaneous operation. The arguments against the latter method of treatment are: 1, The wires must be removed in three or four weeks; 2, early passive movements cannot be thoroughly carried out; 3, the fractured surfaces cannot be freshened; 4, the blood and effusion in the joint remain untreated; 5, the torn tendinous expansions of the vasti are untreated; 6, exact coaptation of the fragments is out of the question. The open method practised by the author consists in: 1, Exposing the fragments by a vertical, transverse, or semilunar incision; 2, emptying the joint of blood clot, serum and torn tissue; 3, freshening the surfaces of the fragments; 4, passing wires through holes bored by a drill; 5, suturing lateral tears in the expansions of the quadriceps. Two silver wires should be passed, preferably through a semilunar incision. The wires should be buried, and in the author's experience do not cause irritation. Massage and passive movement of the joint should be begun in about twelve days, and two days later the patient should be allowed to get up. A table of twenty-one cases with clinical details concludes this article.

5. **The Dietetic Treatment of Dyspepsia.**—Hutchison considers two groups of dyspepsia cases: 1, Those in which there is organic lesion of the stomach; 2, purely functional cases. Digestible food for either group means that which is easily dissolved. The secretion of gastric juice is influenced by the chemical constituents of the meal and by the psychical condition of the patient. Of the organic diseases ulcer, dilatation, and acute and chronic gastritis are considered. In ulcer rest and unirritating food in small quantities are indicated. In dilatation the meals should be small, fermenting substances should be avoided, and the object should be to supply food which can be readily passed into the intestine. In gastritis rest and unirritating food are again the indications. In the functional dyspepsias there may be excess of acid, deficiency of acid with impaired motility, or flatulency. For the acid dyspepsia the author advises such foods as are most capable of absorbing and fixing hydrochloric acid, that is, a diet rich in proteids. Fats may also be taken freely. If the acid production is excessive milk alone may be indicated. If the acid secretion is deficient soups, salts, alcohol, and condiments should be taken freely while proteids should be avoided. In the cases in which flatulency is the chief symptom fermenting substances must be avoided, and the food should be as dry as possible. Hot water may be taken freely.

6. **The Pathology and Treatment of Puerperal Eclampsia in the Light of Recent Work.**—Sikes brings together a mass of evidence showing that the heart and liver, as well as the kidneys, are very often deranged with eclampsia. If albuminuria is absent the liver is the organ chiefly involved. Zweifel says, however, that albuminuria is always present with eclampsia. After delivery the albuminuria quickly disappears. Degeneration of the cardiac muscle is occasionally present, and results from the condition of the blood. After delivery the blood pressure falls, and this explains the occasional occurrence of stasis and thrombi. Some writers consider eclampsia a general intoxication, due to absorption of bacterial products from the placenta. Others ascribe it to defective metabolism on the part of the fœtus, the mother, or both. In general, it may be said it is due to non-elimination and deficient oxidation. As to treatment most writers agree that the blood pressure should be lowered. This is best accomplished by saline aperients or by these added to venesection. Chloroform and morphine serve a useful purpose as narcotics, but they sometimes merely postpone the convulsions. Diaphoresis is, of course, very useful, hot air baths, wet packs, etc., being indicated. The general principle should be to end the pregnancy as soon as possible after the fits have begun, by Cæsarean section if necessary. In other words, the active treatment is as a rule more successful than the expectant.

7. **Some Aspects of the Serum Treatment of Diphtheria.**—Rolleston speaks of severe pains at the site of the injection which may persist hours or days. If the dose is very large, there is usually no pain and the serum acts as a sedative, drowsiness being present two or three days. Hamatoma may develop at the site of the injection, also petechiæ. An eruption of the skin is of frequent occurrence, depending directly upon the size of the dose, and inversely upon the character of the attack. The principal varieties of eruption are: 1, The scarlatiniform; 2, the urticarial; 3, the circinate erythematous. Other forms are too infrequent to require notice. The eruption generally appears within a fortnight from the injection of the serum. It continues from a few hours to several days. Other symptoms are joint pains, adenitis, secondary eruptions, abscesses, hyperidrosis, etc. Albuminuria is often present, especially in very bad cases. Oliguria lasting two or three days with relative increase of urates and phosphates is a very common result. As a general rule the more marked the antitoxine reaction the better the prognosis.

BRITISH MEDICAL JOURNAL.

May 6, 1905.

1. Introduction to a Discussion on Influenza, By T. C. ALBUTT.
2. The Epidemiology of Influenza, By H. F. PARSONS.
3. A Record of a Year's (1904) Operations in Clarence Ward (Gynecological) of the Royal Victoria Hospital, Belfast, By J. W. BYERS and R. J. JOHNSTONE.

4. The Diazo Reaction in Tuberculosis.

By C. W. BUDDEN:

5. Tetany as a Complication of Gastric Tetany, with Notes of a Case, By A. TRIMBLE.

6. Preliminary Note Upon a Leucocytozoan of the Dog, By C. A. BENTLEY.

7. Acute Poisoning by a Single Castor Oil Seed, By A. G. GULLAN.

1, 2. Influenza.—Albutt states that influenza is apparently a very old disease, and it has been known of since the twelfth century. It seems to be endemic in Northern Central Asia, just as cholera is endemic on the Ganges. The outpost from which it is definitely traced to us is Bokhara, and it follows the three chief trade routes in Asia westwards in a very remarkable way. It travels in the time corresponding to the most rapid means of locomotion. Within the main flood of an epidemic there are subsidiary or secondary areas of intensity, due to the recrudescence of germs of the disease that may have become latent. The terrible suddenness of the disease is accounted for by the very short incubation, apparently sometimes even less than twenty-four hours, and nearly always less than forty-eight. The contagion is carried upon clothes, upon things as well as in human beings, although probably only for a very short time, perhaps a few days only. The disease is propagated in the sputum and spray from the respiratory tract; and those cases in which the respiratory tract is unaffected, are non-contagious. There is no doubt as to the specific character of the Pfeiffer bacillus—but of its habits, where it is generated, whence it comes, and how it usually survives, we are entirely ignorant. It may be a constant denizen of the mouth. Young children are not very susceptible, and except for the ear, do not suffer much from sequels. The malady in them passes off quickly, and convalescence is rapid. Five or six months' immunization is usually conferred by an attack, even on the most susceptible; twelve months is the more usual respite. As regards the morbid anatomy the lesions are inflammations of an erysipelatous type. If there be lobar inflammation of the lung, it is almost always associated with lobular patches, and is very seldom confined to one lung. In influenzal pneumonia the sputum is mucous or mucopurulent, and not rusty. Like pulmonary tuberculosis influenza may excavate the lung; the patient may be badly wrecked yet ultimately recover. It is a most calamitous event when influenza falls upon a lung already tuberculous. Influenzal pleuritic effusions do badly, and pericardial still worse—also empyemas, where streptococci are usually also present. The heart may get into a very perilous condition, yet post mortem of the changes may be very slight, the danger lying in the nervous endowment of the heart rather than in the muscular fibre. The author lays great stress from a diagnostic point of view, on the extreme suddenness of the onset—ordinary colds creep on. The prostrating effect upon the nervomuscular system is frequently terrific. In convalescence the malaise very often departs as suddenly as it comes on—a brusque recovery

from a protracted convalescence. The temperature is not high or very prolonged, but often falls considerably below normal. The disease may be divided into four forms—respiratory, nervous, gastrointestinal, and continuous. Contrary to the general rule in almost all acute febrile diseases, the urine in influenza is not high colored nor lateritious. Convalescence is terribly slow and its duration is in no proportion to the attack. Neuritic and paralytic attacks are not so frequent as formerly. Angina pectoris and phlebitis are not uncommon. Minor and tedious perversions of the heart's action are very abundant. Murmurs are not the rule. Chloroform should be avoided. Dyspepsia persists for a very long time, and also the obstinate recurrence of profuse paroxysmal sweats. The patient should go to bed the moment influenza is suspected, and remain there until the acute phase is past. The disease is very much shortened by a non-toxic diet. Parsons, in discussing the epidemiology of the disease, tells us that it spreads by personal infection. The striking distance of influenza is longer than in some other diseases—the bacillus may be carried several feet through the air by the acts of coughing, sneezing, etc. The outbreak of the disease cannot be ascribed to any particular kind of weather, but the epidemics are more fatal in weather when the temperature is below the average. It is more fatal in the later periods of life, and in agricultural and residential districts. Bad sanitary conditions, such as favor the prevalence of diarrhoea and typhoid fever, seem in some way inimical to influenza.

4. Diazo Reaction in Tuberculosis.—Budden from his observations concludes that the diazo reaction is not of any value in the prognosis of chronic tuberculosis. The positive cases have died, but they were the cases without hope. The appearance of the reaction corresponds with the exacerbations of the tuberculous process, but it follows the onset of the graver symptoms, and though it disappears with improvement, such disappearance again follows the suspension of the alarming signs; while again it may disappear because the patient is growing weaker. It is probable that every fatal case of tuberculosis will yield the reaction at some period of its course; we cannot say any case is negative unless it has been tested continuously for long periods. Of seventeen cases which were negative and yet proved fatal, six succumbed to intercurrent diseases. The author followed the reaction in 3,000 cases. Of these, 600 were healthy individuals, and not one yielded a positive reaction. In tuberculosis, 96 out of 672 were positive; measles, 18 out of 25; typhoid fever, 17 out of 21; typhus, 5 out of 5; pneumonia, 5 out of 57; and puerperal septicæmia, 4 out of 4. In the remaining cases, comprising almost every acute malady of common occurrence, the reaction was uniformly negative.

5. Tetany.—Trimble reports a fatal case of gastric dilatation complicated with tetany occurring in a man aged forty-five years, in which death took place on the seventh day. Points of interest in the case were: 1. Hiccough which was

persistent and constant towards the end, resisting all treatment. 2. The peculiar mental condition. When the first paroxysm of tetany passed off the patient's mind was perfectly clear, but gradually he became more and more delirious and incoherent until the stage of complete coma was reached on the seventh day. The pathology of tetany in gastric dilatation might be pictured thus: The stomach, narrowed at its pyloric end by the cicatrization of an old ulcer, is gradually dilated into a mere bag, with scarcely any digestive power, and thus becomes a suitable nidus for fermentative toxins which gradually become absorbed into the system, producing a condition of nervous irritability both directly and reflexly—directly by acting on the delicate sensory nerve ends of the extremities, and reflexly as a result of this on the motor nerve cells in the cord producing the characteristic spasm of the extremities, upon any determining cause sufficient to upset the unstable equilibrium of the nervous system. Lavage has fallen into disrepute as a mode of treatment. If the patient survives the attack, Robson strongly recommends operation for the relief of the pyloric stenosis, which is the primary cause of the disease, and is present in about 92 per cent. of the cases. This is the only treatment which has up to the present given any hopeful results.

9. A Case of Hæmatoma of the Ovary Simulating an
Attack of Appendicitis, By H. W. WILSON.

2. **Nutrition.**—Allchin, in the second of his Lumleian lectures, considers in detail the changes undergone during digestion and subsequent absorption of the different alimentary principles. He finds that the general result of the hydrolysis is to convert the normal substances into bodies somewhat less complex in character, but becoming at the same time more diffusible. Such changes are destructive or analytic in nature. Inasmuch, however, as it is most certain that the materials as presented for assimilation by the bioplasm are not (with few exceptions, chiefly among the inorganic ingesta) in the form in which they occur in the food, nor even as they are after undergoing digestion in the alimentary canal, some further changes must be undergone by them, somewhere between the surface of the gastrointestinal epithelium and the living cell into which they will be incorporated, and these changes for the most part are of a synthetic character. The

changes which take place in the alimentary canal are well understood and readily imitated in the laboratory. But those changes which commence with the gastrointestinal epithelium, though probably of the same nature, are not so readily imitated. With the absorption of the digested material the direct influence of living protoplasm is for the first time brought to bear on the aliment. At the same time it is admitted that the digestive processes themselves are effected by the products of bioplastic activity—viz., the ferments—and it may well be that after all the subsequent elaboration of the nutriment is effected by similar agencies. The intestinal epithelial cells, to which formerly was attributed the sole function of permitting the passage of the diffusible gastrointestinal contents, are possessed of powers of high metabolic value apart even from those scarcely less important which are concerned with the production of such a stimulus to pancreatic secretion as secretion or the actual formation of a special fluid, the succus entericus, with its specific powers. These tissue elements break up the proteids into simpler substances, and reform the fats, which in order to be absorbed have been broken up into acids and glycerin.

4. **Blood in Meningitis.**—Curl has studied the blood changes which occur in meningitis in children, and concludes as follows: 1. The red corpuscles are usually present in normal or increased numbers. 2. The majority of cases show no leucocytosis. This may be explained in four possible ways: (a) The tubercle bacillus may enter the body and exert its characteristic effects without producing leucocytosis. (b) There may be no leucocytosis because the irritation of the tissues by the tubercle bacillus and its toxins is either too mild in nature or too severe. (c) The tissues being constantly exposed to the toxins of the tubercle bacillus may in time come to be endowed with a relative immunity to them and therefore will no longer exhibit any reaction on further exposure to the irritant. (d) The most active and powerful toxine produced by the tubercle bacillus may arise in the body of the bacillus itself, but owing to the nature of the bacterial cell is unable to escape in sufficient quantities to exert its irritant action on the body tissues. 3. The eosinophile cells are reduced in number. 4. The large lymphocytes and transitional cells are generally present in increased proportions.

5. **Trichromatic Vision.**—Edridge-Green reports two cases of trichromatic vision, using the term "trichromatic" as a statement of the fact that persons having this vision see only three colors in the bright spectrum, whilst the normal sighted see six and may, therefore, be designated as hexachromatic.

6. **Eosinophiles.**—Cunnington, from his observations on the blood, concludes that the granulations of the eosinophile leucocytes are antitoxic or bactericidal in nature, that they are discharged into the blood at the onset of an infection, and that after the toxins have been neutralized the blood becomes richer in antibodies. When this cell is present in the blood to the extent of one

per cent. or more, it is almost certain that there is no active suppuration taking place. This cell may be quite absent, although there is no abscess.

EDINBURGH MEDICAL JOURNAL.

May, 1905.

1. Some of the Uses of Oxydized Pyrogallic Acid (Pyraloxin) in Dermatology, By JAMIESON.
2. Insanity, By MACPHERSON.
3. The Prognosis and Treatment of Early Pulmonary Tuberculosis, By PRICE.
4. Poisoning in Scotland to the Year 1625, By STEWART.
5. Chronic Cyanosis, with Polycythæmia and Enlarged Spleen, By BEGG.

2. **Insanity.**—Macpherson thinks that in the present state of our knowledge a clinical classification of insanity is the only possible one, for pathology is not yet sufficiently advanced to afford a basis of division, nor is there any hope that in the immediate future our knowledge of the minute anatomy of the nervous system will be sufficient to form the basis for a classification. Starting with mental defect as his first class, he proceeds to confusional insanity as his second. The delirium of fevers is the type of this class. Other forms are alcoholism, puerperal insanity, dementia præcox, and general paralysis. Delirium, confusion, and stupor are the prominent symptoms. In all forms of confusional insanity there is the effect of a poison on the nervous system, especially the brain, the cortex being more or less severely injured. The recurrent insanities are mania, melancholia, the neuroses, obsessions and impulses, and paranoia. They are degenerative in origin, occurring in those who have inherited a neuroathic constitution. They occur in early adult life, they manifest emotional disturbance, and have a tendency to recur. Dementia forms the next class and implies a weakening of the expression or ordinary mental processes. It is usually the result of confusional insanity. Finally there are presenile and senile forms of insanity. Climacteric melancholia is one of the well known forms. Late in life, in senile insanity, the symptoms are loss of memory with emotional disturbance, illusions, hallucinations, or vague systematized delusions.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of April 12, 1905.

The President, Dr. JAMES M. ANDERS, in the chair.

Resection of the Elbow.—Dr. G. G. DAVIS exhibited a patient, a girl of thirteen, who at the age of seven years had sustained an injury of the elbow resulting in stiffness. Two years ago there were pain and discharge. On account of the excessive pain the ulnar nerve was freed, but the pain continued. Later Dr. Davis saw the case and a skiagraph showed ankylosis of the bones of the forearm with those of the arm. He did a

resection, and the result was ability to do light house work and to use the arm in sewing. The apparatus used to secure motion was also shown. This was an attachment to the forearm with a light weight allowed to hang at the back.

Dr. HENRY E. WETHERILL thought the light weight employed by Dr. Davis an improvement over the heavy one of a flat iron sometimes used to maintain motion.

An Auscultatory Device.—Dr. WETHERILL showed a small device which he had had cut from wood, upon the plan of the stethoscope, for measuring the amplification of sound of the aortic and other valves. The instrument was flutelike in appearance. One end was to be placed in the ear, and the fingers were to be taken off of the holes one after another until the sound was not heard. The roaring, a troublesome feature of the ordinary stethoscope, was avoided by the use of a pinhole. The instrument had proved itself of practical value.

An Encysted Calculus Removed by Suprapubic Cystotomy, with Skiagraph.—Dr. EDMUND W. HOLMES reported a case of encysted calculus removed by suprapubic cystotomy in a patient aged forty-five presenting the classical symptoms of stone in the urinary bladder. Under ethyl chloride as a general anæsthetic the bladder was washed out with a Bigelow evacuator, and a careful systematic search made with a sound. Dr. W. T. Menges, of the Jefferson Hospital, made a shadowgraph and reported the presence of a small calculus. Suprapubic section revealed the calculus encysted in the lower posterior wall of the bladder. The specimen was found to correspond almost exactly in size to the black spot on the picture. Its complete encapsulation had caused failure of detection by the sound.

The patient had an ankylosis of the hip joint due to a pathological condition of childhood. The thickening was shown in the x ray picture.

Enlarged Prostate.—Dr. HOLMES further reported a case of enlarged prostate removed by perineal prostatectomy in a man aged seventy-two. The first attack of retention of urine had occurred five years ago, requiring catheterism for about two weeks. In August, 1904, there was a second attack, during which catheterism became difficult and painful. Dr. Holmes saw the case in consultation, and subsequently did a perineal prostatectomy, which operation occupied thirty-one minutes, including the anæsthetization. Later the patient refused catheterism, and the fistula remained in the perinæum (eight months after the operation). The man now had complete control over urination, the urine passing out altogether through the opening in the perinæum. He was in good health and conducting a successful business.

Posterior Gastrojejunostomy for Benign Stenosis of the Stomach.—Dr. WILLIAM H. MORRISON presented the following case: A man, aged forty-four years, came under observation in August, 1904, with evidences of almost complete stenosis of the pylorus and great dilatation of the stomach. During the previous four years there had been

three attacks of gastric hæmorrhage. He vomited almost daily, and in the vomited matters were frequently found articles that had been eaten one or two days previously. There were great weakness and emaciation. No tumor could be detected.

Posterior gastrojejunostomy with the Murphy button was done on November 4, 1904. Recovery from the operation was rapid and complete. All symptoms of digestive disorder disappeared and the patient was able to eat and digest all varieties of food. Strength and flesh were rapidly regained, and in four months the weight increased forty pounds. The button was not found.

Dr. WILLIAM L. RODMAN regarded the case as a proper one for gastrojejunostomy, and agreed with Dr. Holmes that the Murphy button still had its place in gastric surgery. The operation of anterior gastrojejunostomy, he believed, was passing out of use.

Cerebrospinal Fever, or Epidemic Cerebrospinal Meningitis.—Dr. JAMES C. WILSON, in this paper, called attention to the importance of the recent epidemics of the disease in New York and elsewhere in this country. The affection, he said, tended to become naturalized and prevail in the form of sporadic cases in those localities in which epidemics had occurred. He quoted the statement of Councilman that the *Diplococcus intracellularis meningitidis* was a feeble organism outside of the human body, had little resisting power to light and drying, and was incapable of a saprophytic existence so far as was known. It was probable therefore that the existence of the disease was maintained by the sporadic cases.

Dr. WILSON considered the symptomatology and diagnosis of the disease at considerable length, and called attention to a form of it not generally recognized in which there were, early in the attack, symptoms of acute nephritis. As prophylactic measures, isolation of the patient and thorough disinfection were recommended. The old treatment with opium or its derivatives was described, and some of the more recent therapeutic procedures, namely, the intraspinal injection of a 1 per cent. solution of lysol and the use of diphtheria antitoxine serum, were spoken of as under investigation at the present time.

Dr. JAMES TYSON said that his experience with cerebrospinal fever during the past winter had been confined to a few cases seen at the Pennsylvania Hospital in the hands of his colleagues. He recalled the epidemic during which Dr. Stillé's classical paper was written. There was a tradition, he said, that the epidemic which occurred during the War of the Rebellion was introduced by returning soldiers, and there was also a popular belief that the cause of the disease lay in mouldy hay. Since that time cerebrospinal fever had never entirely disappeared from Philadelphia. The most important question was that of its contagiousness. While Dr. Wilson had adduced remarkable cases, apparently dependent one upon another, he recalled the paper by Dr. A. C. Abbott before the Philosophical Society, citing cases largely isolated and occurring one after another in the most remote districts. Dr. Tyson believed

that the disease was to a certain extent contagious, but not virulently so as compared with typhoid fever.

He was favorably inclined toward the submer-sion treatment of the paralytic phenomena. In a case of almost total paralysis this treatment, in conjunction with massage, had brought about almost entire recovery. The principle of the treatment, he explained, was to place the patient in the bath of warm water and to encourage voluntary motion, which was accomplished with greater facility than in the open air.

Book Notices.

Clinical Hematology. A Practical Guide to the Examination of the Blood with Reference to Diagnosis. By JOHN C. DACOSTA, JR., M. D., Demonstrator of Clinical Medicine, Jefferson Medical College. Second Edition, Revised and Enlarged. Containing 9 full page Colored Plates, 3 Charts, and 64 Other Illustrations. Philadelphia: P. Blakiston's Son & Co., 1905. Pp. 591. (\$5.00.)

In the three years that have passed since the publication of the first edition of this work there have been important advances in hæmatology. By the study of the blood, trypanosomiasis, kola-azar, Montana fever, and cyanotic polycythæmia have been identified as clinical entities; the blood changes incident to chloroma, hydatid infection, multiple periostitis, pancreatitis, variola, arthritis deformans, sprue, leucæmia, burns, and x ray therapy have been investigated; and the bacteriæmic character of Malta fever and scarlet fever has been proved. The literature of the subject has been gleaned carefully, and all advances of any importance have been incorporated in this volume. The author has also made a large number of original investigations in his hospital work, and has summarized the results of his research. No reference is made to the presence of large quantities of cholin in the blood in general paresis and other neuroses in which there is disintegration of nervous tissue. This symptom is likely to be of diagnostic value.

The aim of the book is to interpret the state of the blood as a rational aid to diagnosis, and the advance in hæmatology has made a working knowledge of the subject indispensable to every practitioner who would keep in touch with medical progress. The illustrations are excellent, and the colored plates are particularly fine.

Miscellany.

Dr. Osler's Farewell Speech in New York.—The last public address made in New York by Dr. Osler before leaving for England was at the annual dinner of the Society of McGill Graduates of New York, at the Imperial Hotel on May 4th. In the course of his address, Dr. Osler said:

"You should always remember your old alma mater, and always strive to do something for her. He who leads a worthy life and who rises to good standing in the line to which his life work is de-

voted does something for his university. And in remembering your university you who are resident here should not be unmindful of the country which gives you the opportunities. A great university requires a certain maturity. There must be a leisure class in the making of a great university. Too much teaching must not be required of the professors. The best work in a university is done by a sort of academic loafer. It does not matter if the professor meets the students but little. In fact, it is better if he does not meet them at all. The professor is there not merely to teach, but to think, and he can't think hard and teach hard at the same time. One of the best professors at Johns Hopkins, Professor Rowland, rarely met the students. He met them as little as possible. He loathed to meet them. But see him in the laboratory with a group of the higher students about him, and his presence was an inspiration. There are many of McGill's sons in this country, and they have many of them made their mark here. We have literally taken the stranger within our gates. Talk about annexing Canada! Why should Canada be annexed when Canadians are annexing so much themselves? But I am sorry so many Canadians come here. I am sorry for the cause of it. It is a delicate matter with you all here to speak of the cause of it. But *cherchez la femme*. And there is one thing in particular I want to speak about. I want you to stop the Canadian girls from coming over here—stop bringing the girls over here. It is a great shame the way they are coming. I met a young man from St. Thomas not long ago. He came to see me in Baltimore. He was a fresh faced, vigorous looking young man, but he seemed rather dejected. I said to him, 'You ought to be happy and contented. You are seven or eight and twenty, you ought to be married and settled and happy.' 'That's just it,' he replied, 'she's over here. That's why I came over here myself—came to see her. I only took you in on my way back.' You must urge the girls to stay at home. You ought to. I learn that the birth rate in Ontario is falling off—is rapidly diminishing."

"You mean Quebec," interrupted a voice from the chairman's table.

"Not a bit of it," continued Dr. Osler, amid prolonged laughter. "I mean Ontario. I don't mean Quebec. You can't diminish the birth rate up there." [Long laughter and applause.]

Apropos of the Quebec Provincial Birth Rate.

—It appears that in the year 1890 the late Honorable H. Mercier, then Prime Minister of the Province, had a law passed by the Provincial legislature granting one hundred acres of the public lands to each father and mother of twelve living children, and last year a return was made to the house of those who had taken advantage of this act. This return shows that there were more than 3,400 families of twelve living children in the Province, while some boasted of 17, 18, 19, and one even ran up to 23.

According to the last report of the Provincial compiler of vital statistics, that is to say, for 1903, 60,419 births were registered, which gives a birth rate of 36.75 per 1,000 of the population.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended May 20, 1905:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Dist. of Columbia—Washington.	May 6-13.	6	2
Florida—Jacksonville.	May 6-13.	12	1
Illinois—Chicago.	May 6-13.	33	1
Illinois—Galesburg.	May 6-13.	1	1
Louisiana—New Orleans.	Apr. 29-May 13.	23	1
Two cases imported			
Massachusetts—Lowell.	May 6-13.	2	2
Massachusetts—Quincy.	Apr. 29-May 6.	2	2
Michigan—Detroit.	Apr. 29-May 13.	5	1
Michigan—Grand Rapids.	May 6-13.	15	1
Missouri—St. Louis.	May 6-13.	12	1
New Hampshire.	Apr. 29-May 13.	3	1
New York—New York.	May 6-13.	6	1
Ohio—Cincinnati.	Apr. 28-May 5.	8	1
Pennsylvania—Lebanon.	May 6-13.	1	1
Pennsylvania—York.	Apr. 29-May 13.	29	1
Rhode Island—Providence.	May 6-13.	1	1
South Carolina—Charleston.	Apr. 29-May 6.	2	1
South Carolina—Greenville.	Apr. 20-May 6.	4	1
Tennessee—Memphis.	Apr. 20-May 13.	12	1
Tennessee—Nashville.	May 6-13.	2	1
Wisconsin—Milwaukee.	Apr. 29-May 13.	10	1
Smallpox—Insular.			
Philippine Islands—Manila.	Mar. 11-Apr. 8.	3	1
Smallpox—Foreign.			
Belgium—Ghent.	Mar. 25-Apr. 1.	1	1
China—Nanking.	Apr. 8.	Present.	1
China—Shanghai.	Mar. 11-Apr. 8.	3 among foreigners, 14 deaths natives.	2
Ecuador—Guayaquil.	Apr. 18-27.	4	3
Great Britain—Edinburgh.	Apr. 15-22.	1	1

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending May 17, 1905:

GASSAWAY, J. M., Surgeon. Granted leave of absence for four days from May 23rd.

LIGHT, S. D. W., Acting Assistant Surgeon. Granted leave of absence for six days from May 2nd.

MALONY, J., Acting Assistant Surgeon. Granted leave of absence for thirty days from July 1st.

GIBSON, F. L., Pharmacist. Department letter granting Pharmacist Gibson leave of absence for twelve days from May 6, 1905, revoked.

Board Convened.

Board convened to meet at Baltimore, Maryland, May 12, 1905, for the physical examination of cadets, Revenue Cutter Service. Detail for the board—Surgeon L. L. WILLIAMS, chairman. Assistant Surgeon W. H. FROST, recorder.

Appointment.

Dr. SIMON P. BROOKS appointed acting assistant surgeon for duty at Memphis, Tenn.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending May 30, 1905:

ADAIR, GEORGE W., Colonel and Assistant Surgeon General. Promoted to the rank of colonel and assistant surgeon general, to date from April 6, 1905.

BRUNS, E. H., First Lieutenant and Assistant Surgeon. Ordered to proceed from Brockville, Ind., and report to the commanding general of the Department of California, for duty at Sequoia, or National Park, Cal.

COLE, CLARENCE L., First Lieutenant and Assistant Surgeon. Appointed first lieutenant and assistant surgeon, to rank from May 10, 1905.

DE LOFFRE, SAMUEL M., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Assiniboine, Mont., and ordered to Fort Schuyler, N. Y., for duty.

DUNCAN, WILLIAM A., First Lieutenant and Assistant Surgeon. Recently appointed, and ordered to Fort Leavenworth, Kan., for temporary duty.

EKWUNZEL, GEORGE M., First Lieutenant and Assistant Surgeon. Detailed a member of a board of medical officers to meet at West Point, N. Y., June 1, 1905, for the physical examination of the cadets of the graduating class at the United States Military Academy, and such other cadets and such candidates for admission to the academy as may be ordered to appear before it.

GRAY, WILLIAM W., Lieutenant Colonel and Deputy Surgeon General. Promoted to the rank of lieutenant colonel and deputy surgeon general, to date from April 6, 1905.

GIBNER, HERBERT C., First Lieutenant and Assistant Surgeon. Ordered to proceed from Bridgeport, Conn., and report to the commanding general of the Department of California, for duty at Sequoia, or National Park, Cal.

HALL, JOHN D., Colonel and Assistant Surgeon General. Granted thirty days' leave of absence.

KEAN, J. R., Major and Surgeon. Ordered to proceed to Panama to confer with Colonel Gorgas, Assistant Surgeon General, pertaining to the purchase of medical supplies for the Department of Health of the Government of the Isthmian Zone.

MASON, CHARLES F., Major and Surgeon. Detailed a member of a board of medical officers to meet at West Point, N. Y., June 1, 1905, for the physical examination of the cadets of the graduating class at the United States Military Academy, and such other cadets and such candidates for admission to the academy as may be ordered to appear before it.

MOSELEY, E. B., Lieutenant Colonel and Deputy Surgeon General. Ordered to make medical and sanitary inspection of several posts in the Department of Colorado.

PALMER, FRED W., First Lieutenant and Assistant Surgeon. Left the United States Rifle Range, Arcadia, Mo., on ten days' leave of absence.

RHOADS, THOMAS L., First Lieutenant and Assistant Surgeon. Detailed a member of a board of medical officers to meet at West Point, N. Y., June 1, 1905, for the physical examination of the cadets of the graduating

class at the United States Military Academy, and such other cadets and such candidates for admission to the academy as may be ordered to appear before it.

WOODSON, R. S., Major and Surgeon. Promoted to the rank of major and surgeon, to date from April 6, 1905.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 20, 1905:

BERTOLETTE, D. N., Medical Director. Commissioned a medical director, with the rank of captain, from April 5, 1905.

BEYER, H. G., Medical Inspector. Commissioned a medical inspector, with the rank of commander, from April 5, 1905.

DE VALIN, C. M., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from January 31, 1903.

DUNN, H. A., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, with the rank of lieutenant, from June 7, 1904.

GUEST, M. S., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from March 3, 1903.

HOEN, W. S., Assistant Surgeon. Detached from the *Oregon* and ordered home.

STALNAKER, P. R., Assistant Surgeon. Commissioned an assistant surgeon, with the rank of lieutenant (junior grade), from May 3, 1905.

TOLFREE, H. M., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, with the rank of lieutenant, from June 14, 1904.

VICKERY, E. A., Assistant Surgeon. Detached from the *Southerly* and ordered to the *Franklin*.

WARNER, R. A., Assistant Surgeon. Commissioned an assistant surgeon, with the rank of lieutenant (junior grade), from May 3, 1905.

WEBB, U. R., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, with the rank of lieutenant, from October 11, 1904.

WILSON, H. D., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from March 31, 1903.

Births, Marriages, and Deaths.

Married.

COTTON—ROSSITER.—In Manila, Philippine Islands, on Wednesday, April 26th, Dr. Cotton, of New York, and Miss Florence Rossiter.

DONCASTER—BOOTH.—In Cincinnati, Ohio, on Tuesday, May 9th, Mr. James W. Doncaster and Dr. Georgia R. Booth.

MEANS—WOLFE.—In Philadelphia, on Tuesday, May 16th, Dr. T. K. Means and Miss Anna Marie Wolfe.

SMITH—CANTERBURY.—In Boston, Massachusetts, on Monday, April 3rd, Dr. Winfield Smith and Miss Gertrude Canterbury.

Died.

BAYNE.—In Washington, D. C., on Wednesday, May 17th, Dr. John W. Bayne, in the sixtieth year of his age.

DEANE.—In Washington, D. C., Saturday, May 6th, Dr. Julian W. Deane.

FARIS.—In Hickman, Kentucky, on Friday, May 12th, Dr. Alexander Faris, in the sixty-sixth year of his age.

HYSELL.—In Pomeroy, Ohio, on Thursday, May 11th, Dr. James H. Hysell, in the sixty-eighth year of his age.

LOWENTHAL.—In Hoboken, New Jersey, on Sunday, May 14th, Dr. Ernst J. Lowenthal, in the ninety-second year of his age.

ROGERS.—In Paterson, New Jersey, on Sunday, May 14th, Dr. Alexander W. Rogers, in the ninety-first year of his age.

TAYLOR.—In Brooklyn, N. Y., on Tuesday, May 9th, Dr. Walter L. Taylor, in the eighty-sixth year of his age.

THE MEDICAL AND SURGICAL TREATMENT OF GASTRIC ULCER.*

By BEVERLEY ROBINSON, M. D.,

NEW YORK.

In a rather lengthy paper entitled Problems Relating to Simple Ulcer of the Stomach which I read at a meeting of the New York Clinical Society last October, and which subsequently appeared in the *New York Medical Record*, my views on this subject were fully set forth, and at the very outset I would say that I have now but little new or different to offer. That paper was largely based upon my personal experience in the treatment of ulcer of the stomach, and, among others, included twenty-nine cases the histories of which had been obtained for me by Dr. J. Emil Traub, of this city, from the records of St. Luke's Hospital for the past twenty years.

Theoretically, with past experience to guide us, the treatment of gastric ulcer belongs essentially to the physician, and there are few diseases, even today, that have more direct and positive interest for him than simple or round ulcer of the stomach. This depends mainly upon the fact that the disease can be cured, as I believe, by timely, judicious, skilled intervention, and at a time and under conditions when delay and ignorance, on the one hand, or too great zeal, on the other, do great harm.

There are many instances, no doubt, where, under proper prophylactic measures, simple ulcer of the stomach may never develop; or, if already present, it may not progress nor give rise to threatening symptoms. If it has developed, and pain and dyspeptic symptoms are very marked, frequent, or continuous, and even after one or more hæmorrhages have occurred, a cure may follow a purely medical course of treatment. If, on the other hand, these means have been faithfully and carefully tried for many weeks, and the symptoms still persist with stationary or increased severity, surgical aid should be invoked, and in some cases surgery alone will bring about complete recovery, and even, in certain

instances, save life. Those are the cases of acute ulcer, in which the hæmorrhage is sudden, profuse, and repeated, and the menace to life too great to await the slower results of medicinal remedies, or of hygiene and time; also those of chronic ulcer, in which the recurrent hæmorrhages show that the degenerated, gaping artery of the diseased surface may be obstructed for a time with a clot, but will soon through its removal bleed afresh. Here there is but one way to obtain a cure and that is through an operation. Otherwise, when the stomach dilates, the orifice of the vessel becomes enlarged, hæmorrhage recurs, and death will ultimately ensue.

In cases of perforation of the stomach from any form of ulcer of any duration, the formal indication is to operate, and the sooner the operation is done the better the chances of saving life. Instances of cure without operation are known, but they are very infrequent, and unless special conditions prevailed, such as an empty stomach, a very small perforation, chronic adhesions to adjacent organs, etc., even those instances would not have been possible.

Of the twenty-nine cases of ulcer of the stomach collected by Dr. Traub from the records of St. Luke's Hospital for the past twenty years, twenty-four occurred in females and five in males. Of the men, three died; one was cured; one improved. Of the twenty-four female patients, one died, two were improved, and nineteen were cured. Only one of the twenty-nine cases was treated surgically. In that case, in a man, gastroenterostomy was done, and the patient died on the following day.

In order to obtain interesting facts up to date, especially in New York hospitals, I have written to prominent representatives of these institutions and made the following inquiries:

1. How many cases of ulcer of the stomach are in your hospital records during the past five or ten years?
2. How many have been operated in and the nature of the operation?
3. Results of operation?
4. Results of medical treatment?
5. Have you made any examinations of stomachal contents *before* and *after* operation?

* Read before a meeting of the New York Academy of Medicine.

I have also written to two physicians in charge of important private laboratories and to several well known hospital physicians and surgeons in New York, Baltimore, and Philadelphia. The reports I have received would take some time to read and separately are not sufficiently interesting to justify at present that expenditure. Collectively, even, they have not given me as much that is important as proceeds from facts contained in the latest published papers on this subject. (See reports.)

"During the past ten years there have been 52 cases of gastric ulcer admitted to the New York Hospital. Of these 35 were treated in the medical and 17 in the surgical wards. Of the 52 patients 11 died, which is a mortality of 21.75 per cent. There were 4 cases of relapse. Of 17 cases admitted, or transferred to the surgical division, 14 cases were operated in. Six of these patients died and 8 recovered. The statistical facts of these few cases do not allow of any particular generalization," writes Dr. Samuel W. Lambert, "except to emphatically point out the fact that surgical procedure offers in certain cases the only road to recovery."¹

Dr. Joseph A. Blake's personal experience at the Roosevelt Hospital with *perforating* gastric and duodenal ulcers is limited to 6 cases. Three patients died after operation; 3 recovered. In one, so called, recovered case the patient "now, one and one half years since the operation, has some symptoms of motor insufficiency, and I have recommended gastroenterostomy," writes Dr. Blake. In 5 cases operated in for *hemorrhage* by Dr. Blake there were 2 deaths and 3 recoveries. In two of the latter "only three months" have elapsed since the operations. "The treatment of *acute* gastric ulcer," writes Dr. Blake, "is essentially medical, since in these cases the results are extremely good. The story in chronic ulcer is different," and Blake proceeds to show from numerous statistics, that surgical treatment has "a distinctly lesser mortality."² A question of considerable interest, as Dr. Blake states, is whether the "hyperchlorhydria which accompanies ulcer is not a result instead of a cause of ulcer. Several cases are reported where relief from hyperchlorhydria followed operation.

According to Dr. C. P. Howard, of Baltimore, "hardly a sufficient number of cases treated by surgical interference have been followed for a sufficient period to justify a comparison with the results of medical treatment. Mayo Robson had a mortality in 1901 of 5 per cent.; W. J. Mayo, of Rochester, Minn., 6.5 per cent.; Peterson and Merchol, 11 per cent. Moynihan, in 1904, among 100 cases treated by gastroenterostomy alone, had a mortality of but 2 per cent." "These figures all compare favorably," writes Howard,³ "with those resulting from medical treatment, the mortality of which varies between 10 and 20 per cent."

Unfortunately, we are *not* told at what dates subsequent to operation, the first percentages were estimated. The after result of 26 cases from Johns

Hopkins Hospital, for an average period of five years is: Deaths, 23 per cent.; recurrences, 26.8 per cent.; permanent cures, 50 per cent., for periods ranging from six months to thirteen years. In a letter to me from Dr. Howard, of March 7, 1905, he states that he is almost sure that in none of these 26 cases was an operation performed. Dr. Howard's twelfth conclusion reads: "The mortality of the series" (82 cases), "was 29.3 per cent.; in the patients, however, who received treatment, there was a mortality of only 18.8 per cent.; in those receiving medical treatment *alone*, 8.6 per cent."

In the personal letter referred to, Dr. Howard reports the following facts taken from the records of Dr. Halsted's surgical service in Johns Hopkins Hospital. "Six patients discharged well, 2 improved, one of whom died on the thirty-fifth day; 6 died as an immediate result of operation. In addition to these, Dr. Finney has had quite a series of more successful issue, in which he has operated in private or in the Union Protestant Infirmary. As to the cases receiving *medical treatment only*, of 58 patients, 11 were discharged well, 38 improved, 3 unimproved, and 5 died. That is to say, a mortality of 8.6 per cent.

REPORTS.

It is only fair to add that from some hospitals, as from some physicians and surgeons, for one reason or another, I could get *no report* in response to my inquiries.

Reports; Combined Reports of Cases and Results: Total number of cases, 35; total number of operations, 18; total number of cases under medical treatment, 17.

Results of Operations: 10 deaths, 7 recoveries, 1 unknown.

Results of Medical Treatment: No deaths, 10 cured, 1 improved, 6 unknown.

Nature of Operation: 5 gastroenterostomies, 4 posterior, 1 anterior. Most of the other operations were for emergency cases by Dr. John F. Erdmann and consisted in "sutures of the ulcer area only."

The after results both of medical and surgical treatment are unknown.

The results as reported must almost invariably be referred to period of discharge. To this statement there are two exceptions: One in a case of duodenal ulcer of Dr. W. B. Coley's, one in a case of acute hemorrhage of Dr. F. B. Curtis's, in which, two months later, the patient was much improved.

In view of a letter received from Dr. Erdmann, March 15th, I can add 3 other cases of after-history after operation. These 3 are Dr. Erdmann's own operative recoveries. "Both males are still living and have had no trouble up to last report. The female is out of the hospital for some time now, but has not passed over a sufficiently long postoperative period to give the postoperative data any weight."

Thanks to the courtesy of Dr. I. Adler, I received this day from the German Hospital a report from which I take the following facts: From 1900 to 1905, in all 43 cases of ulcer of the stomach. Of these there were 39 medical and 4 surgical cases. Of the medical cases 26 were cured (in one no treat-

¹ *Am. J. Med. Sc.*, December, 1905, p. 984.

² *Am. J. Med. Sc.*, December, 1904, p. 985, et seq.

³ *Am. J. Med. Sc.*, December, 1904, p. 962.

ment); improved, 10; unimproved, 1; died, 1; unknown, 1.

Many of these cases were treated with subnitrate of bismuth, calcined magnesia or bicarbonate of sodium by the mouth and one third of them had nutrient enemata. Diet and after-results are not stated.

The 4 surgical cases:

Operations: 1 McGraw ligature, 1 excision of ulcer, 1 exploratory, 1 gastroenterostomy, all cured at discharge.

In Dr. Adler's letter to me of to-day, he speaks of the "very incomplete and unsatisfactory notes," owing to general upset condition of the hospital at present.

Dr. George P. Biggs's report to me from the New York Hospital, March 14th, is not very unlike what I have taken from Dr. S. W. Lambert's published paper. He, Dr. Biggs, has only had time to run over hurriedly records for the five years from January 1, 1900, to January 1, 1905. The medical cases number 34, the surgical 12. The figures are approximately correct. Dr. Biggs finds no cases showing study of gastric contents after operation. A single examination, a few days after operation, gives rather more acidity than before in one case. In the collected reports are included the data obtained from the City and Bellevue hospitals.

No facts unfortunately were obtained from Mount Sinai, Presbyterian, Postgraduate, and several other New York hospitals.

Total number of cases from these reports reads, 78; total number of operations, 22; total number of medical cases, 56.

Results of Operations: 10 deaths, 11 recoveries, 1 unknown.

Results of Medical Treatment: 1 death, 36 cured, 11 improved, 1 unimproved, 7 unknown.

Nature of Operation: 6 gastroenterostomies, 1 excision of ulcer, 1 McGraw ligature, 1 exploratory. The remaining operations were sutures of the ulcer.

As regards treatment, I am of the opinion that in this disease as in others, the results we obtain in hospitals are no proper index of those we get in private practice. It must be remembered that hospital patients are often badly cared for before they enter the hospital. In the first place, they do not seek medical advice soon enough, and when they get it, it is not always the most careful and the best. Again, the necessities of their existence, their mode of life, their poor, wretchedly prepared and ill advised dietary are often likely to increase rather than to diminish the symptoms of the disease from which they are suffering. Admitting, then, that an ulcer of the stomach becomes fully developed and chronic, as it frequently does in hospital patients, the dietary and medical treatment at this stage are oftentimes not so successful as we should desire. Hence, surgical interference in this class of patients is more often indicated and even absolutely essential.

On the other hand, the patient in affluent circumstances, who seeks and obtains the best medical advice at the outset, is immediately put upon the most appropriate dietary, and proper remedies are at once prescribed. In my observation, such patients sooner or later get well without surgical interference. They may suffer, more or less, from obstinate dyspepsia for quite a prolonged period, but their hemorrhages are infrequent and relatively slight, and perforation very rarely occurs. These patients are usually intelligent, and when they have put before them the nature and threatening possibilities of their disease, they follow willingly and rigidly the rules laid down for them by their medical adviser as regards diet, medicine, and occupation, and the ultimate result is satisfactory in many instances. Of course, there may be and frequently is a recurrence of the painful and unpleasant symptoms of stomachal intolerance for a brief period, but this is usually shortlived if properly treated and disappears very rapidly.

In the present state of our knowledge regarding gastric ulcer, it is the part of wisdom and duty to endeavor to decide which cases belong to the surgeon, and at what stage of the pathological process the aid of surgery should be invoked. It is probable that in too many of these instances, laparotomy has been delayed too long, owing to more than one good reason. Of these, I might particularly mention lack of operative experience, faulty surgical technique, and a decided opposition on the part of medical men to permit operations upon their patients which they consider unjustifiable, when the fatal or serious outcome of many of them is fairly estimated.

The cardinal principles governing the medical treatment of declared gastric ulcer are (1) absolute or relative rest, mental and bodily, if possible. (2) The use of rectal feeding in a measure or altogether, and the partial or complete relief of stomachal digestion, at least for a time. Gradual return to feeding, with much care and many limitations, should later be counseled and enforced, and whenever anæmia is notably a factor in the make-up of the disease, its special treatment should not be ignored.

I place great emphasis on the latter part of the treatment, when pain has disappeared and the ulcer is almost or entirely cicatrized, because I believe the nervous system is often affected as regards its function, and it cannot be fully restored unless the formation of healthy blood is effected, whether the anæmia be a primary or merely a complicating factor. The nervous system, after all, receives its sustenance, in the main, from the blood, and unless this is normal both in quantity and quality, the

derangements of the former are more likely to continue and become worse.

There is a great difference between the medicinal treatment of acute and chronic ulcer of the stomach. This was pointed out specially by Fenwick, who emphasized the truth of it, and showed how closely it was based upon anatomical and pathological conditions essentially distinctive. In very many cases, an acute ulcer will be improved and perhaps cured by a relatively short course of treatment with diet, rest, and the use of a few medicinal agents. No such happy outcome should be looked for in chronic ulcer of the stomach. Here months, and indeed years may elapse before the patients become completely restored to health.

The two complications of gastric ulcer most to be dreaded are: (1) hæmorrhage; (2) perforation. The former may be very profuse and alarming, and yet rarely does a fatal result immediately follow. Absolute rest and quiet in bed should, of course, be insisted on, and no nutriment permitted excepting by the bowel. Cold applications to the epigastrium are indicated. I have but little faith in the use of gelatin hypodermically. On the other hand, we have to-day in the repeated use of a solution of adrenalin after this manner a most potent remedy. When not given subcutaneously, it may of course be administered by the mouth several times a day in doses of from ten to twenty drops of a 1 to 1,000 solution. Ewald's suggestion of washing out the stomach with iced water does not appeal to me.

If the hæmorrhage is not arrested by these means, we must consider the propriety of a surgical operation. The indication to operate may also be present if the hæmorrhage is frequently repeated, even though it may not be profuse. In some cases, even though the hæmorrhage may be slight and rarely repeated, if the stomachal distress is great and continuous despite well ordered and judicious treatment continued for several weeks or months, an operation may be advisable.

The two operations hitherto brought forward in this condition are resection of the gastric ulcer, with suture of the wall of the stomach, and gastroenterostomy. The former has had a very high mortality, and surgeons to-day are generally in favor of making an artificial anastomosis between the stomach and the intestine by a posterior gastroenterostomy or by Finney's method of pyloroplasty. In many instances, one of the latter operations will give complete relief to the symptoms, and the explanation of this fact seems to be that the stomachal digestion becomes more rapid, and the food, being held in the stomach a shorter time, is less exposed to the prolonged action of the hydrochloric acid, which is oftentimes secreted in excess.

Unfortunately, in many instances, there is a return of the characteristic symptoms of ulcer. There may again be hæmatemesis, gastric distress, and even perforation. These symptoms are due to the formation of fresh ulcers. In point of fact when one ulcer is present others are likely to occur. Indeed, unless the underlying cause or causes of ulcer of the stomach are overcome or continuously neutralized, it is improbable that a permanent cure will follow. The lower segment of the stomach, after an anastomosis with the duodenum or ileum has been effected, takes on a similar rôle to the pylorus, and hence ulceration at this site is in an equal degree likely to occur if other conditions remain about the same. It is true that since the surgeons have abandoned anterior gastroenterostomy, renewed and grave symptoms of ulcer after operation have not occurred as frequently as previously; still, the mortality in these cases is very high in the aggregate. Even the latest report of operations for gastric hæmorrhage at the Boston City Hospital and the Massachusetts General Hospital, from 1898 to 1903, inclusive, reads: "Ten cases; ten deaths." The physicians should not be blamed, therefore, for their lack of enthusiasm for operation in such cases, even the most threatening, at least for the present. It is to be hoped and expected that with larger experience and improved technique, surgical results will be more favorable.

I am not aware that careful reports have been recorded of stomach examinations made on patients suffering from simple ulcer of the stomach before and after operation. Such examinations would be equally and even more valuable than those made by Dr. Friedenwald in five cases of dilated stomach operated upon by the Finney method of pyloroplasty, in all of which the gastric secretion was much improved.⁴

When the surgeons ask us urgently to turn over our cases to them sooner for operation, alleging that their success would then be greatly and speedily increased, we fail in a measure to recognize the validity of their reasoning. Their strong ground of argument is that to be successful they must operate while the patient is still in fairly good shape, and not unduly weakened by repeated hæmorrhages and insufficient food. On our side we maintain that if patients with gastric hæmorrhages receive careful and judicious medical treatment, they will rarely reach the stage where an operation is imperatively

⁴ *Medical News*, February 4, 1905, p. 238.

NOTE.—Three of Friedenwald's cases, as I have learned from him since, were cases of ulcer. In two there was dilatation; in all three superacidity. After operation the condition was perfectly normal. (Letter of February 14, 1905.) From Johns Hopkins Hospital there are "only two records of analyses of the stomach contents after operation in gastric ulcer. In both total acidity was less and also free HCl. The latter in one case had disappeared."—C. P. HOWARD.

needed, and we should not prejudice, as it were, the curative effects of hygiene and medicine in any particular case until it has proved, beyond peradventure, to be useless. Alas for the uncontrolled tendency of the day, which would seek to cure all human ailments with the knife, and allow less and less to the sanest, most instructed, and broadest way of regarding departures from health and well being. It should be borne in mind, also, even with a very profuse initial hæmorrhage, that it may not occur again, and even if it does occur, it may be in far less amount. Moreover, such cases are susceptible of cure by mild medicinal and hygienic treatment. Again, such ulcers, although sometimes existing singly in a given case, may exist with one or more ulcers at different sites. If this is true, it is too dangerous to excise and ligate all of them. Finally, even if search is made for numerous bleeding points, they cannot invariably be found—at all events, not soon enough to offer chances of a thorough and successful operation. In those cases where the stomach is, as it were, "weeping blood," nothing more can be done than a gastroenterostomy, and this operation, as we know, is of uncertain value in such a condition.

In chronic perforations, where adhesions with adjacent organs have already been formed, which limit the extent to which the extruded gastric contents are carried, and consequently localize the subsequent peritonitis, operation may be deferred for a time, or until the evidences of an abscess cavity are undoubted by reason of the physical signs or the result of exploratory puncture.

In considering cases of rapid or sudden death following an operation for profuse or repeated gastric hæmorrhage, presumably caused by ulcer, I am of the opinion that some lives might have been saved if, preliminary to the operation, artificial serum in sufficient quantity had been immediately injected, either subcutaneously or by the intravenous route, and repeated as often as indicated. In the first place, we should thus give rapid tone to the heart and blood vessels; and, secondly, we should help reform blood corpuscles as rapidly as possible. The patient would then be in far better shape, doubtless, to submit to an operation, and to obtain a successful result. The objection which might be urged to the serum injections, on the ground of promoting an immediate return of the bleeding through increased blood pressure, does not impress me as valid, in the face of an imminent situation, and in view of recorded results where the operation was proceeded with without preliminary or intercurrent serous injections.

I have not had occasion, as yet, either to resort to or to advise these serous injections in hæmor-

rhages from gastric ulcer, but from the standpoint of what I have now learned I should certainly advocate them in the future, unless it is proved to me that my judgment has been at fault. To those who, for one reason or another, will not use serous injections, either intravenous or subcutaneous, I am confident that repeated large saline enemata, or prolonged irrigation of the lower bowel, might prove a valuable substitute.

There is little doubt in my mind that many cases of acute ulcer of the stomach begin as an erosive ulceration. The cases reported by F. J. Smith, Monsell Moullin, and Sir Dyce Duckworth, as well as one of my own, prove this statement. These patients should first be treated medically. If the hæmorrhage was continuous, "and would almost certainly prove fatal unless active measures were taken to arrest it," and if the patient was in fair condition, and delay perhaps meant "rapid decline and death," it might or might not be judicious to operate. In Duckworth's case, operated on by Butlin, the result was recovery. In my own case, operated on by Blake, the result was death. Butlin sutured "unsound places" in the stomach; Blake performed posterior gastroenterostomy.

In conclusion, I would insist upon certain facts:

1. That probably no known treatment will prevent the formation of fresh gastric ulcers (Rutherford Morrison⁵).
2. That uncertainty of diagnosis often leads to clinical error (Francine,⁶ Howard⁷).
3. That acute gastric ulcer must be recognized clinically, for it usually heals, and the treatment is purely medical. A considerable minority fail to do so and constitute a share of the chronic ulcers. A chronic ulcer is frequently, if not usually, chronic from its inception (Mayo⁸).
4. That despite the brilliant results of gastroenterostomy in the treatment of gastric ulcers, it should be remembered that there may be forcible objections to it: "Is it probable that such a revolution of the chemical and physical processes of digestion as is involved in a successful gastroenterostomy is likely to be followed by no evils?" It is desirable to know a great deal more than is yet known of the after-history of patients operated on (R. Morri-son⁹).
5. That any form of gastroenterostomy is a grave operation, even the most approved and the newest, on account of opening internal organs and stitching them together in unusual positions (J. G. Mumford¹⁰).
6. That conservative clinical diagnoses, in addition

⁵ *Lancet*, February 11, 1905, p. 351.

⁹ *ibid.*

¹⁰ *Boston Med. and Surg. J.*, March 2, 1905, p. 261.

to correctly interpreted autopsy findings, will enable us to form safe judgments of cases of ulcer of the stomach, as to the medical or surgical treatment.

7. That in emergency cases, whether of hæmorrhage or perforation,¹¹ frequently no previous symptoms existed which would permit even a probable diagnosis, hence no rational preventive medical treatment could be carried out.

THE MEDICAL TREATMENT OF GASTRIC ULCER.*

By JULIUS FRIEDENWALD, A. M., M. D.,

BALTIMORE, MD.,

CLINICAL PROFESSOR OF DISEASES OF THE STOMACH, COLLEGE OF PHYSICIANS AND SURGEONS.

The names of a number of eminent clinicians have been associated with the treatment of ulcer of the stomach. It was Cruveilhier who first advised an exclusive milk diet in the treatment of this condition and Brinton who first pointed out clearly the advantages of the rest treatment. The names of Wilson Fox, von Ziemssen, Leube, Fleiner, Riegel, and Boas must be mentioned too, who have done much to develop the treatment of ulcer of the stomach.

It is generally admitted by most authorities that the rest treatment should always be instituted in all cases of ulcer of the stomach in order to attain as far as possible those conditions most favorable for rapid healing. The patient should be put to bed at rest for a variable period of time depending upon the severity of the symptoms, ordinarily from two to five weeks, and kept strictly upon a liquid diet, mainly of milk. The rest in bed as well as the rigid diet not only assists in the healing of the ulcer but also in a measure guards against the onset of such accidents as perforation and hæmorrhage. The additional advantage of the rest lies in the fact that a patient when in bed requires but a sixth of the number of calories that he requires when about and, therefore, much less nourishment is needed under these conditions, thus entailing less labor upon the diseased stomach. The stomach should be spared all possible irritation, the food being taken neither too hot nor too cold and, as already stated, only in the liquid form. The excess of acid in the stomach should as far as possible be lessened and all irritation from drugs should be avoided. Milk can ordinarily be given without being peptonized, best diluted with lime water; beginning with small quantities at two hour intervals, one to two quarts of milk may be gradually consumed in twenty-four hours. After the first week, when the nausea and pain have

¹¹ None of Dr. J. F. Erdmann's emergency cases, "as far as the histories were obtainable, presented any previous history to that of sharp pain at the time of perforation."

* Read, by invitation, at the Journal Club, February 25, 1905.

subsided, some well cooked wheat preparation or strained barley or oatmeal or somatose may be added to the milk to increase its nutritive value, or clear broth or broth with an egg thoroughly broken up may be added to the diet; if the patient has improved and is free from nausea or vomiting a soft diet such as rice cooked in milk, milk toast, or soft boiled eggs may be allowed at the beginning of the third week. At the beginning of the fourth week solid food in easily digestible form, such as raw scraped beef, stewed chicken, broiled sweetbreads, calves' brains, baked potatoes, may be allowed and finally the usual diet may be given; but raw fruit, salads, pastry, and the heavy vegetables should be avoided for a long period of time. The patient should remain in bed from two to four weeks according to the severity of the symptoms; ordinarily at the beginning of the third week he may be allowed to recline on a couch and toward the end of this week to sit up for a short time and finally for a longer time each day. In the fourth week the patient is usually permitted to walk about. Hot poultices are applied to the abdomen for several weeks during the early part of the treatment and 200 to 300 c.c. of hot Carlsbad water are taken morning and evening. In all cases of ulcer of the stomach of a severe type, which are accompanied by excessive nausea, vomiting, and pain, or accompanied by vomiting of blood, all nourishment by mouth should be withheld for a period varying from five to ten days, the patient being fed by means of nutrient enemata given from three to five times daily. During this period the thirst may be partly allayed by allowing bits of crushed ice or permitting the patient to rinse his mouth with water. McCall, Anderson and Donkin first called attention to this plan in the treatment of ulcer of the stomach. Whenever it is possible it is best to begin treatment in all cases of ulcer according to this method for four or five days, then gradually allowing small quantities of milk and finally continuing the rest cure diet as has already been described. It is a much more simple matter now to determine the length of time a patient should remain on a strict milk diet and at rest in bed than formerly. According to the recent investigation of Boas, small invisible hæmorrhages frequently occur in cases of ulcer which can be detected only by special chemical examinations (the guaiac or aloin tests) of the fecal discharge. These hæmorrhages are known as "occult." By means of the examinations for "occult hæmorrhages," we are enabled to establish the individual term of treatment, dismissing the patient only when repeated tests fail to disclose further occult hæmorrhages.

While this plan of treatment is usually recommended it must not be forgotten that there are some

objections to an exclusive milk diet extending over a number of weeks. The anæmia frequently found accompanying this condition is often very extreme and the small quantities of milk which are consumed cannot prevent the onset of rapid emaciation. For this reason Fuetterer recommends the juice expressed from five pounds of beef to be taken daily to combat this condition. Lenhartz, too, has recently cautioned against the strict abstinence diet in the treatment of ulcer, even in those instances in which there is hæmorrhage. He bases his conclusions on the fact that since ulcer of the stomach is most frequently accompanied by superacidity and also by a generally enfeebled condition it is best to give proteid food early to overcome the acidity as well as to build up the system. The accompanying table illustrates his method of feeding. The eggs and milk are given ice cold and in teaspoonful doses. By means of this method he has treated 60 cases with gratifying results. In those cases where there has been hæmorrhage the patient is kept in bed for fourteen days, and an ice bag is placed on the abdomen for ten days.

Day after last hæmorrhage	1	2	3	4	5	6	7	8	9	10	11	12	13	14

There are a number of mild cases of ulcer of the stomach in which it is impossible to carry out the rest treatment. Under these conditions the ambulatory form of treatment may be undertaken according to one of three methods. In all cases the patient is permitted only to take liquid or semisolid food.

(1) Nitrate of silver is prescribed in solution in one sixth to one third grain doses for a period of three weeks, or

(2) Bismuth subnitrate may be administered in large doses (one teaspoonful) three times a day. Fleiner recommends giving the bismuth suspended in water after previous lavage of the stomach. After the stomach has been thoroughly cleansed, 10 to 20 grammes of subnitrate of bismuth, suspended in 100 to 200 c.c. of water, are passed into the stomach through the tube, after which the patient is required to lie on his right side for a half hour. In those instances in which there is any contraindication to the use of the tube, Fleiner advises the administration of 10 grammes of bismuth subnitrate suspended in a glass of water in the morning before breakfast.

(3) The oil cure has been recently recommended

by Cohnheim in the treatment of ulcer of the stomach. Olive oil is taken three times daily from half to one hour before meals; in wineglassful doses in the morning and in dessertspoonful doses at noon and in the evening. In very mild cases an emulsion of sweet almonds may be substituted for the oil. The oil fulfils several indications. It forms a coating over the stomach and thus assists in overcoming pylorospasm, and by relieving friction it overcomes pain; it checks the excessive secretion of acid, and improves the general nutrition. The treatment of a number of special symptoms must yet be referred to.

(1) *Hæmorrhage*.—In all cases of hæmorrhage absolute rest in bed must be insisted upon; an ice bag should be placed upon the epigastrium and a hypodermic injection of morphine administered. It is quite doubtful whether any drugs which we have at hand have any special influence in checking bleeding from the stomach. Among the remedies which may be utilized for this purpose are hypodermic injections of ergot or gelatin (100 grammes of a 2 per cent. watery solution). Recently Einhorn

has recommended the hypodermic injection of a syringe of adrenalin chloride, 1 to 2000, twice daily, or the internal administration of 15 drops of the same solution three times daily. In cases of great weakness or actual collapse from hæmorrhage saline infusions must be resorted to. Very profuse hæmorrhages recurring at short intervals or even frequent small hæmorrhages of the stomach which are not relieved by the usual treatment require surgical interference.

2. *Acidity*.—For the relief of the acidity, which is a usual accompaniment of ulcer of the stomach, one is frequently required to administer alkalies alone or combined with belladonna or codeine.

(3) *Constipation*.—This symptom may be relieved by the use of enemata or by the internal administration of oil or Carlsbad water.

The question which always arises after the treatment of ulcer of the stomach and which is sometimes difficult to decide is, What evidence have we that an ulcer is healed? In a general way this question may be answered in the affirmative when there is an entire absence of pain after taking solid food; when there is no longer pain on pressure in the

epigastric region; and, finally, when repeated tests fail to reveal further "occult hæmorrhages" in the fæcal discharge. Another question of equal importance which the physician must decide is the time when surgical procedures should be instituted, in other words when cases of gastric ulcer should no longer be treated medically. The indications for surgical procedures are as follows:

1. *Perforations*.—All perforations should be handled at once by surgical methods.

2. *Perigastric Adhesions*.—Perigastric adhesions produced by gastric ulcers, especially those accompanied by tumor formation, should be handled surgically.

3. *Hæmorrhages*.—Hæmorrhages which are very profuse, occurring at short intervals or even small frequent hæmorrhages which are not relieved by medical means require surgical treatment.

4. *Persistent Nausea and Vomiting*.—In all cases in which there is persistent nausea, vomiting, and pain, not relieved by the rest treatment or by a strict abstinence cure, it is necessary to seek surgical aid.

5. *Recurring Ulcers*.—All cases of ulcers of the stomach recurring at shorter or longer intervals notwithstanding a proper rest or abstinence cure require surgical treatment.

I beg leave to submit a short statistical report of the results of treatment of 287 cases of gastric ulcer under my care in hospital and private practice during the past six years. I have been careful to eliminate all cases in which there has been any doubt as to diagnosis as well as those which could not be carefully observed during the entire course of treatment.

	Cured.	Not cured.	Died.	Percentage of recoveries.
Of these 75 were treated by the				
best cure.....	67	8	3	89
198 were treated as ambulatory patients:				
108 were treated by the nitrate of silver method.....	64	14	0	59
82 were treated by the sub-nitrate of bismuth method..	55	27	0	67
8 were treated by the oil method.....	4	4	0	50
14 were operated on.....	10	..	4	71

The Albany, N. Y., Hospital Training School graduated the following nurses on May 17th:

Misses Percy Loveday, Edna Grace Bridgeford, Harriet M. Stark, Elizabeth Ulrich, Anna Hervey Strong, and Florence E. Bochlowski, of Albany; Mabel Stevens Diack, of Rensselaer, and Susan James Sullenden, of Eagle Rock, Va.; Effie Anne Nettleton, of Little Falls; Florence Amelia Heidle, of Ohio; Marietta Frost Fitchett, of Poughkeepsie; Margaret Isabel Black, of Fergus, Canada; Rosemary Barrett, of Oneonta; Irene Sarah Williams, of Fort Plain; Grace Maude Wells, of Fort Plain; Emily Anne Fraser, of Prince Edward's Island, Canada; Margaret Gertrude McClellan, of Gananoque, Canada; Sara Ingalls, of Ponda; Lulu Florence Schrader, of New Haven, Conn.; Mary Walker, of Schenectady; Edith Alma Loomis, of Canandaigua; Mabel King Hill, of Walden.

THE EMPLOYMENT OF CELLULOID PLATES FOR COVERING OPENINGS IN THE SKULL IN OPERATIONS FOR EPILEPSY, BRAIN TUMOR, ETC.*

By WILLIAM PERRIN NICOLSON, M. D.,

ATLANTA, GA.

It is somewhat surprising that in all the history of surgery practically no attempt has been made to protect with artificial coverings openings made in the skull by design or accident. There is a universal belief on the part of the laity that the insertion of silver plates is a matter of everyday occurrence. This has been so extensively accepted that it is not unusual to find physicians who also believe that this has been done. A review of current text books in surgery does not reveal any mention of such a procedure, and surgical treatises in the medical press have very few allusions to the subject. There seems to be an almost universal recognition of the fact that such a principle should be of value. At the meeting of the American Medical Association in 1896 in the section in surgery the writer heard the question asked if any one present had ever employed, seen used, or authentically known of the implantation of a plate for the protection of the brain. There was a universal negative reply.

Theoretically, the insertion of some means of protection should be an ideal procedure. In exposing the brain we deal with the organ which Nature has most carefully guarded against force of impact, and one the irritation of whose surface causes many of the most serious conditions for which we are called upon to operate. By the usual means of operating we in many instances substitute a pressure and resulting irritation for that we are removing, for we leave the impressible brain covered over only by the scalp, and subjected to outside influences before impossible. While it is true that Nature finally substitutes a partial protection in the form of a fibrous covering, this must of necessity by atmospheric pressure have been depressed before consolidation, and we have the renewed pressure, which we found necessary to remove, with the difference that in many cases the area of pressure is greater than before. If under such conditions we are able simply and rapidly to cover openings of whatever size with an easily prepared plate, which is in itself unirritating, sufficiently unyielding to resist atmospheric pressure, and at the same time elastic to a certain extent, we certainly have accomplished a great deal.

* Read before the Association of Southern Railway Surgeons.

Such requisite conditions we find in celluloid, a material which remains indefinitely in the tissues without irritation or disturbance, and the physical character of which is such that it can be easily cut with scissors to the required size and shape for adjustment to the opening. Its harmlessness in the tissues was demonstrated to me by the absence of any irritation from a celluloid testicle introduced by me into a patient's scrotum, and worn now for five years without any trouble whatever. Given such a material, we are enabled to enlarge the opening in the skull to whatever size we may desire, knowing that we can cover the opening and protect the brain from subsequent injury or from undue protrusion from want of support. In operations for epilepsy it not only protects the brain from subsequent pressure, but leaves an increased space measured only by the thickness of the individual's skull.

One might naturally suggest that this can be accomplished in surgical destruction of the bone by making a large osteoplastic flap, but this is applicable only when we know beforehand that we are going to make an extensive dissection. Many conditions arise during brain operations that call upon us unexpectedly to enlarge our incision in the skull, in which case the bone cannot be utilized for subsequent reintroduction into the wound.

TECHNIQUE.

The surgeon will select the method of opening the skull which he prefers, whether by saw or rongeur. Personally I prefer the De Vilbis rongeur where long incisions in the skull are to be made, and for enlarging or rendering symmetrical the opening already made I use the ordinary angular rongeur. The incision in the scalp should be of horseshoe shape, and sufficiently free in its sweep to give the desired room for enlargement in any direction that may be necessary, always remembering that it is far better to have both the bone and scalp opening too large than too small.

The question of control of scalp hæmorrhage is one always important because of the very free vascular distribution, and of the difficulty of clamping the vessels in the dense scalp tissue. In order to handle this with rapidity I have devised a scalp forceps, with the assistance of Messrs. George Tiemann and Company, with convex and concave jaws of varying lengths, by means of which large areas may be secured at one time in a few seconds. Time is also saved by the employment of the De Vilbis trephine, which can be pushed rapidly to the dura without fear of injury of the brain.

After completion of the operation the plate of
